3 说明

TPS7A21-Q1 是一款小型低压降 (LDO) 线性稳压器，可提供 500mA 的输出电流。该器件可提供低噪声、高 PSRR 和出色的负载和线路瞬态性能，符合射频和汽车应用中其他敏感模拟电路的要求。采用创新的设计技术，无需添加外部噪声旁路电容即可提供低噪声性能。TPS7A21-Q1 具有低静态电流，非常适合用于低功耗系统。输入电压范围为 2.0V 至 6.0V，输出电压范围为 0.8V 至 5.5V，可满足各种系统要求。在负载、线路和温度范围内的最大输出电压容差为 1.5% 至 2.25%。

内部软启动电路可帮助控制浪涌电流，因此可在启动过程中更大程度地降低输入电压降。该 LDO 在与小型陶瓷电容器搭配使用时可保持稳定，因此可实现小尺寸的总体解决方案。

借助具有内部控制下拉电阻器的智能使能输入电路，即使在 EN 引脚未连接时也能让 LDO 保持禁用状态。该电路还有助于省去原本需要用于下拉 EN 输入的外部元件。

表 4-1. Pin Functions

PIN				TYPE ⁽¹⁾	DESCRIPTION
NAME	DRB	DSG0008B	DSG0008A (C Version)		
EN	5	5	2	I	Enable pin. Drive EN greater than $V_{EN(HI)}$ to turn on the regulator. Drive EN less than $V_{EN(LO)}$ to put the low-dropout regulator (LDO) into shutdown mode.
GND	4	4	1	—	Ground pin.
IN	8	7, 8	3, 4	I	Input pin. For best transient response and to minimize input impedance, use the recommended value or larger ceramic capacitor from IN to ground as listed in the Recommended Operating Conditions table and the Input and Output Capacitor Requirements section. Place the input capacitor as close to the output of the device as possible.
NC	2, 3, 6, 7	3, 6	7, 8	—	No internal connection. Ground this pin for better thermal performance.
OUT	1	1, 2	5, 6	O	Regulated output voltage pin. Connect a low-equivalent series resistance (ESR) capacitor to this pin. For best transient response, use the nominal recommended value or larger capacitor from OUT to GND. An internal pulldown resistor prevents a charge from remaining on OUT when the regulator is in shutdown mode ($V_{EN} < V_{EN(LOW)}$).
Thermal Pad					The thermal pad is electrically connected to the GND node. Connect to the GND plane for improved thermal performance.

(1) I = input, O = output, NC = no connect.

5 Specifications

5.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)^{(1) (3)}

		MIN	MAX	UNIT
V_{IN}	Input voltage	- 0.3	6.5	V
V_{OUT}	Output voltage	- 0.3	Lesser of $V_{IN} + 0.3$, or 6.5	V
V_{EN}	Enable input voltage	- 0.3	6.5	V
	Maximum output current ⁽³⁾	Internally limited		A
T_J	Operating junction temperature	-40	150	°C
T_{stg}	Storage temperature	- 65	150	°C

- (1) Operation outside the Absolute Maximum Ratings may cause permanent device damage. Absolute maximum ratings do not imply functional operation of the device at these or any other conditions beyond those listed under Recommended Operating Conditions. If briefly operating outside the Recommended Operating Conditions but within the Absolute Maximum Ratings, the device may not sustain damage, but it may not be fully functional. Operating the device in this manner may affect device reliability, functionality, performance, and shorten the device lifetime.
- (2) All voltages are with respect to the GND pin.
- (3) Internal thermal shutdown circuitry helps protect the device from permanent damage.

5.2 ESD Ratings

			VALUE	UNIT
$V_{(ESD)}$	Electrostatic discharge	Human-body model (HBM), per ANSI/ESDA/JEDEC JS-001 ⁽¹⁾	±2000	V
		Charged-device model (CDM), per JEDEC specification JESD22-C101 ⁽²⁾	±750	

- (1) JEDEC document JEP155 states that 500V HBM allows safe manufacturing with a standard ESD control process.
- (2) JEDEC document JEP157 states that 250V CDM allows safe manufacturing with a standard ESD control process.

5.3 Recommended Operating Conditions

over the operating free-air temperature range (unless otherwise noted)⁽¹⁾

		MIN	NOM	MAX	UNIT
V_{IN}	Input supply voltage	2.0		6.0	V
V_{EN}	Enable input voltage	0		6.0	V
V_{OUT}	Nominal output voltage range	0.8		5.5	V
I_{OUT}	Output current	0		500	mA
C_{IN}	Input capacitor ⁽²⁾		1		μF
C_{OUT}	Output capacitor ⁽³⁾	1		200	μF
ESR	Output capacitor effective series resistance			100	mΩ
T_J	Operating junction temperature	- 40		150	°C

- (1) All voltages are with respect to the GND pin.
- (2) An input capacitor is not required for LDO stability. However, an input capacitor with an effective value of 0.47 μF minimum is recommended to counteract the effect of source resistance and inductance, which in some cases causes symptoms of system-level instability such as ringing or oscillation, especially in the presence of load transients.
- (3) Effective output capacitance of 0.4 μF minimum and 200 μF maximum over all temperature and voltage conditions is required for stability with ESR values as high as 100mΩ. If the ESR is reduced to 20mΩ or lower, stable operation is achieved with effective output capacitance as low as 0.3 μF.

6 Detailed Description

6.1 Overview

Designed to meet the needs of sensitive RF and analog circuits, the TPS7A21-Q1 provides low noise, high PSRR, low quiescent current, and excellent line and load transient response. The TPS7A21-Q1 achieves excellent noise performance without the need for a separate noise filter capacitor.

The TPS7A21-Q1 is designed to operate properly with a single 1 μ F input capacitor and a single 1 μ F ceramic output capacitor. Make sure the effective output capacitance is at least 0.4 μ F across all operating voltage and temperature conditions.

6.2 Functional Block Diagram

6.3 Feature Description

6.3.1 Smart Enable (EN)

The enable pin (EN) is active high. The output is enabled when the voltage applied to EN is greater than $V_{EN(HI)}$ and disabled when the applied voltage is less than $V_{EN(LOW)}$. If external control of the output voltage is not needed, connect EN to IN. This device has a smart enable circuit to reduce quiescent current. When the voltage on the enable pin is driven above $V_{EN(HI)}$, the output is enabled and the smart enable internal pulldown resistor ($R_{EN(PULLDOWN)}$) is disconnected. When the enable pin is floating, the $R_{EN(PULLDOWN)}$ is connected and pulls the enable pin low to disable the output. In addition to reducing quiescent current, the smart pulldown helps make sure that the logic level is correct even when EN is driven from a source that has limited current drive capability. The $R_{EN(PULLDOWN)}$ value is listed in the [Electrical Characteristics](#) table.

6.3.2 Low Output Noise

Any internal noise at the TPS7A21-Q1 reference voltage is reduced by a first-order, low-pass RC filter before being passed to the output buffer stage. The low-pass RC filter has a – 3dB cutoff frequency of approximately 0.1Hz. During start-up, the filter resistor is bypassed to reduce output rise time. The filter begins normal operation after the output voltage reaches the nominal value.

6.3.3 Active Discharge

The regulator has an internal metal-oxide-semiconductor field-effect transistor (MOSFET) that connects a pulldown resistor between the output and ground pins when the device is disabled to actively discharge the output voltage. Make sure the voltage on IN is high enough to turn on the pulldown MOSFET. When V_{IN} is too low to provide sufficient V_{GS} on the pulldown MOSFET, the pulldown circuit is not active. The active discharge circuit is activated by the enable pin, or by the voltage on IN falling below the undervoltage lockout (UVLO) threshold.

Do not rely on the active discharge circuit for discharging a large amount of output capacitance after the input supply collapses. Reverse current potentially flows from the output to the input. This reverse current flow potentially causes damage to the device. Limit any such transient reverse current to no more than 5% of the device rated current.

6.3.4 Dropout Voltage

Dropout voltage (V_{DO}) is defined as the input voltage minus the output voltage ($V_{IN} - V_{OUT}$) at the rated output current (I_{RATED}), when the pass transistor is fully on. I_{RATED} is the maximum I_{OUT} listed in the [Recommended Operating Conditions](#) table. The pass transistor is in the ohmic or triode region of operation, and acts as a switch. The dropout voltage indirectly specifies a minimum input voltage greater than the nominal programmed output voltage at which the output voltage is expected to stay in regulation. If the input voltage falls to less than the value required to support output regulation, then the output voltage falls as well.

For a CMOS regulator, the dropout voltage is determined by the drain-source, on-state resistance ($R_{DS(ON)}$) of the pass transistor. Therefore, if the linear regulator operates at less than the rated current, the dropout voltage for that current scales accordingly. [方程式 1](#) calculates the $R_{DS(ON)}$ of the device.

$$R_{DS(ON)} = \frac{V_{DO}}{I_{RATED}} \quad (1)$$

6.3.5 Foldback Current Limit

The TPS7A21-Q1 has an internal current limit circuit that protects the regulator during transient high-load current faults or shorting events. The current limit is a hybrid brick-wall foldback scheme. The current limit transitions from a brick-wall scheme to a foldback scheme at the foldback voltage ($V_{FOLDBACK}$).

In a high-load current fault with the output voltage above $V_{FOLDBACK}$, the brick-wall scheme limits the output current to the current limit (I_{CL}). When the output voltage drops below $V_{FOLDBACK}$, a foldback current limit activates that scales back the current when the output voltage approaches GND. When the output is shorted, the

device supplies a typical current called the *short-circuit current limit* (I_{SC}). I_{CL} and I_{SC} are listed in the [Electrical Characteristics](#) table.

The output voltage is not regulated when the device is in current limit. When a current limit event occurs, the regulator begins to heat up because of the increase in power dissipation. When the device is in brick-wall current limit, the pass transistor dissipates power $[(V_{IN} - V_{OUT}) \times I_{CL}]$. When the output is shorted and the output voltage is less than $V_{FOLDBACK}$, the pass transistor dissipates power $[(V_{IN} - V_{OUT}) \times I_{SC}]$. If thermal shutdown is triggered, the device turns off. After the device cools down, the internal thermal shutdown circuit turns the device back on. If the output current fault condition persists, the device cycles between current limit and thermal shutdown. For more information on current limits, see the [Know Your Limits application note](#).

图 6-1 shows a diagram of the foldback current limit.

图 6-1. Foldback Current Limit

6.3.6 Undervoltage Lockout

An independent undervoltage lockout (UVLO) circuit monitors the input voltage, allowing a controlled and consistent turn on and turn off of the output voltage. If the input voltage drops during load transients (when the device output is enabled), the UVLO has built-in hysteresis to prevent unwanted turn off.

6.3.7 Thermal Overload Protection (T_{SD})

Thermal shutdown disables the output when the junction temperature T_J rises to the shutdown temperature threshold T_{SD} . The thermal shutdown circuit hysteresis requires the temperature to fall to a lower temperature before turning on again. The thermal time constant of the semiconductor die is fairly short. Thus, the device cycles on and off when thermal shutdown is reached until power dissipation is reduced.

High power dissipation occurs during start up from large $V_{IN} - V_{OUT}$ voltage drops across the device or from high inrush currents charging large output capacitors. Under some conditions, the thermal shutdown protection disables the device before start up completes.

For reliable operation, limit the junction temperature to the maximum listed in the [Recommended Operating Conditions](#) table. Operation above this maximum temperature causes the regulator to exceed operational specifications.

Although the thermal shutdown circuitry is designed to protect against temporary thermal overload conditions, this circuitry is not intended to replace proper thermal design. Continuously running the regulator into thermal shutdown or above the maximum recommended junction temperature reduces long-term reliability.

6.4 Device Functional Modes

6.4.1 Device Functional Mode Comparison

表 6-1 shows the conditions that lead to the different modes of operation. See the [Electrical Characteristics](#) table for parameter values.

表 6-1. Device Functional Mode Comparison

OPERATING MODE	PARAMETER			
	V_{IN}	V_{EN}	I_{OUT}	T_J
Normal operation	$V_{IN} > V_{OUT(nom)} + V_{DO}$ and $V_{IN} > V_{IN(min)}$	$V_{EN} \geq V_{EN(HI)}$	$I_{OUT} < I_{OUT(max)}$	$T_J < T_{SD(shutdown)}$
Dropout operation	$V_{IN(min)} < V_{IN} < V_{OUT(nom)} + V_{DO}$	$V_{EN} \geq V_{EN(HI)}$	$I_{OUT} < I_{OUT(max)}$	$T_J < T_{SD(shutdown)}$
Disabled (any true condition disables the device)	$V_{IN} < V_{UVLO}$	$V_{EN} \leq V_{EN(LOW)}$	Not applicable	$T_J \geq T_{SD(shutdown)}$

6.4.2 Normal Operation

The device regulates to the nominal output voltage when the following conditions are met:

- The input voltage is greater than the nominal output voltage plus the dropout voltage ($V_{OUT(nom)} + V_{DO}$)
- The output current is less than the current limit ($I_{OUT} < I_{CL}$)
- The device junction temperature is less than the thermal shutdown temperature ($T_J < T_{SD}$)
- The enable voltage has previously exceeded the enable rising threshold voltage and has not yet decreased to less than the enable falling threshold

6.4.3 Dropout Operation

If the input voltage is lower than the nominal output voltage plus the specified dropout voltage, but all other conditions are met for normal operation, the device operates in dropout mode. In this mode, the output voltage tracks the input voltage. During this mode, the transient performance of the device becomes significantly degraded because the pass transistor is in the ohmic or triode region, and acts as a switch. Line or load transients in dropout result in large output-voltage deviations.

When the device is in a steady dropout state (defined as when the device is in dropout, $V_{IN} < V_{OUT(NOM)} + V_{DO}$, directly after being in a normal regulation state, but *not* during start up), the pass transistor is driven into the ohmic or triode region. When the input voltage returns to a value greater than or equal to the nominal output voltage plus the dropout voltage ($V_{OUT(NOM)} + V_{DO}$), the output voltage overshoots for a short period of time while the device pulls the pass transistor back into the linear region.

For output currents less than approximately 200mA, the slope of the dropout voltage curve is lower than for higher currents. This slope helps maintain better performance when the LDO is in dropout.

6.4.4 Disabled

Shut down the output of the device by forcing the enable pin voltage to less than $V_{EN(LOW)}$. When disabled, the pass transistor is turned off, internal circuits are shut down, and the output voltage is actively discharged to ground by an internal discharge circuit from the output to ground.

7 Applications and Implementation

备注

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes, as well as validating and testing their design implementation to confirm system functionality.

7.1 Application Information

7.1.1 Recommended Capacitor Types

The device is designed to be stable using low equivalent series resistance (ESR) ceramic capacitors at the input and output. Multilayer ceramic capacitors have become the industry standard for many types of applications and are recommended, but use good judgment. Ceramic capacitors that employ X7R-, X5R-, and C0G-rated dielectric materials provide good capacitive stability across temperature, whereas the use of Y5V-rated capacitors is discouraged because of large variations in capacitance.

Regardless of the ceramic capacitor type selected, the effective capacitance varies with operating voltage and temperature. Consult the manufacturer data sheet to verify performance. Generally, expect the effective capacitance to decrease by as much as 50%. The input and output capacitors recommended in the [Recommended Operating Conditions](#) table account for an effective capacitance of approximately 50% of the nominal value.

7.1.2 Input and Output Capacitor Requirements

Although the LDO is stable without an input capacitor, good design practice is to connect a capacitor from IN to GND, with a value at least equal to the nominal value specified in the [Recommended Operating Conditions](#) table. The input capacitor counteracts reactive input sources and improves transient response, input ripple, and PSRR, and is recommended if the source impedance is greater than $0.5\ \Omega$. When the source resistance and inductance are sufficiently high, the overall system is susceptible to instability (including ringing and sustained oscillation) and other performance degradation if there is insufficient capacitance between IN and GND. A capacitor with a value greater than the minimum is necessary if there are large fast-rise-time load or line transients or if the LDO is located more than a few centimeters from the input power source.

An output capacitor of an appropriate value helps provide stability and improve dynamic performance. Use an output capacitor within the range specified in the [Recommended Operating Conditions](#) table.

7.1.3 Load Transient Response

The load-step transient response is the output voltage response by the LDO to a step in load current, whereby output voltage regulation is maintained. There are two key transitions during a load transient response: the transition from a light to a heavy load and the transition from a heavy to a light load. The regions shown in [图 7-1](#) are broken down as follows. Regions A, E, and H are where the output voltage is in a steady state.

图 7-1. Load Transient Waveform

During transitions from a light load to a heavy load, the:

- Initial voltage dip is a result of the depletion of the output capacitor charge and parasitic impedance to the output capacitor (region B)
- Recovery from the dip results from the LDO increasing the sourcing current, and leads to output voltage regulation (region C)

During transitions from a heavy load to a light load, the:

- Initial voltage rise results from the LDO sourcing a large current, and leads to the output capacitor charge to increase (region F)
- Recovery from the rise results from the LDO decreasing the sourcing current in combination with the load discharging the output capacitor (region G)

A larger output capacitance reduces the peaks during a load transient but slows down the response time of the device. A larger DC load also reduces the peaks because the amplitude of the transition is lowered and a higher current discharge path is provided for the output capacitor.

7.1.4 Undervoltage Lockout (UVLO) Operation

The UVLO circuit makes sure that the device remains disabled before the input supply reaches the minimum operational voltage range, and makes sure that the device shuts down when the input supply collapses. 图 7-2 shows the UVLO circuit response to various input voltage events. The diagram is separated into the following parts:

- Region A: The device does not start until the input reaches the UVLO rising threshold.
- Region B: Normal operation, regulating device.
- Region C: Brownout event above the UVLO falling threshold (UVLO rising threshold – UVLO hysteresis). The output falls out of regulation but the device remains enabled.
- Region D: Normal operation, regulating device.
- Region E: Brownout event below the UVLO falling threshold. The device is disabled in most cases and the output falls because of the load and active discharge circuit. The device is re-enabled when the UVLO rising threshold is reached by the input voltage and a normal start-up follows.
- Region F: Normal operation followed by the input falling to the UVLO falling threshold.
- Region G: The device is disabled when the input voltage falls below the UVLO falling threshold to 0V. The output falls because of the load and active discharge circuit.

图 7-2. Typical UVLO Operation

7.1.5 Power Dissipation (P_D)

Circuit reliability demands that proper consideration be given to device power dissipation, location of the circuit on the printed circuit board (PCB), and correct sizing of the thermal plane. Make sure the PCB area around the regulator is as free as possible of other heat-generating devices that cause added thermal stresses.

As a first-order approximation, power dissipation in the regulator depends on the input-to-output voltage difference and load conditions. Use [方程式 2](#) to approximate P_D :

$$P_D = (V_{IN} - V_{OUT}) \times I_{OUT} \quad (2)$$

Power dissipation is minimized, and thus greater efficiency achieved, by proper selection of the system voltage rails. Proper selection allows the minimum input-to-output voltage differential to be obtained. The low dropout of the TPS7A21-Q1 allows for maximum efficiency across a wide range of output voltages.

The main heat conduction path for the device is through the thermal pad on the package. As such, solder the thermal pad to a copper pad area under the device. This pad area contains an array of plated vias that conduct heat to any inner plane areas or to a bottom-side copper plane.

The maximum allowable junction temperature (T_J) determines the maximum power dissipation for the device. According to [方程式 3](#), power dissipation and junction temperature are most often related by the junction-to-ambient thermal resistance ($R_{\theta JA}$) of the combined PCB and device package and the temperature of the ambient air (T_A).

$$T_J = T_A + (R_{\theta JA} \times P_D) \quad (3)$$

[方程式 4](#) rearranges [方程式 3](#) for output current.

$$I_{OUT} = (T_J - T_A) / [R_{\theta JA} \times (V_{IN} - V_{OUT})] \quad (4)$$

Unfortunately, this thermal resistance ($R_{\theta JA}$) is highly dependent on the heat-spreading capability built into the particular PCB design, and therefore varies according to the total copper area, copper weight, and location of the planes. The $R_{\theta JA}$ recorded in the [Thermal Information](#) table is determined by the JEDEC standard, PCB, and copper-spreading area, and is only used as a relative measure of package thermal performance. For a well-designed thermal layout, $R_{\theta JA}$ is actually the sum of the package junction-to-case (bottom) thermal resistance ($R_{\theta JC(bot)}$) plus the thermal resistance contribution by the PCB copper.

7.1.6 Estimating Junction Temperature

The JEDEC standard now recommends the use of psi (Ψ) thermal metrics to estimate the junction temperatures of the LDO when in-circuit on a typical PCB board application. These metrics are not strictly speaking thermal resistances, but rather offer practical and relative means of estimating junction temperatures. These psi metrics are determined to be significantly independent of the copper-spreading area. The key thermal metrics (Ψ_{JT} and Ψ_{JB}) are used in accordance with [方程式 5](#) and are given in the [Thermal Information](#) table.

$$\Psi_{JT} : T_J = T_T + \Psi_{JT} \times P_D \text{ and } \Psi_{JB} : T_J = T_B + \Psi_{JB} \times P_D \quad (5)$$

where:

- P_D is the power dissipated as explained in the [Power Dissipation \(\$P_D\$ \)](#) section
- T_T is the temperature at the center-top of the device package
- T_B is the PCB surface temperature measured 1mm from the device package and centered on the package edge

7.1.7 Recommended Area For Continuous Operation

The operational area of an LDO is limited by the dropout voltage, output current, junction temperature, and input voltage. The recommended area for continuous operation for a linear regulator is given in [图 7-3](#) and is separated into the following parts:

- Dropout voltage limits the minimum differential voltage between the input and the output ($V_{IN} - V_{OUT}$) at a given output current level. See the [Dropout Operation](#) section for more details.
- The rated output currents limits the maximum recommended output current level. Exceeding this rating causes the device to fall out of specification.

- The rated junction temperature limits the maximum junction temperature of the device. Exceeding this rating causes the device to fall out of specification and reduces long-term reliability.
 - The shape of the slope is depicted in the third region of 图 7-3. The slope is nonlinear because the maximum-rated junction temperature of the LDO is controlled by the power dissipation across the LDO. Thus, when $V_{IN} - V_{OUT}$ increases the output current decreases.
- The rated input voltage range governs both the minimum and maximum of $V_{IN} - V_{OUT}$.

图 7-3 shows the recommended area of operation for this device on a JEDEC-standard high-K board with a $R_{\theta JA}$, as given in the [Thermal Information](#) table.

7.2 Typical Application

图 7-4 shows the typical application circuit for the TPS7A21-Q1. If necessary for some applications, increase the input and output capacitances above the 1 μ F minimum value.

图 7-4. TPS7A21-Q1 Typical Application

7.2.1 Design Requirements

表 7-1 summarizes the design requirements for the typical application circuit.

表 7-1. Design Parameters

DESIGN PARAMETER	EXAMPLE VALUE
Input voltage range	3.6V to 4.2V
Output voltage	3.3V
Output current	350mA
Maximum ambient temperature	125°C

7.2.2 Detailed Design Procedure

For this design example, the 3.3V output version (TPS7A2133PQWDRBRQ1) is selected. A nominal 3.6V input supply is assumed. Use a minimum 1.0 μ F input capacitor to minimize the effect of resistance and inductance between the source and the LDO input. Use a minimum 1.0 μ F output capacitor for stability and good load transient response. The dropout voltage (V_{DO}) is less than 150mV maximum at a 3.3V output voltage and 500mA output current, so there are no dropout issues with an input voltage of 3.6V and a maximum output current of 350mA.

7.2.2.1 Power Dissipation and Device Operation

The permissible power dissipation for any package is a measure of the capability of the device to pass heat from the power source (the junctions of the device) to the ultimate heat sink of the ambient environment. Thus, power dissipation is dependent on the ambient temperature and the thermal resistance across the various interfaces between the die junction and ambient air.

方程式 6 calculates the maximum allowable power dissipation for the device in a given package:

$$P_{D-MAX} = ((T_{J-MAX} - T_A) / R_{\theta JA}) \quad (6)$$

方程式 7 represents the actual power being dissipated in the device:

$$P_D = (V_{IN} - V_{OUT}) \times I_{OUT} \quad (7)$$

These two equations establish the relationship between the maximum power dissipation allowed resulting from thermal consideration, the voltage drop across the device, and the continuous current capability of the device. Use these two equations to determine the optimum operating conditions for the device in the application.

In applications where lower power dissipation (P_D) or excellent package thermal resistance ($R_{\theta JA}$) is present, increase the maximum ambient temperature (T_{A-MAX}).

In applications where high power dissipation or poor package thermal resistance is present, derate the maximum ambient temperature (T_{A-MAX}) if necessary. As given by 方程式 8, T_{A-MAX} is dependent on the maximum operating junction temperature ($T_{J-MAX-OP} = 150^\circ\text{C}$), the maximum allowable power dissipation in the device package in the application (P_{D-MAX}), and the junction-to ambient thermal resistance of the device or package in the application ($R_{\theta JA}$):

$$T_{A-MAX} = (T_{J-MAX-OP} - (R_{\theta JA} \times P_{D-MAX})) \quad (8)$$

Alternately, if T_{A-MAX} is unable to be derated, do not reduce the P_D value. This reduction is accomplished by reducing V_{IN} in the $V_{IN} - V_{OUT}$ term as long as the minimum V_{IN} is met, or by reducing the I_{OUT} term, or by some combination of the two.

7.2.3 Application Curves

7.3 Power Supply Recommendations

This LDO is designed to operate from an input supply voltage range of 2.0V to 5.5V. Make sure the input supply is well regulated and free of spurious noise. To make sure that the TPS7A21-Q1 output voltage is well regulated and dynamic performance is optimum, set the input supply to be at least $V_{OUT} + 0.3V$. A minimum capacitor value of 1μF is required to be within 1cm of the IN pin.

7.4 Layout

7.4.1 Layout Guidelines

The dynamic performance of the TPS7A21-Q1 is dependent on the layout of the PCB. PCB layout practices that are adequate for typical LDOs potentially degrade the PSRR, noise, or transient performance of the TPS7A21-Q1.

Best performance is achieved by placing C_{IN} and C_{OUT} on the same side of the PCB as the TPS7A21-Q1, and as close to the package as practical. Route the ground connections for C_{IN} and C_{OUT} back to the TPS7A21-Q1 ground pin using as wide and short a copper trace as practical.

Avoid connections using long trace lengths, narrow trace widths, or connections through vias. These connections add parasitic inductances and resistance that results in inferior performance, especially during transient conditions.
