7 Detailed Description

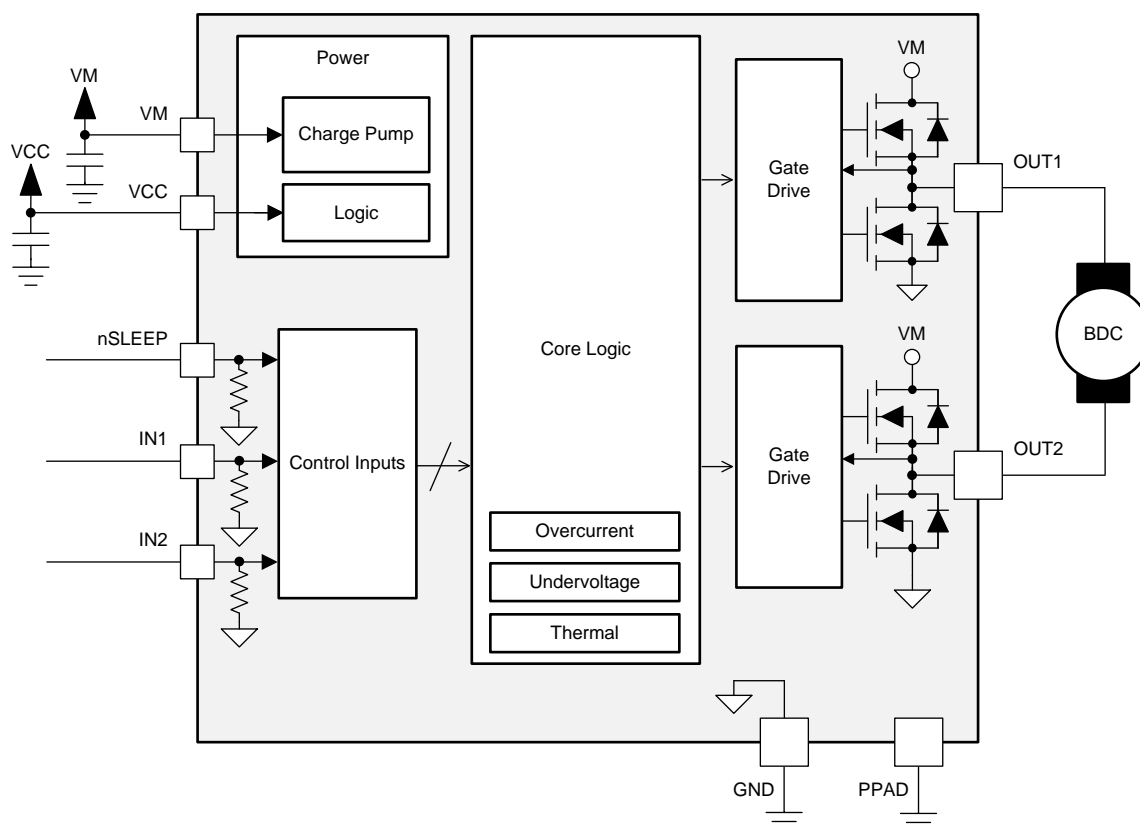

7.1 Overview

The DRV8837C device is an H-bridge driver that can drive one DC motor or other devices like solenoids. The outputs are controlled using a PWM interface (IN1/IN2).

A low-power sleep mode is included, which can be enabled using the nSLEEP pin.

This device greatly reduces the component count of motor driver systems by integrating the necessary driver FETs and FET control circuitry into a single device. In addition, the DRV8837C device adds protection features beyond traditional discrete implementations: undervoltage lockout, overcurrent protection, and thermal shutdown.

7.3 Feature Description

7.3.1 Bridge Control

The DRV8837C device is controlled using a PWM input interface, also called an IN/IN interface. Each output is controlled by a corresponding input pin.

表 1 shows the logic for the DRV8837C device.

表 1. DRV8837C Device Logic

nSLEEP	IN1	IN2	OUT1	OUT2	FUNCTION (DC MOTOR)
0	X	X	Z	Z	Coast
1	0	0	Z	Z	Coast
1	0	1	L	H	Reverse
1	1	0	H	L	Forward
1	1	1	L	L	Brake

7.3.2 Sleep Mode

If the nSLEEP pin is brought to a logic-low state, the DRV8837C device enters a low-power sleep mode. In this state, all unnecessary internal circuitry is powered down.

7.3.3 Power Supplies and Input Pins

The input pins can be driven within the recommended operating conditions with or without the VCC, VM, or both power supplies present. No leakage current path exists to the supply. Each input pin has a weak pulldown resistor (approximately 100 k Ω) to ground.

The VCC and VM supplies can be applied and removed in any order. When the VCC supply is removed, the device enters a low-power state and draws very little current from the VM supply. The VCC and VM pins can be connected together if the supply voltage is between 1.8 and 7 V.

The VM voltage supply does not have any undervoltage-lockout protection (UVLO). As long as $V_{CC} > 1.8$ V, the internal device logic remains active which means that the VM pin voltage can drop to 0 V, however, the load may not be sufficiently driven at low VM voltages.

7.3.4 Protection Circuits

The DRV8837C is fully protected against VCC undervoltage, overcurrent, and overtemperature events.

VCC undervoltage lockout If at any time the voltage on the VCC pin falls below the undervoltage lockout threshold voltage, all FETs in the H-bridge are disabled. Operation resumes when the VCC pin voltage rises above the UVLO threshold.

Overcurrent protection (OCP) An analog current-limit circuit on each FET limits the current through the FET by removing the gate drive. If this analog current limit persists for longer than t_{DEG} , all FETs in the H-bridge are disabled. Operation resumes automatically after t_{RETRY} has elapsed. Overcurrent conditions are detected on both the high-side and low-side devices. A short to the VM pin, GND, or from the OUT1 pin to the OUT2 pin results in an overcurrent condition.

Thermal shutdown (TSD) If the die temperature exceeds safe limits, all FETs in the H-bridge are disabled. After the die temperature falls to a safe level, operation automatically resumes.

表 2. Fault Behavior

FAULT	CONDITION	H-BRIDGE	RECOVERY
VCC undervoltage (UVLO)	$V_{CC} < 1.7$ V	Disabled	$V_{CC} > 1.8$ V
Overcurrent (OCP)	$I_{OUT} > 1.2$ A (MIN)	Disabled (retries automatically)	t_{RETRY} elapses
Thermal Shutdown (TSD)	$T_J > 150^{\circ}\text{C}$ (MIN)	Disabled (retries automatically)	$T_J < 150^{\circ}\text{C}$

7.4 Device Functional Modes

The DRV8837C device is active unless the nSLEEP pin is brought logic low. In sleep mode the H-bridge FETs are disabled Hi-Z. The DRV8837C device is brought out of sleep mode automatically if nSLEEP is brought logic high.

The H-bridge outputs are disabled during undervoltage lockout, overcurrent, and overtemperature fault conditions.

表 3. Operation Modes

MODE	CONDITION	H-BRIDGE
Operating	nSLEEP pin = 1	Operating
Sleep mode	nSLEEP pin = 0	Disabled
Fault encountered	Any fault condition met	Disabled (retries automatically)

8 Application and Implementation

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

8.1 Application Information

The DRV8837C device is used to drive one DC motor or other devices like solenoids. The following design procedure can be used to configure the DRV8837C device.

8.2 Typical Application

图 7. Schematic of DRV8837C Application

8.2.1 Design Requirements

表 4 lists the required parameters for a typical usage case.

表 4. System Design Requirements

DESIGN PARAMETER	REFERENCE	EXAMPLE VALUE
Motor supply voltage	VM	9 V
Logic supply voltage	VCC	3.3 V
Target RMS current	I _{OUT}	0.8 A

8.2.2 Detailed Design Procedure

8.2.2.1 Motor Voltage

The appropriate motor voltage depends on the ratings of the motor selected and the desired RPM. A higher voltage spins a brushed dc motor faster with the same PWM duty cycle applied to the power FETs. A higher voltage also increases the rate of current change through the inductive motor windings.

8.2.2.2 Low-Power Operation

When entering sleep mode, TI recommends setting all inputs as a logic low to minimize system power.

8.2.3 Application Curves

图 11. 20% Duty Cycle, Reverse Direction

9 Power Supply Recommendations

9.1 Bulk Capacitance

Having appropriate local bulk capacitance is an important factor in motor-drive system design. It is generally beneficial to have more bulk capacitance, while the disadvantages are increased cost and physical size.

The amount of local capacitance needed depends on a variety of factors, including:

- The highest current required by the motor system
- The power-supply capacitance and ability to source current
- The amount of parasitic inductance between the power supply and motor system
- The acceptable voltage ripple
- The type of motor used (brushed dc, brushless dc, stepper)
- The motor braking method

The inductance between the power supply and motor drive system limits the rate at which current can change from the power supply. If the local bulk capacitance is too small, the system responds to excessive current demands or dumps from the motor with a change in voltage. When adequate bulk capacitance is used, the motor voltage remains stable and high current can be quickly supplied.

The data sheet generally provides a recommended value, but system-level testing is required to determine the appropriate size of bulk capacitor.

Bulk Capacitance (接下页)

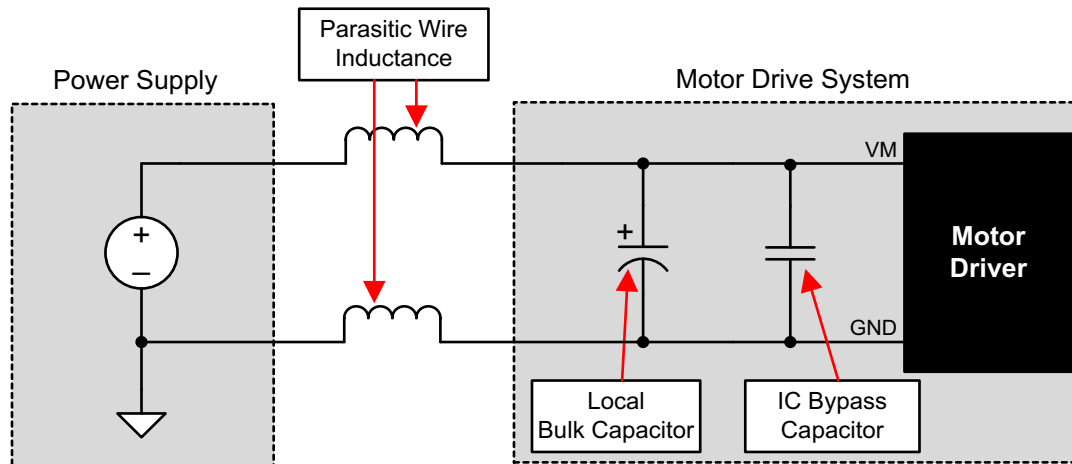

图 12. Example Setup of Motor Drive System With External Power Supply

The voltage rating for bulk capacitors should be higher than the operating voltage, to provide margin for cases when the motor transfers energy to the supply

10 Layout

10.1 Layout Guidelines

The VM and VCC pins should be bypassed to GND using low-ESR ceramic bypass capacitors with a recommended value of 0.1 μF rated for the VM and VCC supplies. These capacitors should be placed as close to the VM and VCC pins as possible with a thick trace or ground plane connection to the device GND pin. In addition bulk capacitance is required on the VM pin.

10.2 Layout Example

图 13. Simplified Layout Example

10.3 Power Dissipation

Power dissipation in the DRV8837C device is dominated by the power dissipated in the output FET resistance, or $R_{DS(ON)}$. Use 公式 1 to estimate the average power dissipation when running a brushed-DC motor.

$$P_{TOT} = R_{DS(ON)} \times (I_{OUT(RMS)})^2$$

where

- P_{TOT} is the total power dissipation
 - $R_{DS(ON)}$ is the resistance of the HS plus LS FETs
 - $I_{OUT(RMS)}$ is the RMS or DC output current being supplied to the load
- (1)

The maximum amount of power that can be dissipated in the device is dependent on ambient temperature and heatsinking.

注

The value of $R_{DS(ON)}$ increases with temperature, so as the device heats, the power dissipation increases.

The DRV8837C device has thermal shutdown protection. If the die temperature exceeds approximately 150°C, the device is disabled until the temperature drops to a safe level.

Any tendency of the device to enter thermal shutdown is an indication of either excessive power dissipation, insufficient heatsinking, or too high an ambient temperature.
