TEXAS INSTRUMENTS
LM5148
ZHCSNB4 – FEBRUARY 2023

# LM5148 80V、具有超低 $I_Q$ 和双随机展频的同步降压直流/直流控制器

## 1 特性

- 功能安全型
  - 有助于进行功能安全系统设计的文档
- 集成式 EMI 缓解
  - 可选双随机展频 (DRSS) 特性，可在低频和高频频带上增强 EMI 降低性能
  - 针对 CISPR 32 B 类要求进行了优化
- 多功能同步降压直流/直流控制器
  - 宽输入电压范围为 3.5V 至 80V
  - 1% 精度、固定 3.3V/5V/12V 或 0.8V 至 55V 可调输出电压
  - 150°C 最大结温
  - 无损 DCR 或分流电流检测
  - 关断时的静态电流为 2.3μA（典型值）
  - 9.5μA 低漏电流
  - 3ms 的内部软启动斜坡
  - 最多可堆叠两个相位
  - 内部自举二极管
- 开关频率范围为 100kHz 至 2.2MHz
  - 同步输入和同步输出功能
  - 可选 PFM 或 FPWM 模式
- 固有保护特性，可实现稳健设计
  - 内部断续模式过流保护
  - 使能和 PGOOD 功能
  - VCC、VDDA 和栅极驱动 UVLO 保护
  - 内部或外部环路补偿
  - 具有迟滞功能的热关断保护
- 使用 LM5148 并借助 WEBENCH® Power Designer 创建定制设计方案

## 2 应用

- 楼宇自动化
- 工业运输
- 电力输送
- 测试和测量
- 航天和国防

## 3 说明

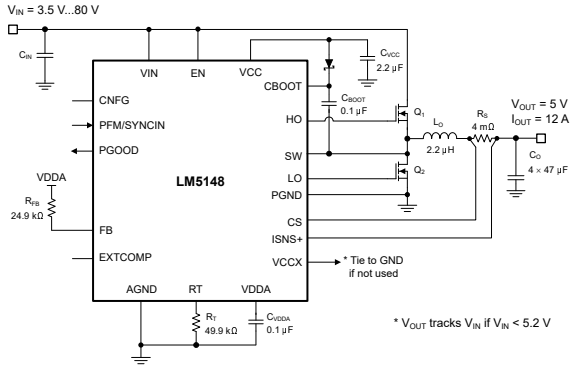

LM5148 是一款 80V 超低 $I_Q$ 同步降压直流/直流控制器，适合高电流单输出应用。该控制器使用峰值电流模式控制架构，可实现简单环路补偿、快速瞬态响应和出色的负载和线路调节性能。LM5148 可设置为以交错模式（并联输出）运行，实现精确的电流共享，适合高电流应用。它可在低至 3.5V 的输入电压和接近 100% 的占空比（如果需要）下运行。

LM5148 具有一种独特的 EMI 降低特性，称为双随机展频 (DRSS)。将低频三角调制与高频随机调制相结合，可分别在低频和高频频带上降低 EMI 干扰。此项混合技术符合业界通用的 EMC 测试中指定的多种分辨率带宽 (RBW) 设置。

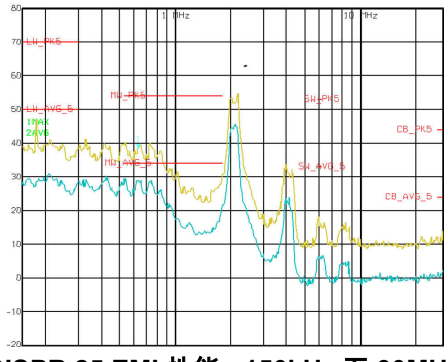

**封装信息**

| 器件型号 | 封装(1) | 封装尺寸（标称值） |
|---|---|---|
| LM5148 | RGY（VQFN，24） | 3.50mm × 5.50mm |

(1) 如需了解所有可用封装，请参阅数据表末尾的可订购产品附录

典型应用原理图

CISPR 25 EMI 性能 - 150kHz 至 30MHz

## 5 说明（续）

LM5148 的其他特性包括 150°C 最大工作结温、可在轻负载条件下降低电流消耗的用户可选二极管仿真功能、用于故障报告和输出监控的开漏电源正常标志、精密使能输入、单调启动至预偏置负载、集成 VCC 偏置电源稳压器、3ms 内部软启动时间和带自动恢复功能的热关断保护。

LM5148 控制器采用 3.5mm × 5.5mm 热增强型 24 引脚 VQFN 封装，该封装。

# 6 Pin Configuration and Functions

Connect the exposed pad to AGND and PGND on the PCB.

**图 6-1. 24-Pin VQFN RGY Package (Top View)**

**表 6-1. Pin Functions**

| PIN | | I/O[1] | DESCRIPTION |
|---|---|---|---|
| NO. | NAME | | |
| 1 | NC | – | Connect to GND at the exposed pad to improve heat spreading. |
| 2 | NC | – | Connect to GND at the exposed pad to improve heat spreading. |
| 3 | CNFG | I | Connect a resistor to ground to set primary/secondary, spread spectrum enable/disable, or interleaved operation. |
| 4 | RT | I | Frequency programming pin. A resistor from RT to AGND sets the oscillator frequency between 100 kHz and 2.2 MHz. |
| 5 | EXTCOMP | O | Transconductance error amplifier output. If used, connect the compensation network from EXTCOMP to AGND. |
| 6 | FB | I | Connect FB to VDDA to set the output voltage to 3.3 V. Connect FB using a 24.9 kΩ or 49.9 kΩ to VDDA to set the output voltage to 5 V or 12 V, respectively. Install a resistor divider from VOUT to AGND to set the output voltage setpoint between 0.8 V and 55 V. The FB regulation voltage is 0.8 V. |
| 7 | AGND | G | Analog ground connection. Ground return for the internal voltage reference and analog circuits |
| 8 | VDDA | O | Internal analog bias regulator. Connect a ceramic decoupling capacitor from VDDA to AGND. |
| 9 | VCC | P | VCC bias supply pin. Connect a ceramic capacitor between VCC and PGND. |
| 10 | PGND | G | Power ground connection pin for low-side MOSFET gate driver |
| 11 | LO | O | Low-side power MOSFET gate driver output |
| 12 | VIN | P | Supply voltage input source for the VCC regulator |
| 13 | HO | O | High-side power MOSFET gate driver output |
| 14 | SW | P | Switching node of the buck regulator and high-side gate driver return. Connect to the bootstrap capacitor, the source terminal of the high-side MOSFET, and the drain terminal of the low-side MOSFET. |
| 15 | CBOOT | P | High-side driver supply for bootstrap gate drive |
| 16 | VCCX | P | Optional input for an external bias supply. If $V_{VCCX}$ > 4.3 V, VCCX is internally connected to VCC and the internal VCC regulator is disabled. |

表 6-1. Pin Functions (continued)

| PIN | | I/O(1) | DESCRIPTION |
|---|---|---|---|
| NO. | NAME | | |
| 17 | PG/SYNCOUT | O | An open-collector output that goes low if VOUT is outside the specified regulation window. The PG/SYNCOUT pin of the primary controller in dual-phase mode provides a 180° phase-shifted SYNCOUT signal. |
| 18 | PFM/SYNC | I | Connect PFM/SYNC to VDDA to enable diode emulation mode. Connect PFM to AGND to operate the LM5148 in forced PWM (FPWM) mode with continuous conduction at light loads. PFM can also be used as a synchronization input to synchronize the internal oscillator to an external clock signal. |
| 19 | EN | I | An active-high precision input with rising threshold of 1 V and hysteresis current of 10 µA. If the EN voltage is less than 0.5 V, the LM5148 is in shutdown mode, unless a SYNC signal is present on PFM/SYNC. |
| 20 | ISNS+ | I | Current sense amplifier input. Connect this pin to the inductor side of the external current sense resistor (or to the relevant sense capacitor terminal if inductor DCR current sensing is used) using a low-current Kelvin connection. |
| 21 | VOUT | I | Output voltage sense and the current sense amplifier input. Connect VOUT to the output side of the current sense resistor (or to the relevant sense capacitor terminal if inductor DCR current sensing is used). |
| 22 | NC | — | Connect to GND at the exposed pad to improve heat spreading. |
| 23 | NC | — | Connect to GND at the exposed pad to improve heat spreading. |
| 24 | NC | — | Connect to GND at the exposed pad to improve heat spreading. |

(1) P = Power, G = Ground, I = Input, O = Output

# 7 Specifications

## 7.1 Absolute Maximum Ratings

Over the recommended operating junction temperature range of –40℃ to 150℃ (unless otherwise noted). ((1))

| | | MIN | MAX | UNIT |
|---|---|---|---|---|
| Output voltage | VOUT, ISNS+ to AGND | –0.3 | 60 | V |
| | VOUT to ISNS+ | –0.3 | 0.3 | V |
| Input voltage | VIN to PGND | –0.3 | 85 | V |
| | SW to PGND | –0.3 | 85 | V |
| | SW to PGND, transient < 20 ns | –5 | | V |
| | CBOOT to SW | –0.3 | 6.5 | V |
| | CBOOT to SW, transient < 20 ns | –2 | | V |
| | HO to SW | –0.3 | $V_{HB}$ + 0.3 | V |
| | HO to SW, transient < 20ns | –5 | | V |
| | LO to PGND | –0.3 | $V_{VCC}$ + 0.3 | V |
| | LO to PGND, transient < 20 ns | –1.5 | | V |
| | EN to PGND | –0.3 | 85 | V |
| | VCC, VCCX, VDDA, PG, FB, PFM/SYNC, RT, EXTCOMP to AGND | –0.3 | 6.5 | V |
| | CNFG to AGND | –0.3 | 5.5 | V |
| Operating junction temperature, $T_J$ | | –40 | 150 | °C |
| Storage temperature, $T_{stg}$ | | –55 | 150 | °C |

(1) Operation outside the Absolute Maximum Ratings may cause permanent device damage. Absolute Maximum Ratings do not imply functional operation of the device at these or any other conditions beyond those listed under Recommended Operating Conditions. If used outside the Recommended Operating Conditions but within the Absolute Maximum Ratings, the device may not be fully functional, and this may affect device reliability, functionality, performance, and shorten the device lifetime. .

## 7.2 ESD Ratings

| | | | VALUE | UNIT |
|---|---|---|---|---|
| $V_{(ESD)}$ | Electrostatic discharge | Human-body model (HBM), per ANSI/ESDA/JEDEC JS-001 (1) | ±2000 | V |
| | | Charged-device model (CDM), per ANSI/ESDA/JEDEC JS-002 ((2)) | ±750 | |

(1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
(2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

## 7.3 Recommended Operating Conditions

Over the operating junction temperature range of –40℃ to 150℃ (unless otherwise noted). ((1))

| | | MIN | NOM | MAX | UNIT |
|---|---|---|---|---|---|
| $V_{IN}$ | Input supply voltage range | 3.5 | | 80 | V |
| $V_{OUT}$ | Output voltage range | 0.8 | | 55 | V |
| | SW to PGND | –0.3 | | 80 | V |
| | CBOOT to SW | –0.3 | 5 | 5.25 | V |
| | FB, EXTCOMP, RT, CNFG to AGND | –0.3 | | 5.25 | V |
| | EN to PGND | –0.3 | | 80 | V |
| | VCC, VCCX, VDDA to PGND | –0.3 | 5 | 5.25 | V |
| | VOUT, ISNS+ to PGND | –0.3 | | 55 | V |
| | PGND to AGND | –0.3 | | 0.3 | V |
| | CNFG to AGND | –0.3 | | 5.5 | V |

Copyright © 2023 Texas Instruments Incorporated

Over the operating junction temperature range of –40°C to 150°C (unless otherwise noted). ((1))

| | | MIN | NOM | MAX | UNIT |
|---|---|---|---|---|---|
| $T_J$ | Operating junction temperature | –40 | | 150 | °C |

(1) Recommended operating conditions are conditions under which the device is intended to be functional. For specifications and test conditions, see the Electrical Characteristics.

## 7.4 Thermal Information

| THERMAL METRIC(1) | | RGY (VQFN) 24 PINS | UNIT |
|---|---|---|---|
| $R_{\theta JA}$ | Junction-to-ambient thermal resistance | 37.3 | °C/W |
| $R_{\theta JC(top)}$ | Junction-to-case (top) thermal resistance | 32 | °C/W |
| $R_{\theta JB}$ | Junction-to-board thermal resistance | 15.5 | °C/W |
| $\psi_{JT}$ | Junction-to-top characterization parameter | 1.2 | °C/W |
| $\psi_{JB}$ | Junction-to-board characterization parameter | 15.5 | °C/W |
| $R_{\theta JC(bot)}$ | Junction-to-case (bottom) thermal resistance | 5.6 | °C/W |

(1) For more information about traditional and new thermal metrics, see the *Semiconductor and IC Package Thermal Metrics*

## 7.5 Electrical Characteristics

$T_J$ = –40°C to 125°C. Typical values are at $T_J$ = 25°C and $V_{IN}$ = 12 V (unless otherwise noted).

| PARAMETER | | TEST CONDITIONS | MIN | TYP | MAX | UNIT |
|---|---|---|---|---|---|---|
| **SUPPLY (VIN)** | | | | | | |
| $I_{Q-VIN1}$ | VIN shutdown current | $V_{EN}$ = 0 V | | 2.3 | 3.8 | µA |
| $I_{Q-VIN2}$ | VIN standby current | Non-switching, 0.5 V ≤ $V_{EN}$ ≤ 1 V | | 124 | | µA |
| $I_{SLEEP1}$ | Sleep current, 3.3 V | 1.03 V ≤ $V_{EN}$ ≤ 80 V, $V_{VOUT}$ = 3.3 V, in regulation, no-load, not switching, $V_{PFM/SYNC}$ = VDDA | | 9.5 | 19.7 | µA |
| $I_{SLEEP2}$ | Sleep current, 5 V | 1.03 V ≤ $V_{EN}$ ≤ 80 V, $V_{VOUT}$ = 5.0 V, in regulation, no-load, not switching, $V_{PFM/SYNC}$ = VDDA | | 9.9 | 19.9 | µA |
| **ENABLE (EN)** | | | | | | |
| $V_{SDN}$ | Shutdown to standby threshold | $V_{EN}$ rising | | 0.5 | | V |
| $V_{EN-HIGH}$ | Enable voltage rising threshold | $V_{EN}$ rising, enable switching | 0.95 | 1.0 | 1.05 | V |
| $I_{EN-HYS}$ | Enable hysteresis | $V_{EN}$ = 1.1 V | –12 | –10 | –8 | µA |
| **INTERNAL LDO (VCC)** | | | | | | |
| $V_{VCC-REG}$ | VCC regulation voltage | $I_{VCC}$ = 0 mA to 100 mA | 4.7 | 5 | 5.3 | V |
| $V_{VCC-UVLO}$ | VCC UVLO rising threshold | | 3.3 | 3.4 | 3.5 | V |
| $V_{VCC-HYST}$ | VCC UVLO hysteresis | | | 148 | | mV |
| $I_{VCC-REG}$ | Internal LDO short-circuit current limit | | 115 | 170 | | mA |
| **INTERNAL LDO (VDDA)** | | | | | | |
| $V_{VDDA-REG}$ | VDDA regulation voltage | | 4.75 | 5 | 5.25 | V |
| $V_{VDDA-UVLO}$ | VDDA UVLO rising | $V_{VCC}$ rising, $V_{VCCX}$ = 0 V | 3 | 3.2 | 3.3 | V |
| $V_{VDDA-HYST}$ | VDDA UVLO hysteresis | $V_{VCCX}$ = 0 V | | 120 | | mV |
| $R_{VDDA}$ | VDDA resistance | $V_{VCCX}$ = 0 V | | 5.5 | | Ω |
| **EXTERNAL BIAS (VCCX)** | | | | | | |
| $V_{VCCX-ON}$ | VCCX rising threshold | | 4.1 | 4.3 | 4.4 | V |
| $V_{VCCX-HYST}$ | VCCX hysteresis voltage | | | 130 | | mV |
| $R_{VCCX}$ | VCCX resistance | | | 2 | | Ω |
| **REFERENCE VOLTAGE** | | | | | | |
| $V_{REF}$ | Regulated FB voltage | | 795 | 800 | 808 | mV |
| **OUTPUT VOLTAGE (VOUT)** | | | | | | |

## 7.5 Electrical Characteristics (continued)

$T_J$ = –40°C to 125°C. Typical values are at $T_J$ = 25°C and $V_{IN}$ = 12 V (unless otherwise noted).

| PARAMETER | | TEST CONDITIONS | MIN | TYP | MAX | UNIT |
|---|---|---|---|---|---|---|
| $V_{OUT-3.3V-INT}$ | 3.3-V output voltage setpoint | $R_{FB}$ = 0 Ω, $V_{IN}$ = 3.8 V to 80 V, internal compensation | 3.267 | 3.3 | 3.33 | V |
| $V_{OUT-3.3V-EXT}$ | 3.3-V output voltage setpoint | $R_{FB}$ = 0 Ω, $V_{IN}$ = 3.8 V to 80 V, external compensation | 3.267 | 3.3 | 3.33 | V |
| $V_{OUT-5V–INT}$ | 5-V output voltage setpoint | $R_{FB}$ = 24.9 kΩ, $V_{IN}$ = 5.5 V to 80 V, internal compensation | 4.95 | 5.0 | 5.05 | V |
| $V_{OUT-5V–EXT}$ | 5-V output voltage setpoint | $R_{FB}$ = 24.9 kΩ, $V_{IN}$ = 5.5 V to 80 V, external compensation | 4.95 | 5.0 | 5.05 | V |
| $V_{OUT-12V-INT}$ | 12-V output setpoint | $R_{FB}$ = 48.7 kΩ, $V_{IN}$ = 24 V to 80 V, internal compensation | 11.88 | 12 | 12.12 | V |
| $V_{OUT-12V-EXT}$ | 12-V output setpoint | $R_{FB}$ = 48.7 kΩ, $V_{IN}$ = 24 V to 80 V, external compensation | 11.88 | 12 | 12.12 | V |
| $R_{FB-OPT1}$ | 5-V output select | | 23 | 25 | 27 | kΩ |
| $R_{FB-OPT2}$ | 12-V output select | | 47 | 50 | 53 | kΩ |
| **ERROR AMPLIFIER (COMP)** | | | | | | |
| $g_{m-EXTERNAL}$ | EA transconductance, external compensation | FB to COMP | 1020 | 1200 | | µS |
| $g_{m-INTERNAL}$ | EA transconductance, internal compensation | EXTCOMP 10 kΩ to VDDA | | 30 | | µS |
| $I_{FB}$ | Error amplifier input bias current | | | | 75 | nA |
| $V_{COMP-CLAMP}$ | COMP clamp voltage | $V_{FB}$ = 0 V | | 2.1 | | V |
| $I_{COMP-SRC}$ | EA source current | $V_{EXTCOMP}$ = 1 V, $V_{FB}$ = 0.6 V | | 180 | | µA |
| $I_{COMP-SINK}$ | EA sink current | $V_{EXTCOMP}$ = 1 V, $V_{FB}$ = 1 V | | 180 | | µA |
| $R_{COMP}$ | Internal compensation | EXTCOMP 10 kΩ to VDDA | | 400 | | kΩ |
| $C_{COMP}$ | Internal compensation | EXTCOMP 10 kΩ to VDDA | | 50 | | pF |
| $C_{COMP-HF}$ | Internal compensation | EXTCOMP 10 kΩ to VDDA | | 1 | | pF |
| **PULSE FREQUENCY MODULATION (PFM/SYNC)** | | | | | | |
| $V_{PFM-LO}$ | PFM detection threshold low | | 0.8 | | | V |
| $V_{PFM-HI}$ | PFM decection threshold high | | | | 2.0 | V |
| $V_{ZC-SW}$ | Zero-cross threshold | | | –5.5 | | mV |
| $V_{ZC-DIS}$ | Zero-cross threshold disable | PFM/SYNC = 0 V, 1000 SW cycles after first HO pulse | | 100 | | mV |
| $F_{SYNCIN}$ | Frequency sync range | $R_{RT}$ = 9.52 kΩ, ±20% of the nominal oscillator frequency | 1.74 | | 2.7 | MHz |
| $t_{SYNC-MIN}$ | Minimum pulse-width of external synchronization signal | | 20 | | 250 | ns |
| $t_{SYNCIN-HO}$ | Delay from PFM faling edge to HO rising edge | | | 45 | | ns |
| $t_{PFM-FILTER}$ | SYNCIN to PFM mode | | 13 | | 45 | µs |
| **DUAL RANDOM SPREAD SPECTRUM (DRSS)** | | | | | | |
| $\Delta f_C$ | Switching frequency percentage change | | | 7 | | % |
| $f_m$ | Modulation frequency | | 8.2 | | 16.2 | kHz |
| **SWITCHING FREQUENCY** | | | | | | |
| $V_{RT}$ | RT pin regulation voltage | 10 kΩ < $R_{RT}$ < 100 kΩ | | 0.5 | | V |
| $F_{SW1}$ | Switching frequency 1 | $R_{RT}$ = 97.6 kΩ to AGND | | 0.22 | | MHz |
| $F_{SW2}$ | Switching frequency 2 | $V_{IN}$ = 12 V, $R_{RT}$ = 9.52 kΩ to AGND | 1.98 | 2.2 | 2.42 | MHz |
| $F_{SW3}$ | Switching frequency 3 | $R_{RT}$ = 220 kΩ to AGND | | 100 | | kHz |
| $SLOPE_1$ | Internal slope compensation 1 | $R_{RT}$ = 9.52 kΩ | | 600 | | mV/µs |
| $SLOPE_2$ | Internal slope compensation 2 | $R_{RT}$ = 97.6 kΩ | | 50 | | mV/µs |
| $t_{ON(min)}$ | Minimum on-time | | | 50 | | ns |
| $t_{OFF(min)}$ | Minimum off-time | | | 90 | | ns |
| **POWER GOOD (PG)** | | | | | | |

## 7.5 Electrical Characteristics (continued)

$T_J$ = –40°C to 125°C. Typical values are at $T_J$ = 25°C and $V_{IN}$ = 12 V (unless otherwise noted).

| PARAMETER | | TEST CONDITIONS | MIN | TYP | MAX | UNIT |
|---|---|---|---|---|---|---|
| $V_{PG-UV}$ | Power Good UV trip level | Falling with respect to the regulated voltage | 90% | 92% | 94% | |
| $V_{PG-OV}$ | Power Good OV trip level | Rising with respect to the regulation voltage | 108% | 110% | 112% | |
| $V_{PG-UV-HYST}$ | Power Good UV hysteresis | Rising with respect to the regulated output | | 3.6% | | |
| $V_{PG-OV-HYST}$ | Power Good OV hysteresis | Rising with respect to the regulation voltage | | 3.4% | | |
| $t_{OV-DLY}$ | OV filter time | $V_{OUT}$ rising | | 25 | | µs |
| $t_{UV-DLY}$ | UV filter time | $V_{OUT}$ falling | | 25 | | µs |
| $V_{PG-OL}$ | PG voltage | Open collector, PG/SYNC = 2 mA | | | 0.8 | V |
| **SYNCHRONIZATION OUTPUT (PG/SYNCOUT)** | | | | | | |
| $V_{SYNCOUT-LO}$ | SYNCOUT-LO low-state voltage | $R_{CNFG}$ = 54.9 kΩ or 71.5 kΩ to GND (primary), PFM/SYNC = 2 mA | | | 0.8 | V |
| $V_{SYNCOUT-HO}$ | SYNCO-HO high-state voltage | $R_{CNFG}$ = 54.9 kΩ, or 71.5 kΩ to GND (primary) PFM/SYNC = 2 mA | 2.0 | | | V |
| $t_{SYNCOUT}$ | Delay from HO rising edge to SYNCOUT (PG/SYNCOUT in primary mode) | $V_{PFM}$ = 0 V, $F_{SW}$ set by $R_{RT}$ = 97.6 kΩ | | 2.1 | | µs |
| **STARTUP (Soft Start)** | | | | | | |
| $t_{SS-INT}$ | Internal fixed soft-start time | | 1.9 | 3 | 4.6 | ms |
| **BOOT CIRCUIT** | | | | | | |
| $V_{BOOT-DROP}$ | Internal diode forward drop | $I_{CBOOT}$ = 20 mA, VCC to CBOOT | 0.63 | 0.8 | | V |
| $I_{BOOT}$ | CBOOT to SW quiescent current, not switching | $V_{EN}$ = 5 V, $V_{CBOOT-SW}$ = 5 V | 2.88 | | 4.3 | µA |
| $V_{BOOT-SW-UV-R}$ | CBOOT to SW UVLO rising threshold | $V_{CBOOT-SW}$ rising | | 2.83 | | V |
| $V_{BOOT-SW-UV-F}$ | CBOOT to SW UVLO falling threshold | $V_{CBOOT-SW}$ falling | | 2.5 | | V |
| $V_{BOOT-SW-UV-HYS}$ | CBOOT to SW UVLO hysteresis | | | 0.05 | | V |
| **HIGH-SIDE GATE DRIVER (HO)** | | | | | | |
| $V_{HO-HIGH}$ | HO high-state output voltage | $I_{HO}$ = –100 mA, $V_{HO-HIGH}$ = $V_{CBOOT}$ – $V_{HO}$ | | 106 | | mV |
| $V_{HO-LOW}$ | HO low-state output voltage | $I_{HO}$ = 100 mA | | 50 | | mV |
| $t_{HO-RISE}$ | HO rise time (10% to 90%) | $C_{LOAD}$ = 2.7 nF | | 7 | | ns |
| $t_{HO-FALL}$ | HO fall time (90% to 10%) | $C_{LOAD}$ = 2.7 nF | | 7 | | ns |
| $I_{HO-SRC}$ | HO peak source current | $V_{HO}$ = $V_{SW}$ = 0 V, $V_{CBOOT}$ = $V_{VCC}$ = 5 V | | 2.2 | | A |
| $I_{HO-SINK}$ | HO peak sink current | $V_{VCC}$ = 5 V | | 3.2 | | A |
| **LOW-SIDE GATE DRIVER (LO)** | | | | | | |
| $V_{LO-LOW}$ | LO low-state output voltage | $I_{LO}$ = 100 mA | | 50 | | mV |
| $V_{LO-HIGH}$ | LO high-state output voltage | $I_{LO}$ = –100 mA | | 130 | | mV |
| $t_{LO-RISE}$ | LO rise time (10% to 90%) | $C_{LOAD}$ = 2.7 nF | | 7 | | ns |
| $t_{LO-FALL}$ | LO fall time (90% to 10%) | $C_{LOAD}$ = 2.7 nF | | 7 | | ns |
| $I_{LO-SRC}$ | LO peak source current | $V_{LO}$ = $V_{SW}$ = 0 V, $V_{VCC}$ = 5 V | | 2.2 | | A |
| $I_{LO-SINK}$ | LO peak sink current | $V_{VCC}$ = 5 V | | 3.2 | | A |
| **ADAPTIVE DEADTIME CONTROL** | | | | | | |
| $t_{DEAD1}$ | HO off to LO on deadtime | | | 20 | | ns |

# 8 Detailed Description

## 8.1 Overview

The LM5148 is a switching DC/DC controller that features all of the functions necessary to implement a high-efficiency synchronous buck power supply operating over a wide input voltage range from 3.5 V to 80 V. The LM5148 is configured to provide a fixed 3.3-V, 5-V, or 12-V output, or an adjustable output from 0.8 V to 55 V. This easy-to-use controller integrates high-side and low-side MOSFET gate drivers capable of sourcing and sinking peak currents of 2.2 A and 3.2 A, respectively. Adaptive dead-time control is designed to minimize body diode conduction during switching transitions.

Current-mode control using a shunt resistor or inductor DCR current sensing provides inherent line feedforward, cycle-by-cycle peak current limiting, and easy loop compensation. Current-mode control using a shunt resistor or inductor DCR current sensing also supports a wide duty cycle range for high input voltage and low-dropout applications as well as when application require a high step-down conversion ratio (for example, 10-to-1). The oscillator frequency is user-programmable between 100 kHz to 2.2 MHz, and the frequency can be synchronized as high as 2.5 MHz by applying an external clock to the PFM/SYNC pin.

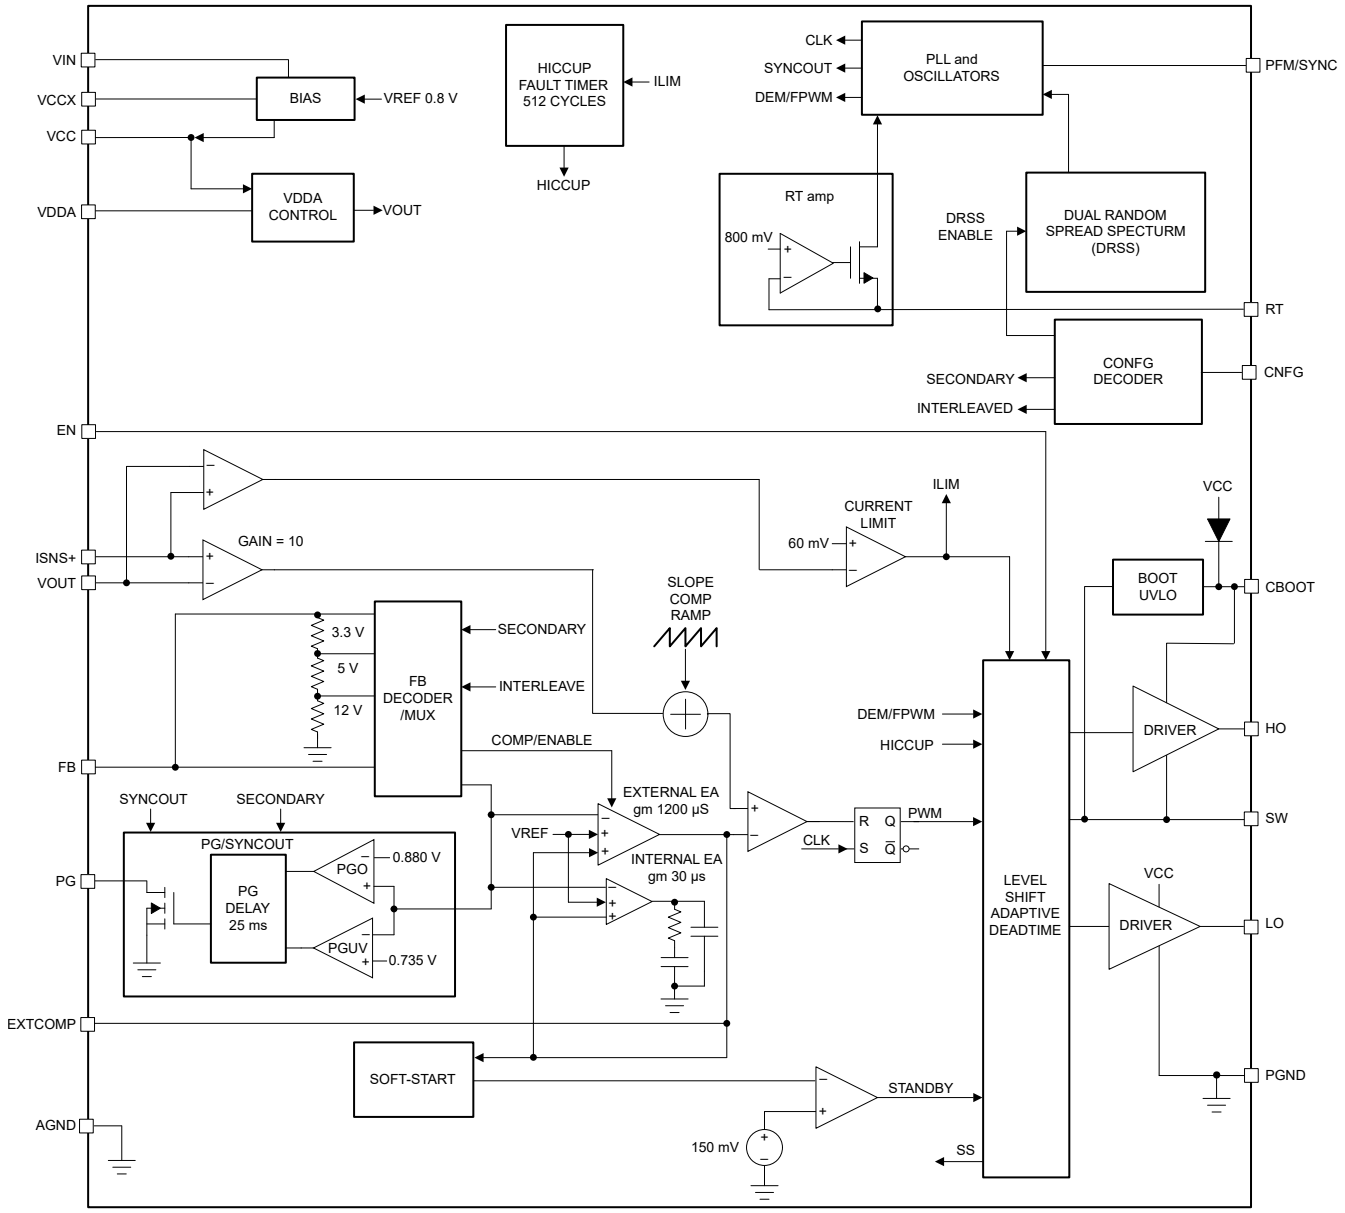

An external bias supply can be connected to VCCX to maximize efficiency in high input voltage applications. A user-selectable diode emulation feature enables discontinuous conduction mode (DCM) operation to further improve efficiency and reduce power dissipation during light-load conditions. Fault protection features include current limiting, thermal shutdown, UVLO, and remote shutdown capability.

The LM5148 incorporates features to simplify the compliance with various EMI standards, for example CISPR 11 and CISPR 32 Class B requirements. DRSS techniques reduce the peak harmonic EMI signature.

The LM5148 is provided in a 24-pin VQFN package with an exposed pad to aid in thermal dissipation.

## 8.2 Functional Block Diagram

## 8.3 Feature Description

### 8.3.1 Input Voltage Range ($V_{IN}$)

The LM5148 operational input voltage range is from 3.5 V to 80 V. The device is intended for step-down conversions from 12-V, 24-V, and 48-V supply rails. The application circuit in 图 9-4 shows all the necessary components to implement an LM5148 based wide-$V_{IN}$ single-output step-down regulator using a single supply. The LM5148 uses an internal LDO to provide a 5-V VCC bias rail for the gate drive and control circuits (assuming the input voltage is higher than 5 V with additional voltage margin necessary for the subregulator dropout specification).

In high input voltage applications, take extra care to ensure that the VIN and SW pins do not exceed their absolute maximum voltage rating of 85 V during line or load transient events. Voltage excursions that exceed the applicable voltage specifications can damage the device.

Care must be taken in applications where there are fast input transients that cause the voltage at VIN to suddenly drop more than 2 V below the VOUT setpoint. The LM5148 has an internal ESD diode from the VOUT to the VIN pins that can conduct under such conditions causing the output to discharge. To prevent damage to the internal ESD diode under the said conditions, TI recommends adding a Schottky diode in series with the VIN pin of the LM5148 to prevent reverse current flow from VOUT to VIN.

As $V_{IN}$ approaches $V_{OUT}$, the LM5148 skips $t_{OFF}$ cycles to allow the controller to extend its duty cycle up to approximately 99%. Refer to Dropout Mode.

Use 方程式 1 to calculate when the LM5148 enters dropout mode.

$$V_{IN} = V_{OUT} \times \left( \frac{t_P}{t_P - t_{OFF}} \right) \quad (1)$$

- $t_P$ is the oscillator period
- $t_{OFF}$ is the minimum off time, typical 90 ns

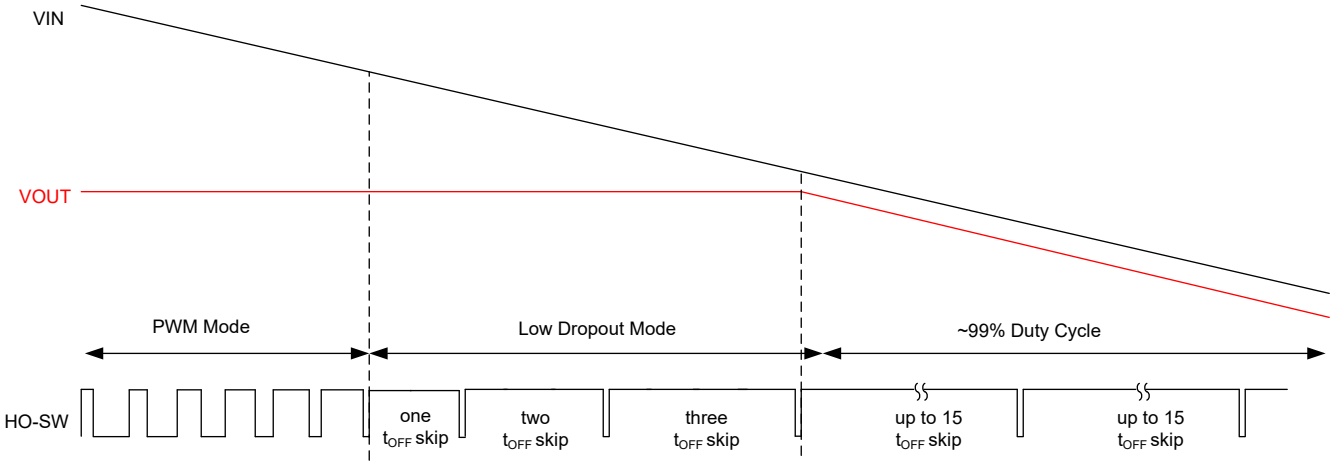

**图 8-1. Dropout Mode Operation**

### 8.3.2 High-Voltage Bias Supply Regulator (VCC, VCCX, VDDA)

The LM5148 contains an internal high-voltage VCC bias regulator that provides the bias supply for the PWM controller and the gate drivers for the external MOSFETs. The input voltage pin (VIN) can be connected directly to an input voltage source up to 80 V. However, when the input voltage is below the VCC setpoint level, the VCC voltage tracks $V_{IN}$ minus a small voltage drop.

The VCC regulator output current limit is 115 mA (minimum). At power up, the controller sources current into the capacitor connected at the VCC pin. When the VCC voltage exceeds 3.3 V and the EN pin is connected to a voltage greater than 1 V, the soft-start sequence begins. The output remains active unless the VCC voltage falls

Copyright © 2023 Texas Instruments Incorporated

below the VCC UVLO falling threshold of 3.1 V (typical) or EN is switched to a low state. Connect a ceramic capacitor from VCC to PGND. The recommended range of the VCC capacitor is from 2.2 µF to 10 µF.

An internal 5-V linear regulator generates the VDDA bias supply. Bypass VDDA with a 100-nF or higher ceramic capacitor to achieve a low-noise internal bias rail. Normally, VDDA is 5 V. However, there is one condition where VDDA regulates at 3.3 V. This is in PFM mode with a light or no-load on the output.

Minimize the internal power dissipation of the VCC regulator by connecting VCCX to a 5-V output or to an external 5-V supply. If the VCCX voltage is above 4.3 V, VCCX is internally connected to VCC and the internal VCC regulator is disabled. Tie VCCX to PGND if it is unused. Never connect VCCX to a voltage greater than 6.5 V. If an external supply is connected to VCCX to power the LM5148, $V_{IN}$ must be greater than the external bias voltage during all conditions to avoid damage to the controller.

### 8.3.3 Precision Enable (EN)

The EN pin can be connected to a voltage as high as 80 V. The LM5148 has a precision enable. When the EN voltage is greater than 1 V, controller switching is enabled. If the EN pin is pulled below 0.5 V, the LM5148 is in shutdown with an $I_Q$ of 2.3 µA (typical) current consumption from $V_{IN}$. When the enable voltage is between 0.5 V and 1 V, the LM5148 is in standby mode with the VCC regulator active but the controller is not switching. In standby mode, the non-switching input quiescent current is 124-µA typical. The LM5148 is enabled with a voltage greater than 1.0 V. However, many applications benefit from using a resistor divider $R_{UV1}$ and $R_{UV2}$, as shown in 图 8-2, to establish a precision UVLO level. TI does not recommend leaving the EN pin floating.

Use 方程式 2 and 方程式 3 to calculate the UVLO resistors given the required input turn-on and turn-off voltages.

$$R_{UV1} = \frac{V_{IN(on)} - V_{IN(off)}}{I_{HYS}} \quad (2)$$

$$R_{UV2} = R_{UV1} \cdot \frac{V_{EN}}{V_{IN(on)} - V_{EN}} \quad (3)$$

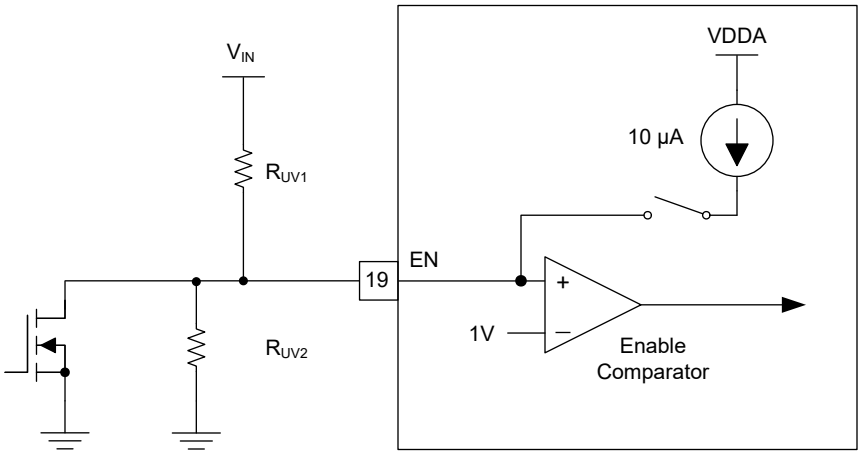

**图 8-2. Programmable Input Voltage UVLO Turn-On**

### 8.3.4 Power-Good Monitor (PG)

The LM5148 includes an output voltage monitoring signal for $V_{OUT}$ to simplify sequencing and supervision. The power-good signal is used for start-up sequencing of downstream converters, fault protection, and output monitoring. The power-good output (PG) switches to a high impedance open-drain state when the output voltage is in regulation. The PG switches low when the output voltage drops below the lower power-good threshold (92% typical) or rises above the upper power-good threshold (110% typical). A 25-µs deglitch filter prevents false tripping of the power-good signal during transients. TI recommends a pullup resistor of 100 kΩ (typical) from PG to the relevant logic rail. PG is asserted low during soft start and when the buck regulator is disabled.

Copyright © 2023 Texas Instruments Incorporated

When the LM5148 is configured as a primary controller, the PG/SYNC pin becomes a synchronization clock output for the secondary controller. The synchronization signal is 180° out-of-phase with the primary HO driver output.

### 8.3.5 Switching Frequency (RT)

Program the LM5148 oscillator with a resistor from RT to AGND to set an oscillator frequency from 100 kHz and 2.2 MHz. Calculate the RT resistance for a given switching frequency using 方程式 4.

$$R_T(k\Omega) = \frac{\frac{10^6}{F_{SW}(kHz)} - 53}{45} \tag{4}$$

Under low $V_{IN}$ conditions when the on time of the high-side MOSFET exceeds the programmed oscillator period, the LM5148 extends the switching period until the PWM latch is reset by the current sense ramp exceeding the controller compensation voltage.

The approximate input voltage level at which this occurs is given by 方程式 5.

$$V_{IN(min)} = V_{OUT} \cdot \frac{t_{SW}}{t_{SW} - t_{OFF(min)}} \tag{5}$$

where

- $t_{SW}$ is the switching period.
- $t_{OFF(min)}$ is the minimum off time of 90 ns.

### 8.3.6 Dual Random Spread Spectrum (DRSS)

The LM5148 provides a digital spread spectrum, which reduces the EMI of the power supply over a wide frequency range. DRSS combines a low-frequency triangular modulation profile with a high frequency cycle-by-cycle random modulation profile. The low-frequency triangular modulation improves performance in lower radio-frequency bands, while the high-frequency random modulation improves performance in higher radio frequency bands.

Spread spectrum works by converting a narrowband signal into a wideband signal that spreads the energy over multiple frequencies. Because industry standards require different EMI receiver resolution bandwidth (RBW) settings for different frequency bands, the RBW has an impact on the spread spectrum performance. DRSS is able to simultaneously improve the EMI performance in the low and high RBWs using its low-frequency triangular modulation profile and at high frequency cycle-by-cycle random modulation, respectively. DRSS can reduce conducted emissions up to 15 dBµV in the low-frequency band (150 kHz to 30 MHz) and 5 dBµV in the high-frequency band (30 MHz to 108 MHz).

To enable DRSS, connect either a 41.2-kΩ or 71.5-kΩ resistor from CNFG to AGND. DRSS is disabled when an external clock is applied to the PFM/SYNC pin.

Copyright © 2023 Texas Instruments Incorporated

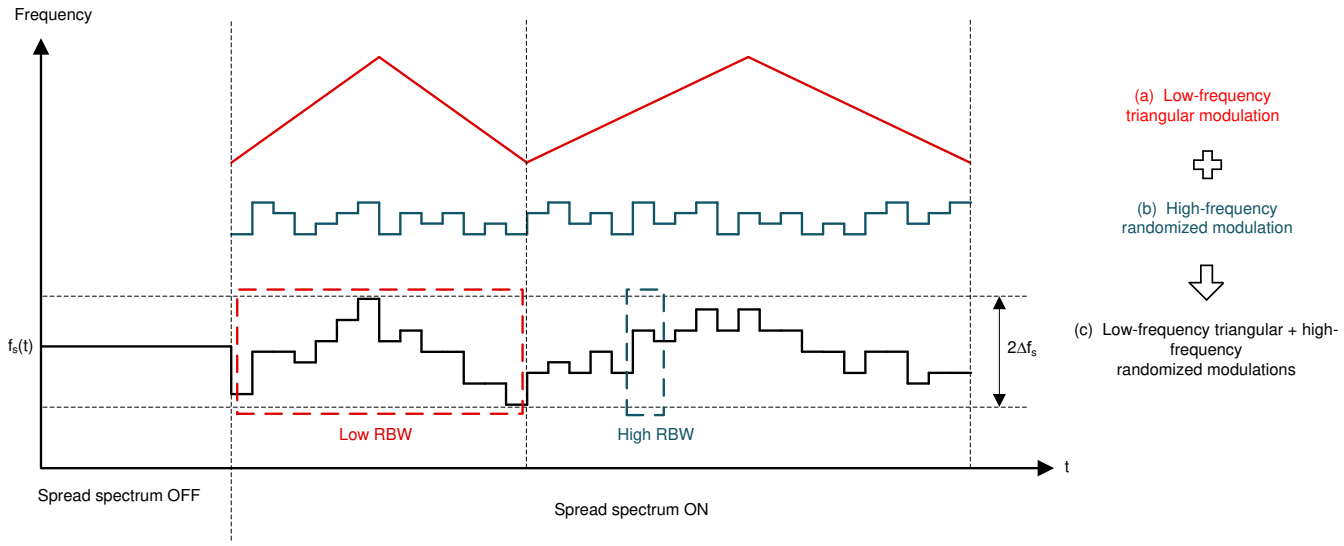

**图 8-3. Dual Random Spread Spectrum Implementation**

### 8.3.7 Soft Start

The LM5148 has an internal 3-ms soft-start timer (typical). The soft-start feature allows the regulator to gradually reach the steady-state operating point, thus reducing start-up stresses and surges.

### 8.3.8 Output Voltage Setpoint (FB)

The LM5148 output can be independently configured for one of three fixed output voltages without external feedback resistors, or adjusted to a desired voltage using an external resistor divider. Set the output to 3.3 V by connecting FB directly to VDDA. Alternatively, set the output to either 5 V or 12 V by installing a 24.9-kΩ or 49.9-kΩ resistor between FB and VDDA, respectively. See 表 8-1.

Copyright © 2023 Texas Instruments Incorporated

表 8-1. Feedback Configuration Resistors

| PULLUP RESISTOR TO VDDA | $V_{OUT}$ SETPOINT |
|---|---|
| 0 Ω | 3.3 V |
| 24.9 kΩ | 5 V |
| 49.9 kΩ | 12 V |
| Not installed | External FB divider setting |

The configuration settings are latched and cannot be changed until the LM5148 is powered down (with the VCC voltage decreasing below its falling UVLO threshold) and then powered up again (VCC rises above 3.4-V typical). Alternatively, set the output voltage with an external resistor divider from the output to AGND. The output voltage adjustment range is between 0.8 V and 55 V. The regulation voltage at FB is 0.8 V ($V_{REF}$). Use 方程式 6 to calculate the upper and lower feedback resistors, designated as $R_{FB1}$ and $R_{FB2}$, respectively.

$$R_{FB1} = \left( \frac{V_{OUT}}{V_{REF}} - 1 \right) \cdot R_{FB2} \tag{6}$$

The recommended starting value for $R_{FB2}$ is between 10 kΩ and 20 kΩ.

If low-$I_Q$ operation is required, take care when selecting the external feedback resistors. The current consumption of the external divider adds to the LM5148 sleep current (9.5 µA typical). The divider current reflected to $V_{IN}$ is scaled by the ratio of $V_{OUT}$ / $V_{IN}$.

### 8.3.9 Minimum Controllable On Time

There are two limitations to the minimum output voltage adjustment range: the LM5148 voltage reference of 0.8 V and the minimum controllable switch-node pulse width, $t_{ON(min)}$.

$t_{ON(min)}$ effectively limits the voltage step-down conversion ratio $V_{OUT}$ / $V_{IN}$ at a given switching frequency. For fixed-frequency PWM operation, the voltage conversion ratio must satisfy 方程式 7.

$$\frac{V_{OUT}}{V_{IN}} > t_{ON(min)} \cdot F_{SW} \tag{7}$$

where

- $t_{ON(min)}$ is 50 ns (typical).
- $F_{SW}$ is the switching frequency.

If the desired voltage conversion ratio does not meet the above condition, the LM5148 transitions from fixed switching frequency operation to a pulse-skipping mode to maintain output voltage regulation. For example, if the desired output voltage is 5 V with an input voltage of 24 V and switching frequency of 2.1 MHz, use 方程式 8 to check the conversion ratio.

$$\frac{5\,V}{24\,V} > 50\,ns \cdot 2.1\,MHz$$

$$0.208 > 0.105 \tag{8}$$

For wide $V_{IN}$ applications and low output voltages, an alternative is to reduce the LM5148 switching frequency to meet the requirement of 方程式 7.

### 8.3.10 Error Amplifier and PWM Comparator (FB, EXTCOMP)

The LM5148 has a high-gain transconductance amplifier that generates an error current proportional to the difference between the feedback voltage and an internal precision reference (0.8 V). The control loop

Copyright © 2023 Texas Instruments Incorporated

compensation is configured two ways. The first is using the internal compensation amplifier, which has a transconductance of 30 µS. Internal compensation is configured by connecting the EXTCOMP pin through a 10-kΩ resistance to VDDA. If a 10-kΩ resistor is not detected, the LM5148 defaults to the external loop compensation network. The transconductance of the amplifier for external compensation is 1200 µS. This is latched and cannot be reconfigured after programmed unless power to the device is recycled. Use an external compensation network if higher performance is required to meet a stringent transient response specification. To reconfigure the compensation (internal or external), remove power and allow VCC to drop below its $VCC_{UVLO}$ threshold, which is 3.3 V (typical).

TI generally recommends a type-II compensation network for peak current-mode control.

### 8.3.11 Slope Compensation

The LM5148 provides internal slope compensation for stable operation with peak current-mode control and a duty cycle greater than 50%. Calculate the buck inductance to provide a slope compensation contribution equal to one times the inductor downslope using 方程式 9.

$$L_{O\text{-}IDEAL}(\mu H) = \frac{V_{OUT}(V) \cdot R_S(m\Omega)}{24 \cdot F_{SW}(MHz)} \tag{9}$$

- A lower inductance value generally increases the peak-to-peak inductor current, which minimizes size and cost, and improves transient response at the cost of reduced light-load efficiency due to higher cores losses and peak currents.
- A higher inductance value generally decreases the peak-to-peak inductor current, reducing switch peak and RMS currents at the cost of requiring larger output capacitors to meet load-transient specifications.

### 8.3.12 Inductor Current Sense (ISNS+, VOUT)

There are two methods to sense the inductor current of the buck power stage. The first uses a current sense resistor (also known as a shunt) in series with the inductor, and the second avails of the DC resistance of the inductor (DCR current sensing).

#### *8.3.12.1 Shunt Current Sensing*

图 8-4 illustrates inductor current sensing using a shunt resistor. This configuration continuously monitors the inductor current to provide accurate overcurrent protection across the operating temperature range. For optimal current sense accuracy and overcurrent protection, use a *low inductance* ±1% tolerance shunt resistor between the inductor and the output, with a Kelvin connection to the LM5148 current sense amplifier.

If the peak voltage signal sensed from ISNS+ to VOUT exceeds the current limit threshold of 60 mV, the current limit comparator immediately terminates the HO output for cycle-by-cycle current limiting. Calculate the shunt resistance using 方程式 10.

$$R_S = \frac{V_{CS\text{-}TH}}{I_{OUT(CL)} + \frac{\Delta I_L}{2}} \tag{10}$$

where

- $V_{CS\text{-}TH}$ is current sense threshold of 60 mV.
- $I_{OUT(CL)}$ is the overcurrent setpoint that is set higher than the maximum load current to avoid tripping the overcurrent comparator during load transients.
- $\Delta I_L$ is the peak-to-peak inductor ripple current.

Copyright © 2023 Texas Instruments Incorporated

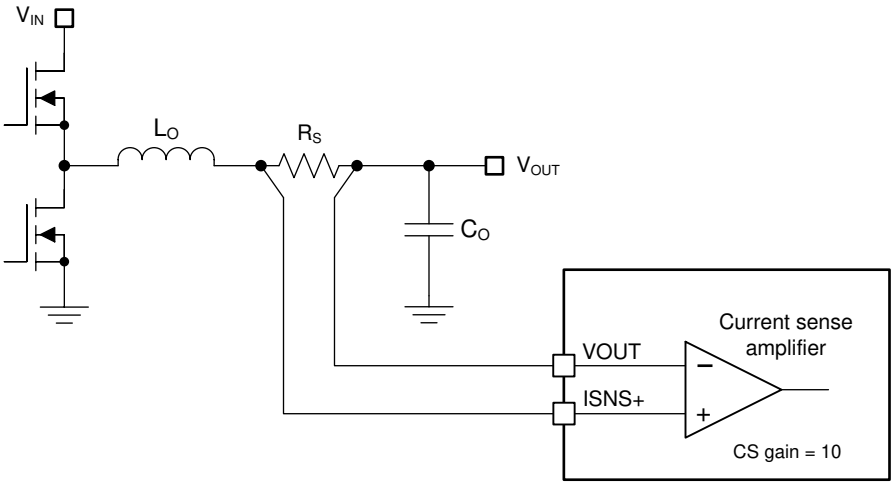

**图 8-4. Shunt Current Sensing Implementation**

The soft-start voltage is clamped 150 mV above FB during an overcurrent condition. Sixteen overcurrent events must occur before the SS clamp is enabled. This ensures that SS can be pulled low during brief overcurrent events, preventing output voltage overshoot during recovery.

### *8.3.12.2 Inductor DCR Current Sensing*

For high-power applications that do not require accurate current-limit protection, inductor DCR current sensing is preferable. This technique provides lossless and continuous monitoring of the inductor current using an RC sense network in parallel with the inductor. Select an inductor with a low DCR tolerance to achieve a typical current limit accuracy within the range of 10% to 15% at room temperature. Components $R_{CS}$ and $C_{CS}$ in 图 8-5 create a low-pass filter across the inductor to enable differential sensing of the voltage across the inductor DCR.

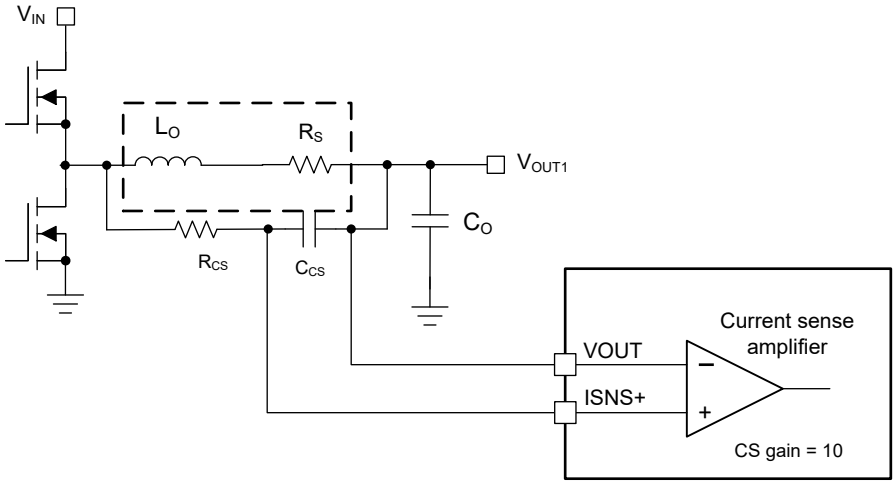

**图 8-5. Inductor DCR Current Sensing Implementation**

The voltage drop across the sense capacitor in the s-domain is given by 方程式 11. When the $R_{CS}C_{CS}$ time constant is equal to $L_O/R_{DCR}$, the voltage developed across the sense capacitor, $C_{CS}$, is a replica of the inductor DCR voltage and accurate current sensing is achieved. If the $R_{CS}C_{CS}$ time constant is not equal to the $L_O/R_{DCR}$ time constant, there is a sensing error as follows:

- $R_{CS}C_{CS} > L_O/R_{DCR}$ → the DC level is correct, but the AC amplitude is attenuated.
- $R_{CS}C_{CS} < L_O/R_{DCR}$ → the DC level is correct, but the AC amplitude is amplified.

Copyright © 2023 Texas Instruments Incorporated

$$V_{CS}(s) = \frac{1 + s \cdot \frac{L_O}{R_{DCR}}}{1 + s \cdot R_{CS} \cdot C_{CS}} \cdot R_{DCR} \cdot \left( I_{OUT(CL)} + \frac{\Delta I_L}{2} \right) \quad (11)$$

Choose the $C_{CS}$ capacitance greater than or equal to 0.1 µF to maintain a low-impedance sensing network, thus reducing the susceptibility of noise pickup from the switch node. Carefully observe 节 9.4.1 to make sure that noise and DC errors do not corrupt the current sense signals applied between the ISNS+ and VOUT pins.

### 8.3.13 Hiccup Mode Current Limiting

The LM5148 includes an internal hiccup-mode protection function. After an overload is detected, 512 cycles of cycle-by-cycle current limiting occurs. The 512-cycle counter is reset if four consecutive switching cycles occur without exceeding the current limit threshold. After the 512-cycle counter has expired, the internal soft start is pulled low, the HO and LO driver outputs are disabled, and the 16384 counter is enabled. After the counter reaches 16384, the internal soft start is enabled and the output restarts. The hiccup-mode current limit is disabled during soft start until the FB voltage exceeds 0.4 V.

### 8.3.14 High-Side and Low-Side Gate Drivers (HO, LO)

The LM5148 contains gate drivers and an associated high-side level shifter to drive the external N-channel power MOSFETs. The high-side gate driver works in conjunction with an internal bootstrap diode $D_{BOOT}$ and bootstrap capacitor $C_{BOOT}$. During the conduction interval of the low-side MOSFET, the SW voltage is approximately 0 V and CBOOT charges from VCC through the internal $D_{BOOT}$. TI recommends a 0.1-µF ceramic capacitor connected with short traces between the CBOOT and SW pins.

The LO and HO outputs are controlled with an adaptive dead-time methodology so that both outputs (HO and LO) are never on at the same time, preventing cross conduction. Before the LO driver output is allowed to turn on, the adaptive dead-time logic first disables HO and waits for the HO voltage to drop below 2 V typical. LO is allowed to turn on after a small delay (HO fall to LO rising delay). Similarly, the HO turn-on is delayed until the LO voltage has dropped below 2 V. This technique ensures adequate dead-time for any size N-channel power MOSFET implementations, including parallel MOSFET configurations.

Caution is advised when adding series gate resistors, as this can impact the effective dead-time. The selected high-side MOSFET determines the appropriate bootstrap capacitance value $C_{BOOT}$ in accordance with 方程式 12.

$$C_{BOOT} = \frac{Q_G}{\Delta V_{CBOOT}} \quad (12)$$

where

- $Q_G$ is the total gate charge of the high-side MOSFET at the applicable gate drive voltage.
- $\Delta V_{CBOOT}$ is the voltage variation of the high-side MOSFET driver after turn-on.

To determine $C_{BOOT}$, choose $\Delta V_{CBOOT}$ such that the available gate drive voltage is not significantly impacted. An acceptable range of $\Delta V_{CBOOT}$ is 100 mV to 300 mV. The bootstrap capacitor must be a low-ESR ceramic capacitor, typically 0.1 µF. Use high-side and low-side MOSFETs with logic-level gate threshold voltages.

### 8.3.15 Output Configurations (CNFG)

The LM5148 can be configured as a primary controller (interleaved mode) or as a secondary controller for paralleling the outputs for high-current applications with a resistor $R_{CNFG}$. This resistor also configures if spread spectrum is enabled or disabled. See 表 8-2. After the VCC voltage is above 3.3 V (typical), the CNFG pin voltage is monitored and latched. To change the configuration mode, the LM5148 must be powered down, and VCC must drop below 3.3 V. 图 8-6 shows the configuration timing diagram.

When the LM5148 is configured as a primary controller with spread spectrum enabled ($R_{CNFG}$ of 41.2 kΩ or 71.5 kΩ), the LM5148 cannot be synchronized to an external clock.

Copyright © 2023 Texas Instruments Incorporated

表 8-2. Configuration Modes

| $R_{CNFG}$ | PRIMARY/ SECONDARY | SPREAD SPECTRUM | DUAL PHASE |
|---|---|---|---|
| 29.9 kΩ | Primary | OFF | Disabled |
| 41.2 kΩ | Primary | ON | Disabled |
| 54.9 kΩ | Primary | OFF | Enabled |
| 71.5 kΩ | Primary | ON | Enabled |
| 90.9 kΩ | Secondary | N/A | Enabled |

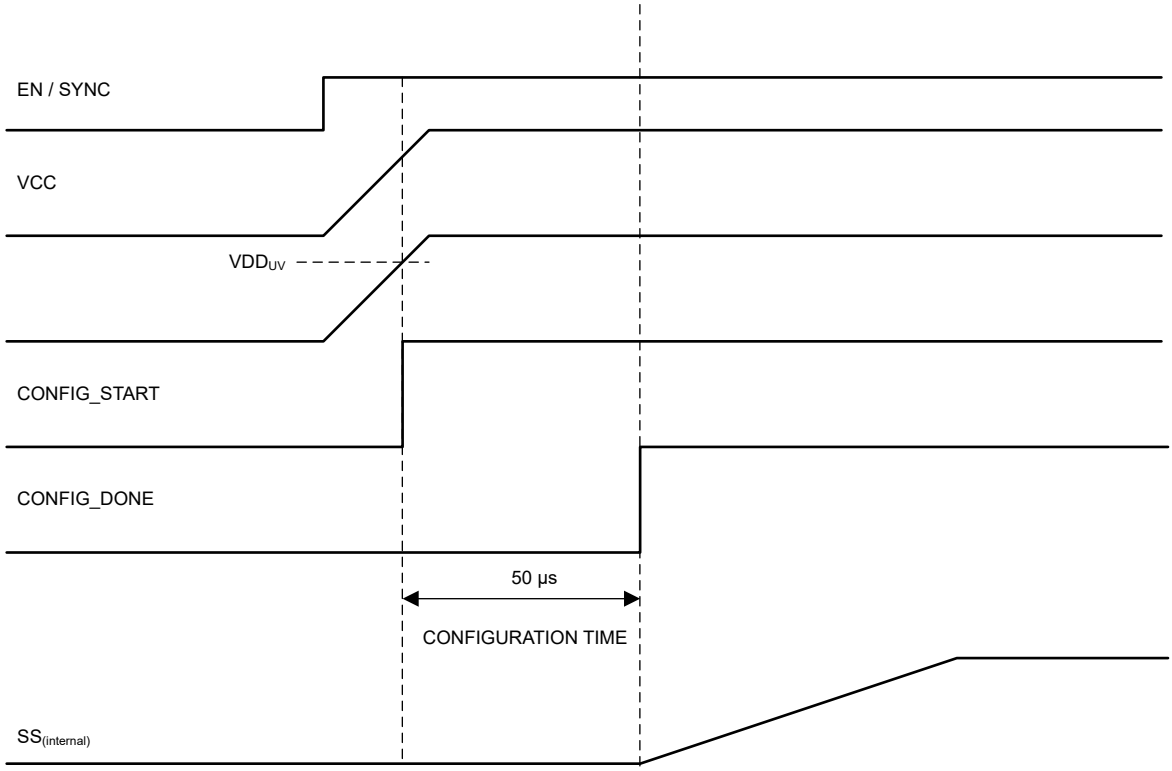

图 8-6. Configuration Timing

### 8.3.16 Single-Output Dual-Phase Operation

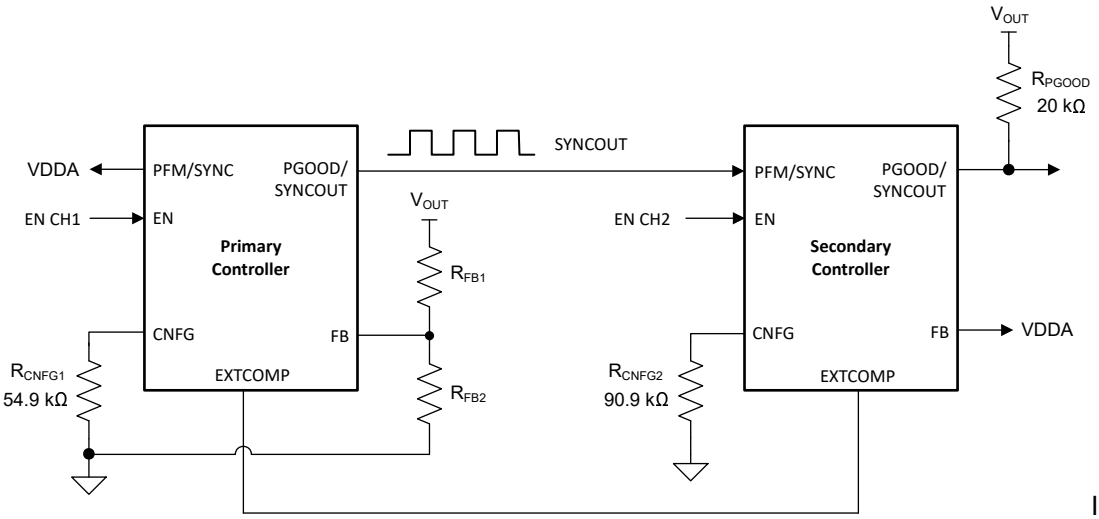

To configure for dual-phase operation, two LM5148 controllers are required. The LM5148 can only be configured in a single or dual-phase configuration where both outputs are tied together. Additional phases cannot be added. Refer to 图 8-7. Configure the first controller (CNTRL1) as a primary controller and the second controller (CNTRL2) as a secondary. To configure CNTRL1 as a primary controller, install a 54-kΩ or a 71.5-kΩ resistor from CNFG to AGND. To configure the CNTRL2 as a secondary controller, install a 90.9-kΩ resistor from CNFG to AGND. This disables the error amplifier of CNTRL2, placing it into a high-impedance state. Connect the EXTCOMP pins of the primary and secondary controllers together. The internal compensation amplifier feature is not supported when the controller is in dual-phase mode.

In dual-phase mode, the PG/SYNC pin of the primary controller becomes a SYNCOUT. Refer to *Electrical Characteristics* for voltage levels. Connect PG of the primary to PFM/SYNC (SYNCIN) of the secondary controller. The PG/SYNCOUT signal of the primary controller is 180° out-of-phase and facilitates interleaved operation. RT is not used for the oscillator when the LM5148 is in Secondary Controller mode, but instead is used for slope compensation. Therefore, select the RT resistance to be the same as that of the primary controller. The oscillator is derived from the primary controller. When in primary/secondary mode, enable both controllers simultaneously for start-up. After the regulator has started, pull the secondary EN pin low (< 0.8 V) for phase shedding if needed at light load to increase the efficiency.

Copyright © 2023 Texas Instruments Incorporated

Configure PFM mode by connecting the PFM/SYNC of the primary to VDDA and the FB of the secondary to VDDA as shown in 图 8-7. Configure FPWM mode by connecting PFM/SYNC of the primary and FB of the secondary both to AGND. An external synchronization signal can be applied to the primary PFM/SYNC (SYNCIN), and the secondary FB must be configured for FPWM. If an external SYNCIN signal is applied after start-up while in primary/secondary mode, there is a two-clock cycle delay before the LM5148 locks on to the external synchronization signal.

**图 8-7. Schematic Configured for Single-Output Dual-Phase Operation**

In PFM mode, the controller enters pulse skipping to reduce the $I_Q$ current and improve the light-load efficiency. When this occurs, the primary controller disables its synchronization clock output, so phase shedding is not supported. In PFM mode connect the two enable pins together. Phase shedding is supported in FPWM only. In FPWM, enable or disable the secondary controller as needed to support higher load current or better light-load efficiency, respectively. When the secondary controller is disabled and then re-enabled, its internal soft start is pulled low and the LM5148 goes through a normal soft-start turn-on.

When the LM5148 is configured for a single-output dual-phase operation using the internal 3.3-V feedback resistor divider, the internal bootstrap UV circuit can source current out of the SW pin, charging up the output capacitors approximately to 3.6 V. If this behavior is undesirable, you can add a 100-kΩ resistor from VOUT to GND to bleed off the charge on the output capacitors.

For more information, see the *Benefits of a Multiphase Buck Converter Technical Brief* and *Multiphase Buck Design From Start to Finish Application Report*.

## 8.4 Device Functional Modes

### 8.4.1 Sleep Mode

The LM5148 operates with peak current-mode control such that the compensation voltage is proportional to the peak inductor current. During no-load or light-load conditions, the output capacitor discharges very slowly. As a result, the compensation voltage does not demand the driver output pulses on a cycle-by-cycle basis. When the LM5148 controller detects 16 missed switching cycles, it enters sleep mode and switches to a low $I_Q$ state to reduce the current drawn from the input. For the LM5148 to go into sleep mode, the controller must be programmed for diode emulation (tie PFM/SYNC to VDDA).

The typical controller $I_Q$ in sleep mode is 9.5 µA with a 3.3-V output.

### 8.4.2 Pulse Frequency Modulation and Synchronization (PFM/SYNC)

A synchronous buck regulator implemented with a low-side synchronous MOSFET rather than a diode has the capability to sink negative current from the output during conditions of, light-load, output overvoltage, and pre-bias start-up conditions. The LM5148 provides a diode emulation feature that can be enabled to prevent reverse (drain-to-source) current flow in the low-side MOSFET. When configured for Diode Emulation mode, the low-side MOSFET is switched off when reverse current flow is detected by sensing the SW voltage using a zero-cross comparator. The benefit of this configuration is lower power loss during light-load conditions. The disadvantage of diode emulation mode is slower light-load transient response.

The PFM/SYNC pin configures diode emulation. To enable diode emulation and thus achieve low-$I_Q$ current at light loads, connect PFM/SYNC to VDDA. If FPWM with continuous conduction mode (CCM) operation is desired, tie PFM/SYNC to AGND. Note that diode emulation is automatically engaged to prevent reverse current flow during a prebias start-up. A gradual change from DCM to CCM operation provides monotonic start-up performance.

To synchronize the LM5148 to an external source, apply a logic-level clock to the PFM/SYNC pin. The LM5148 can be synchronized to ±20% of the programmed frequency up to a maximum of 2.5 MHz. If there is an RT resistor and a synchronization signal, the LM5148 ignores the RT resistor and synchronizes to the external clock. Under low $V_{IN}$ conditions when the minimum off time is reached, the synchronization signal is ignored, allowing the switching frequency to reduce to maintain output voltage regulation.

### 8.4.3 Thermal Shutdown

The LM5148 includes an internal junction temperature monitor. If the temperature exceeds 175°C (typical), thermal shutdown occurs. When entering thermal shutdown, the device:

1. Turns off the high-side and low-side MOSFETs.
2. PG/SYNCOUT switches low.
3. Turns off the VCC regulator.
4. Initiates a soft-start sequence when the die temperature decreases by the thermal shutdown hysteresis of 15°C (typical).

This is a non-latching protection, and, as such, the device cycles into and out of thermal shutdown if the fault persists.

# 9 Application and Implementation

**备注**

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes, as well as validating and testing their design implementation to confirm system functionality.

## 9.1 Application Information

### 9.1.1 Power Train Components

A comprehensive understanding of the buck regulator power train components is critical to successfully completing a synchronous buck regulator design. The following sections discuss the output inductor, input and output capacitors, power MOSFETs, and EMI input filter.

#### *9.1.1.1 Buck Inductor*

For most applications, choose a buck inductance such that the inductor ripple current, $\Delta I_L$, is between 30% to 50% of the maximum DC output current at nominal input voltage. Choose the inductance using 方程式 13 based on a peak inductor current given by 方程式 14.

$$L_O = \frac{V_{OUT}}{\Delta I_L \cdot F_{SW}} \cdot \left(1 - \frac{V_{OUT}}{V_{IN}}\right) \tag{13}$$

$$I_{L(peak)} = I_{OUT} + \frac{\Delta I_L}{2} \tag{14}$$

Check the inductor data sheet to make sure that the saturation current of the inductor is well above the peak inductor current of a particular design. Ferrite designs have very low core loss and are preferred at high switching frequencies, so design goals can then concentrate on copper loss and preventing saturation. Low inductor core loss is evidenced by reduced no-load input current and higher light-load efficiency. However, ferrite core materials exhibit a hard saturation characteristic and the inductance collapses abruptly when the saturation current is exceeded. This results in an abrupt increase in inductor ripple current and higher output voltage ripple, not to mention reduced efficiency and compromised reliability. Note that the saturation current of an inductor generally decreases as its core temperature increases. Of course, accurate overcurrent protection is key to avoiding inductor saturation.

#### *9.1.1.2 Output Capacitors*

Ordinarily, the output capacitor energy storage of the regulator combined with the control loop response are prescribed to maintain the integrity of the output voltage within the dynamic (transient) tolerance specifications. The usual boundaries restricting the output capacitor in power management applications are driven by finite available PCB area, component footprint and profile, and cost. The capacitor parasitics – equivalent series resistance (ESR) and equivalent series inductance (ESL) – take greater precedence in shaping the load transient response of the regulator as the load step amplitude and slew rate increase.

The output capacitor, $C_{OUT}$, filters the inductor ripple current and provides a reservoir of charge for step-load transient events. Typically, ceramic capacitors provide extremely low ESR to reduce the output voltage ripple and noise spikes, while tantalum and electrolytic capacitors provide a large bulk capacitance in a relatively compact footprint for transient loading events.

Based on the static specification of peak-to-peak output voltage ripple denoted by $\Delta V_{OUT}$, choose an output capacitance that is larger than that given by 方程式 15.

Copyright © 2023 Texas Instruments Incorporated

$$C_{OUT} \geq \frac{\Delta I_L}{8 \cdot F_{SW} \sqrt{\Delta V_{OUT}^2 - \left(R_{ESR} \cdot \Delta I_L\right)^2}} \quad (15)$$

图 9-1 conceptually illustrates the relevant current waveforms during both load step-up and step-down transitions. As shown, the large-signal slew rate of the inductor current is limited as the inductor current ramps to match the new load-current level following a load transient. This slew-rate limiting exacerbates the deficit of charge in the output capacitor, which must be replenished as fast as possible during and after the load step-up transient. Similarly, during and after a load step-down transient, the slew rate limiting of the inductor current adds to the surplus of charge in the output capacitor that must be depleted as quickly as possible.

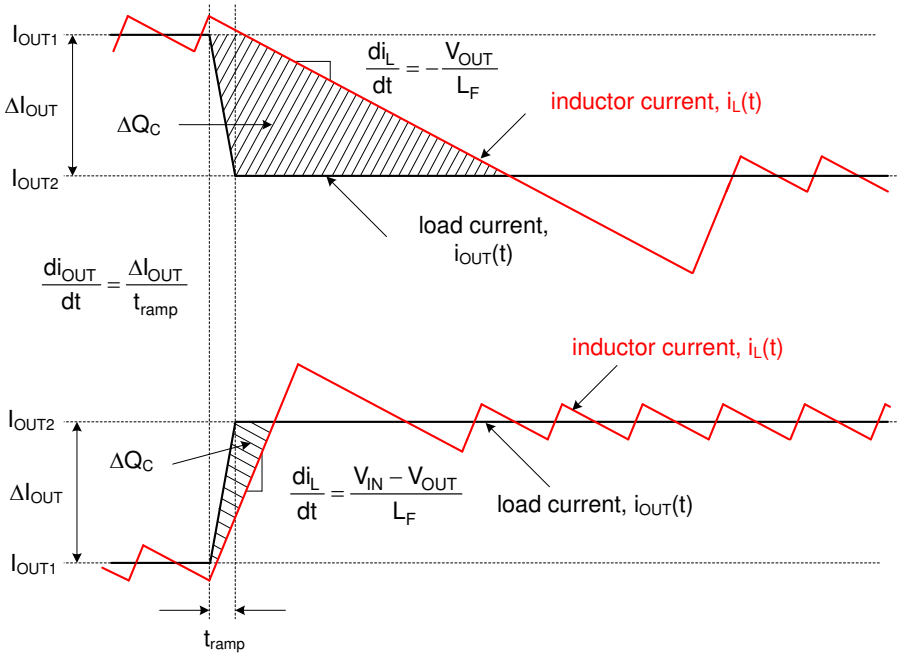

**图 9-1. Load Transient Response Representation Showing $C_{OUT}$ Charge Surplus or Deficit**

In a typical regulator application of 12-V input to low output voltage (for example, 3.3 V), the load-off transient represents the worst case in terms of output voltage transient deviation. In that conversion ratio application, the steady-state duty cycle is approximately 28% and the large-signal inductor current slew rate when the duty cycle collapses to zero is approximately $-V_{OUT}$ / L. Compared to a load-on transient, the inductor current takes much longer to transition to the required level. The surplus of charge in the output capacitor causes the output voltage to significantly overshoot. In fact, to deplete this excess charge from the output capacitor as quickly as possible, the inductor current must ramp below its nominal level following the load step. In this scenario, a large output capacitance can be advantageously employed to absorb the excess charge and minimize the voltage overshoot.

To meet the dynamic specification of output voltage overshoot during such a load-off transient (denoted as $\Delta V_{OVERSHOOT}$ with step reduction in output current given by $\Delta I_{OUT}$), the output capacitance must be larger than:

$$C_{OUT} \geq \frac{L_O \cdot \Delta I_{OUT}^2}{\left(V_{OUT} + \Delta V_{OVERSHOOT}\right)^2 - V_{OUT}^2} \quad (16)$$

The ESR of a capacitor is provided in the manufacturer's data sheet either explicitly as a specification or implicitly in the impedance versus frequency curve. Depending on type, size, and construction, electrolytic capacitors have significant ESR, 5 mΩ and above, and relatively large ESL, 5 nH to 20 nH. PCB traces contribute some parasitic resistance and inductance as well. Ceramic output capacitors, on the other hand, have low-ESR and ESL contributions at the switching frequency, and the capacitive impedance component

Copyright © 2023 Texas Instruments Incorporated

dominates. However, depending on package and voltage rating of the ceramic capacitor, the effective capacitance can drop quite significantly with applied DC voltage and operating temperature.

Ignoring the ESR term in 方程式 15 gives a quick estimation of the minimum ceramic capacitance necessary to meet the output ripple specification. Two to four 47-µF, 10-V, X7R capacitors in 1206 or 1210 footprint is a common choice for a 5-V output. Use 方程式 16 to determine if additional capacitance is necessary to meet the load-off transient overshoot specification.

A composite implementation of ceramic and electrolytic capacitors highlights the rationale for paralleling capacitors of dissimilar chemistries yet complementary performance. The frequency response of each capacitor is accretive in that each capacitor provides desirable performance over a certain portion of the frequency range. While the ceramic provides excellent mid- and high-frequency decoupling characteristics with its low ESR and ESL to minimize the switching frequency output ripple, the electrolytic device with its large bulk capacitance provides low-frequency energy storage to cope with load transient demands.

#### *9.1.1.3 Input Capacitors*

Input capacitors are necessary to limit the input ripple voltage to the buck power stage due to switching-frequency AC currents. TI recommends using X7S or X7R dielectric ceramic capacitors to provide low impedance and high RMS current rating over a wide temperature range. To minimize the parasitic inductance in the switching loop, position the input capacitors as close as possible to the drain of the high-side MOSFET and the source of the low-side MOSFET. The input capacitor RMS current for a single-channel buck regulator is given by 方程式 17.

$$I_{CIN,rms} = \sqrt{D \cdot \left( {I_{OUT}}^2 \cdot (1-D) + \frac{\Delta I_L^2}{12} \right)} \tag{17}$$

The highest input capacitor RMS current occurs at D = 0.5, at which point, the RMS current rating of the input capacitors must be greater than half the output current.

Ideally, the DC component of input current is provided by the input voltage source and the AC component by the input filter capacitors. Neglecting inductor ripple current, the input capacitors source current of amplitude ($I_{OUT}$ − $I_{IN}$) during the D interval and sinks $I_{IN}$ during the 1−D interval. Thus, the input capacitors conduct a square-wave current of peak-to-peak amplitude equal to the output current. It follows that the resultant capacitive component of AC ripple voltage is a triangular waveform. Together with the ESR-related ripple component, the peak-to-peak ripple voltage amplitude is given by 方程式 18.

$$\Delta V_{IN} = \frac{I_{OUT} \cdot D \cdot (1-D)}{F_{SW} \cdot C_{IN}} + I_{OUT} \cdot R_{ESR} \tag{18}$$

The input capacitance required for a particular load current, based on an input voltage ripple specification of $\Delta V_{IN}$, is given by 方程式 19.

$$C_{IN} \geq \frac{D \cdot (1-D) \cdot I_{OUT}}{F_{SW} \cdot (\Delta V_{IN} - R_{ESR} \cdot I_{OUT})} \tag{19}$$

Low-ESR ceramic capacitors can be placed in parallel with higher valued bulk capacitance to provide optimized input filtering for the regulator and damping to mitigate the effects of input parasitic inductance resonating with high-Q ceramics. One bulk capacitor of sufficiently high current rating and four 10-µF 50-V X7R ceramic decoupling capacitors are usually sufficient for 12-V battery automotive applications. Select the input bulk capacitor based on its ripple current rating and operating temperature range.

Of course, a two-channel buck regulator with 180° out-of-phase interleaved switching provides input ripple current cancellation and reduced input capacitor current stress. The above equations represent valid calculations when one output is disabled and the other output is fully loaded.

### 9.1.1.4 Power MOSFETs

The choice of power MOSFETs has significant impact on DC/DC regulator performance. A MOSFET with low on-state resistance, $R_{DS(on)}$, reduces conduction loss, whereas low parasitic capacitances enable faster transition times and reduced switching loss. Normally, the lower the $R_{DS(on)}$ of a MOSFET, the higher the gate charge and output charge ($Q_G$ and $Q_{OSS}$, respectively), and vice versa. As a result, the product of $R_{DS(on)}$ and $Q_G$ is commonly specified as a MOSFET figure-of-merit. Low thermal resistance of a given package ensures that the MOSFET power dissipation does not result in excessive MOSFET die temperature.

The main parameters affecting power MOSFET selection in a LM5148 application are as follows:

- $R_{DS(on)}$ at $V_{GS}$ = 5 V
- Drain-source voltage rating, $BV_{DSS}$, typically 40 V or 60 V, depending on the maximum input voltage
- Gate charge parameters at $V_{GS}$ = 5 V
- Output charge, $Q_{OSS}$, at the relevant input voltage
- Body diode reverse recovery charge, $Q_{RR}$
- Gate threshold voltage, $V_{GS(th)}$, derived from the Miller plateau evident in the $Q_G$ versus $V_{GS}$ plot in the MOSFET data sheet. With a Miller plateau voltage typically in the range of 2 V to 3 V, the 5-V gate drive amplitude of the LM5148 provides an adequately enhanced MOSFET when on and a margin against Cdv/dt shoot-through when off.

The MOSFET-related power losses for one channel are summarized by the equations presented in 表 9-1, where suffixes one and two represent high-side and low-side MOSFET parameters, respectively. While the influence of inductor ripple current is considered, second-order loss modes, such as those related to parasitic inductances and SW node ringing, are not included. Consult the LM5148 *Quickstart Calculator* to assist with power loss calculations.

**表 9-1. MOSFET Power Losses**

| POWER LOSS MODE | HIGH-SIDE MOSFET | LOW-SIDE MOSFET |
|---|---|---|
| MOSFET conduction(2) (3) | $P_{cond1} = D \cdot \left( {I_{OUT}}^2 + \frac{\Delta I_L^2}{12} \right) \cdot R_{DS(on)1}$ | $P_{cond2} = D' \cdot \left( {I_{OUT}}^2 + \frac{\Delta I_L^2}{12} \right) \cdot R_{DS(on)2}$ |
| MOSFET switching | $P_{sw1} = \frac{V_{IN} \cdot F_{SW}}{2} \left[ \left( I_{OUT} - \frac{\Delta I_L}{2} \right) \cdot t_R + \left( I_{OUT} + \frac{\Delta I_L}{2} \right) \cdot t_F \right]$ | Negligible |
| MOSFET gate drive(1) | $P_{Gate1} = V_{CC} \cdot F_{SW} \cdot Q_{G1}$ | $P_{Gate2} = V_{CC} \cdot F_{SW} \cdot Q_{G2}$ |
| MOSFET output charge(4) | $P_{Coss} = F_{SW} \cdot (V_{IN} \cdot Q_{oss2} + E_{oss1} - E_{oss2})$ | |
| Body diode conduction | N/A | $P_{cond_{BD}} = V_F \cdot F_{SW} \left[ \left( I_{OUT} + \frac{\Delta I_L}{2} \right) \cdot t_{dt1} + \left( I_{OUT} - \frac{\Delta I_L}{2} \right) \cdot t_{dt2} \right]$ |
| Body diode reverse recovery(5) | $P_{RR} = V_{IN} \cdot F_{SW} \cdot Q_{RR2}$ | |

(1) Gate drive loss is apportioned based on the internal gate resistance of the MOSFET, externally added series gate resistance and the relevant driver resistance of the LM5148.
(2) MOSFET $R_{DS(on)}$ has a positive temperature coefficient of approximately 4500 ppm/°C. The MOSFET junction temperature, $T_J$, and its rise over ambient temperature is dependent upon the device total power dissipation and its thermal impedance. When operating at or near minimum input voltage, make sure that the MOSFET $R_{DS(on)}$ is rated for the available gate drive voltage.
(3) D' = 1–D is the duty cycle complement.
(4) MOSFET output capacitances, $C_{oss1}$ and $C_{oss2}$, are highly non-linear with voltage. These capacitances are charged losslessly by the inductor current at high-side MOSFET turn-off. During turn-on, however, a current flows from the input to charge the output capacitance of the low-side MOSFET. $E_{oss1}$, the energy of $C_{oss1}$, is dissipated at turn-on, but this is offset by the stored energy $E_{oss2}$ on $C_{oss2}$.
(5) MOSFET body diode reverse recovery charge, $Q_{RR}$, depends on many parameters, particularly forward current, current transition speed, and temperature.

The high-side (control) MOSFET carries the inductor current during the PWM on-time (or D interval) and typically incurs most of the switching losses. It is, therefore, imperative to choose a high-side MOSFET that balances conduction and switching loss contributions. The total power dissipation in the high-side MOSFET is the sum of

Copyright © 2023 Texas Instruments Incorporated

the losses due to conduction, switching (voltage-current overlap), output charge, and typically two-thirds of the net loss attributed to body diode reverse recovery.

The low-side (synchronous) MOSFET carries the inductor current when the high-side MOSFET is off (or 1–D interval). The low-side MOSFET switching loss is negligible as it is switched at zero voltage – current just commutates from the channel to the body diode or vice versa during the transition dead-times. LM5148, with its adaptive gate drive timing, minimizes body diode conduction losses when both MOSFETs are off. Such losses scale directly with switching frequency.

In high step-down ratio applications, the low-side MOSFET carries the current for a large portion of the switching period. Therefore, to attain high efficiency, it is critical to optimize the low-side MOSFET for low $R_{DS(on)}$. In cases where the conduction loss is too high or the target $R_{DS(on)}$ is lower than available in a single MOSFET, connect two low-side MOSFETs in parallel. The total power dissipation of the low-side MOSFET is the sum of the losses due to channel conduction, body diode conduction, and typically one-third of the net loss attributed to body diode reverse recovery. The LM5148 is well suited to drive TI's portfolio of NexFET™ power MOSFETs.

#### *9.1.1.5 EMI Filter*

Switching regulators exhibit negative input impedance, which is lowest at the minimum input voltage. An underdamped LC filter exhibits a high output impedance at the resonant frequency of the filter. For stability, the filter output impedance must be less than the absolute value of the converter input impedance.

$$Z_{IN} = \left| -\frac{V_{IN(min)}^{2}}{P_{IN}} \right| \tag{20}$$

The passive EMI filter design steps are as follows:

- Calculate the required attenuation of the EMI filter at the switching frequency, where $C_{IN}$ represents the existing capacitance at the input of the switching converter.
- Input filter inductor $L_{IN}$ is usually selected between 1 µH and 10 µH, but it can be lower to reduce losses in a high-current design.
- Calculate input filter capacitor $C_F$.

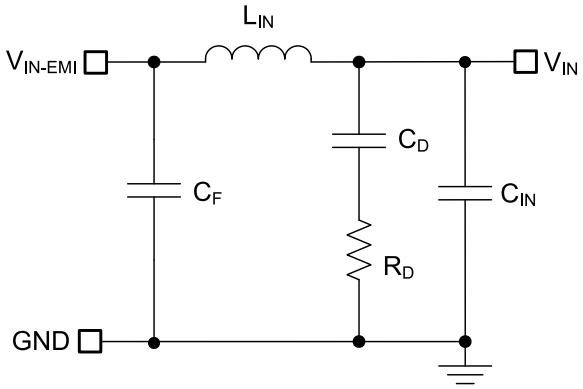

**图 9-2. Passive π-Stage EMI Filter for Buck Regulator**

By calculating the first harmonic current from the Fourier series of the input current waveform and multiplying it by the input impedance (the impedance is defined by the existing input capacitor $C_{IN}$), a formula is derived to obtain the required attenuation as shown by 方程式 21.

$$Attn = 20\log\left( \frac{I_{L(PEAK)}}{\pi^{2} \cdot F_{SW} \cdot C_{IN}} \cdot \sin\left(\pi \cdot D_{MAX}\right) \cdot \frac{1}{1\,\mu V} \right) - V_{MAX} \tag{21}$$

where

Copyright © 2023 Texas Instruments Incorporated

- $V_{MAX}$ is the allowed dBµV noise level for the applicable conducted EMI specification, for example CISPR 32 Class B.
- $C_{IN}$ is the existing input capacitance of the buck regulator.
- $D_{MAX}$ is the maximum duty cycle.
- $I_{PEAK}$ is the peak inductor current.

For filter design purposes, the current at the input can be modeled as a square-wave. Determine the passive EMI filter capacitance $C_F$ from 方程式 22.

$$C_F = \frac{1}{L_{IN}} \left( \frac{10^{\frac{|Attn|}{40}}}{2\pi \cdot F_{SW}} \right)^2 \tag{22}$$

Adding an input filter to a switching regulator modifies the control-to-output transfer function. The output impedance of the filter must be sufficiently small so that the input filter does not significantly affect the loop gain of the buck converter. The impedance peaks at the filter resonant frequency. The resonant frequency of the passive filter is given by 方程式 23.

$$f_{res} = \frac{1}{2\pi \cdot \sqrt{L_{IN} \cdot C_F}} \tag{23}$$

The purpose of $R_D$ is to reduce the peak output impedance of the filter at the resonant frequency. Capacitor $C_D$ blocks the DC component of the input voltage to avoid excessive power dissipation in $R_D$. Capacitor $C_D$ must have lower impedance than $R_D$ at the resonant frequency with a capacitance value greater than that of the input capacitor $C_{IN}$. This prevents $C_{IN}$ from interfering with the cutoff frequency of the main filter. Added input damping is needed when the output impedance of the filter is high at the resonant frequency (Q of filter formed by $L_{IN}$ and $C_{IN}$ is too high). An electrolytic capacitor $C_D$ can be used for input damping with a value given by 方程式 24.

$$C_D \geq 4 \cdot C_{IN} \tag{24}$$

Select the input damping resistor $R_D$ using 方程式 25.

$$R_D = \sqrt{\frac{L_{IN}}{C_{IN}}} \tag{25}$$

### 9.1.2 Error Amplifier and Compensation

图 9-3 shows a type-II compensator using a transconductance error amplifier (EA). The dominant pole of the EA open-loop gain is set by the EA output resistance, $R_{O\text{-}EA}$, and effective bandwidth-limiting capacitance, $C_{BW}$, as shown by 方程式 26.

$$G_{EA(open\,loop)}(s) = -\frac{g_m \cdot R_{O\text{-}EA}}{1 + s \cdot R_{O\text{-}EA} \cdot C_{BW}} \tag{26}$$

The EA high-frequency pole is neglected in the above expression. 方程式 27 calculates the compensator transfer function from output voltage to COMP node, including the gain contribution from the (internal or external) feedback resistor network.

Copyright © 2023 Texas Instruments Incorporated

$$G_c(s) = \frac{\hat{v}_c(s)}{\hat{v}_{out}(s)} = -\frac{V_{REF}}{V_{OUT}} \cdot \frac{g_m \cdot R_{O\text{-}EA} \cdot \left(1 + \frac{s}{\omega_{z1}}\right)}{\left(1 + \frac{s}{\omega_{p1}}\right) \cdot \left(1 + \frac{s}{\omega_{p2}}\right)} \quad (27)$$

where

- $V_{REF}$ is the feedback voltage reference of 0.8 V.
- $g_m$ is the EA gain transconductance of 1200 µS.
- $R_{O\text{-}EA}$ is the error amplifier output impedance of 64 MΩ.

$$\omega_{Z1} = \frac{1}{R_{COMP} \cdot C_{COMP}} \quad (28)$$

$$\omega_{p1} = \frac{1}{R_{O\text{-}EA} \cdot (C_{COMP} + C_{HF} + C_{BW})} \cong \frac{1}{R_{O\text{-}EA} \cdot C_{COMP}} \quad (29)$$

$$\omega_{p2} = \frac{1}{R_{COMP} \cdot \left(C_{COMP} \| (C_{HF} + C_{BW})\right)} \cong \frac{1}{R_{COMP} \cdot C_{HF}} \quad (30)$$

The EA compensation components create a pole close to the origin, a zero, and a high-frequency pole. Typically, $R_{COMP} << R_{O\text{-}EA}$ and $C_{COMP} >> C_{BW}$ and $C_{HF}$, so the approximations are valid.

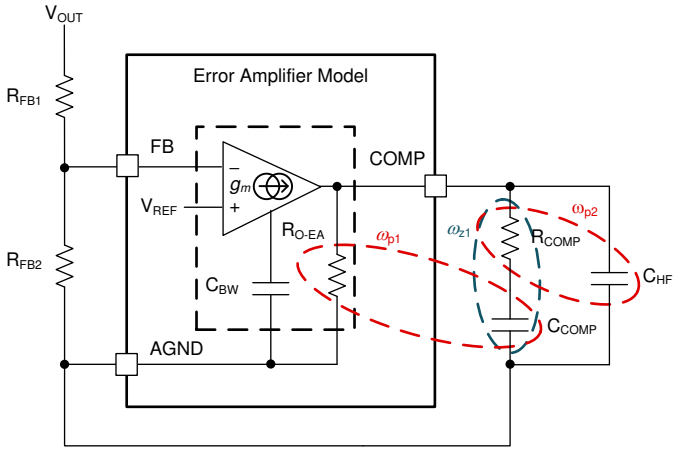

**图 9-3. Error Amplifier and Compensation Network**

## 9.2 Typical Applications

### 9.2.1 Design 1 – High Efficiency 2.1-MHz Synchronous Buck Regulator

图 9-4 shows the schematic diagram of a single-output synchronous buck regulator with an output voltage of 5 V and a rated load current of 8 A. In this example, the target half-load and full-load efficiencies are 93.5% and 92.5%, respectively, based on a nominal input voltage of 12 V that ranges from 5.5 V to 36 V. The switching frequency is set at 2.1 MHz by resistor $R_{RT}$. The 5-V output is connected to VCCX to reduce IC bias power dissipation and improve efficiency. An output voltage of 3.3 V is also feasible simply by connecting FB to VDDA.

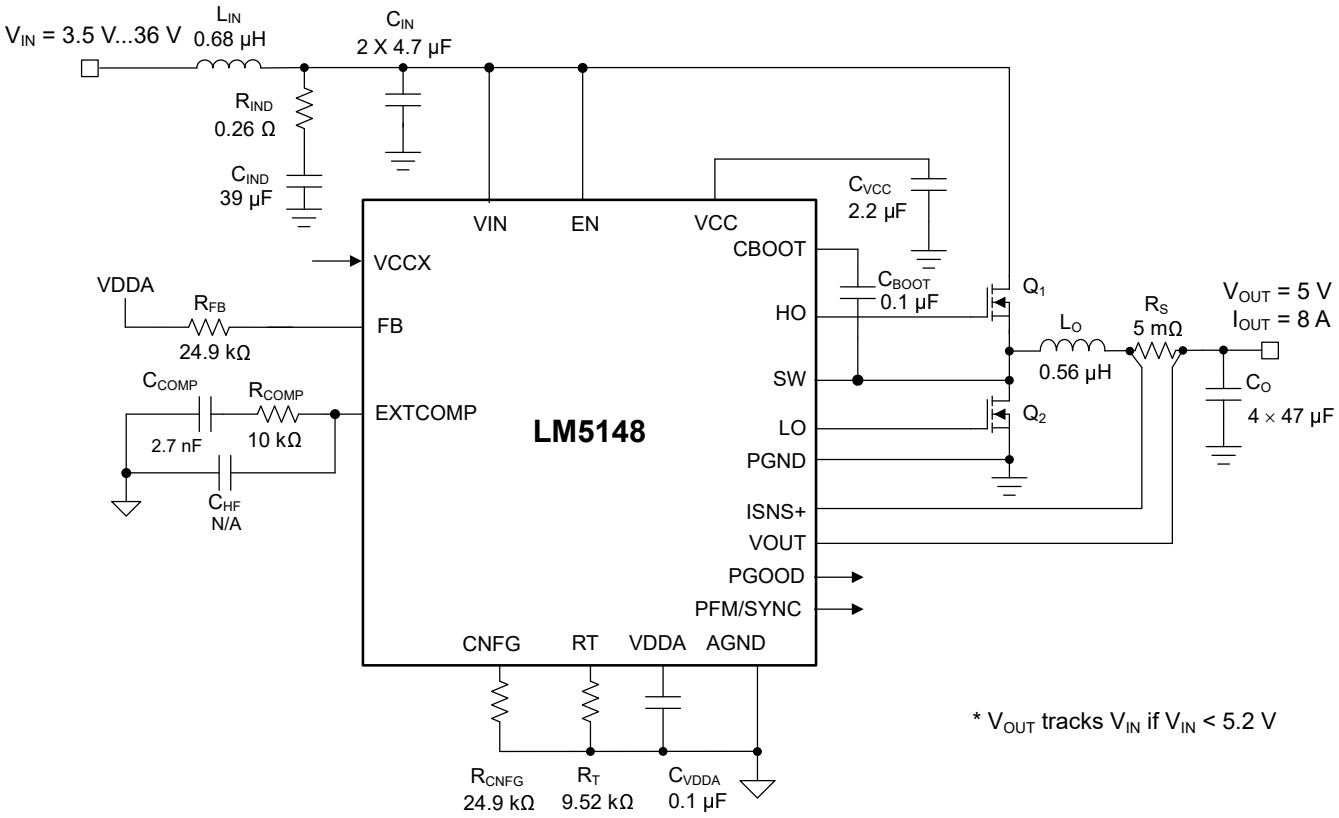

**图 9-4. Application Circuit 1 With LM5148 Buck Regulator Switching at 2.1 MHz**

**备注**

This and subsequent design examples are provided herein to showcase the LM5148 controller in several different applications. Depending on the source impedance of the input supply bus, an electrolytic capacitor may be required at the input to ensure stability, particularly at low input voltage and high output current operating conditions. See 节 9.3 for more details.

#### 9.2.1.1 Design Requirements

表 9-2 shows the intended input, output, and performance parameters for this design example. Refer to the LM25149-Q1EVM-2100 evaluation module.

**表 9-2. Design Parameters**

| DESIGN PARAMETER | VALUE |
|---|---|
| Input voltage range (steady state) | 8 V to 18 V |
| Min transient input voltage | 5.5 V |
| Max transient input voltage | 36 V |
| Output voltage | 5 V |
| Output current | 8 A |
| Switching frequency | 2.1 MHz |
| Output voltage regulation | ±1% |
| Standby current, no-load | 9.9 µA |
| Shutdown current | 2.3 µA |
| Soft-start time | 3 ms |

The switching frequency is set at 2.1 MHz by resistor $R_{RT}$. In terms of control loop performance, the target loop crossover frequency is 60 kHz with a phase margin greater than 50°.

The selected buck regulator powertrain components are cited in 表 9-3, and many of the components are available from multiple vendors. The MOSFETs in particular are chosen for lowest total conduction and switching power loss.. This design uses a low-DCR composite inductor, and ceramic output capacitors.

### 9.2.1.2 Detailed Design Procedure

#### 9.2.1.2.1 Custom Design with WEBENCH® Tools

Click here to create a custom design using the LM5148 device with the WEBENCH Power Designer.

1. Start by entering the input voltage ($V_{IN}$), output voltage ($V_{OUT}$), and output current ($I_{OUT}$) requirements.
2. Optimize the design for key parameters such as efficiency, footprint, and cost using the optimizer dial.
3. Compare the generated design with other possible solutions from Texas Instruments.

The WEBENCH Power Designer provides a customized schematic along with a list of materials with real-time pricing and component availability.

In most cases, these actions are available:

- Run electrical simulations to see important waveforms and circuit performance
- Run thermal simulations to understand board thermal performance
- Export customized schematic and layout into popular CAD formats
- Print PDF reports for the design, and share the design with colleagues

Get more information about WEBENCH tools at www.ti.com/WEBENCH.

#### 9.2.1.2.2 Custom Design with Excel Quickstart Tool

Select components based on the regulator specifications using the LM5148 *Quickstart Calculator* available for download from the LM5148 product folder.

#### 9.2.1.2.3 Buck Inductor

1. Use 方程式 31 to calculate the required buck inductance based on a 30% $\Delta I_{LO}$ inductor ripple current at nominal input voltages.

$$L_O = \frac{V_{OUT}}{\Delta I_{LO} \cdot F_{SW}} \cdot \left(1 - \frac{V_{OUT}}{V_{IN(nom)}}\right) = \frac{5\,V}{2.4\,A \cdot 2.1\,MHz} \cdot \left(1 - \frac{5\,V}{12\,V}\right) = 0.58\,\mu H \tag{31}$$

2. Select a standard inductor value of 0.56 µH or use a 0.68 µH to account for effective inductance derating over the current range of molded inductors. Use 方程式 32 to calculate the peak inductor currents at maximum steady-state input voltage. Subharmonic oscillation occurs with a duty cycle greater than 50% for peak current-mode control. For design simplification, the LM5148 has an internal slope compensation ramp proportional to the switching frequency that is added to the current sense signal to damp any tendency toward subharmonic oscillation.

$$I_{LO(PK)} = I_{OUT} + \frac{\Delta I_{LO}}{2} = I_{OUT} + \frac{V_{OUT}}{2 \cdot L_O \cdot F_{SW}} \cdot \left(1 - \frac{V_{OUT}}{V_{IN(max)}}\right) = 8\,A + \frac{5\,V}{0.56\,\mu H \cdot 2.1\,MHz} \cdot \left(1 - \frac{5\,V}{18\,V}\right) = 9.53\,A \tag{32}$$

3. Based on 方程式 9, use 方程式 33 to cross-check the inductance to set a slope compensation close to the ideal one times the inductor current downslope.

$$L_{O(sc)} = \frac{V_{OUT} \cdot R_S}{24 \cdot F_{SW}} = \frac{5\,V \cdot 5\,m\Omega}{24 \cdot 2.1\,MHz} = 0.5\,\mu H \tag{33}$$

#### 9.2.1.2.4 Current-Sense Resistance

1. Calculate the current-sense resistance based on a maximum peak current capability of at least 25% higher than the peak inductor current at full load to provide sufficient margin during start-up and load-on transients. Calculate the current sense resistances using 方程式 34.

$$R_S = \frac{V_{CS\text{-}TH}}{1.25 \cdot I_{LO(PK)}} = \frac{60\,mV}{1.25 \cdot 9.53\,A} = 5.04\,m\Omega \tag{34}$$

Copyright © 2023 Texas Instruments Incorporated

where

- $V_{CS-TH}$ is the 60-mV current limit threshold.

2. Select a standard resistance value of 5 mΩ for the shunt. An 0508 footprint component with wide aspect ratio termination design provides 1-W power rating, low parasitic series inductance, and compact PCB layout. Carefully adhere to the layout guidelines in 节 9.4.1 to make sure that noise and DC errors do not corrupt the differential current-sense voltages measured at the ISNS+ and VOUT pins.
3. Place the shunt resistor close to the inductor.
4. Use Kelvin-sense connections, and route the sense lines differentially from the shunt to the LM5148.
5. The CS-to-output propagation delay (related to the current limit comparator, internal logic, and power MOSFET gate drivers) causes the peak current to increase above the calculated current limit threshold. For a total propagation delay $t_{DELAY-ISNS+}$ of 40 ns, use 方程式 35 to calculate the worst-case peak inductor current with the output shorted.

$$I_{LO-PK(SC)} = \frac{V_{CS-TH}}{R_S} + \frac{V_{IN(max)} \cdot t_{DELAY-ISNS+}}{L_O} = \frac{60\,mV}{5\,m\Omega} + \frac{18\,V \cdot 45\,ns}{0.56\,\mu H} = 13.5\,A \tag{35}$$

6. Based on this result, select an inductor with saturation current greater than the result of 方程式 35 across the full operating temperature range.

#### 9.2.1.2.5 Output Capacitors

1. Use 方程式 36 to estimate the output capacitance required to manage the output voltage overshoot during a load-off transient (from full load to no load) assuming a load transient deviation specification of 1.5% (75 mV for a 5-V output).

$$C_{OUT} \geq \frac{L_O \cdot \Delta I_{OUT}{}^2}{\left(V_{OUT} + \Delta V_{OVERSHOOT}\right)^2 - V_{OUT}{}^2} = \frac{0.56\,\mu H \cdot \left(8\,A\right)^2}{\left(5\,V + 75\,mV\right)^2 - \left(5\,V\right)^2} = 47.4\,\mu F \tag{36}$$

2. Noting the voltage coefficient of ceramic capacitors where the effective capacitance decreases significantly with applied voltage, select four 47-µF, 10-V, X7R, 1210 ceramic output capacitors. Generally, when sufficient capacitance is used to satisfy the load-off transient response requirement, the voltage undershoot during a no-load to full-load transient is also satisfactory.
3. Use 方程式 37 to estimate the peak-peak output voltage ripple at nominal input voltage.

$$\Delta V_{OUT} = \sqrt{\left(\frac{\Delta I_{LO}}{8 \cdot F_{SW} \cdot C_{OUT}}\right)^2 + \left(R_{ESR} \cdot \Delta I_{LO}\right)^2} = \sqrt{\left(\frac{2.54\,A}{8 \cdot 2.1\,MHz \cdot 44\,\mu F}\right)^2 + \left(1\,m\Omega \cdot 2.54\,A\right)^2} = 4.3\,mV \tag{37}$$

where

- $R_{ESR}$ is the effective equivalent series resistance (ESR) of the output capacitors.
- 44 µF is the total effective (derated) ceramic output capacitance at 5 V.

4. Use 方程式 38 to calculate the output capacitor RMS ripple current using and verify that the ripple current is within the capacitor ripple current rating.

$$I_{CO(RMS)} = \frac{\Delta I_{LO}}{\sqrt{12}} = \frac{2.54\,A}{\sqrt{12}} = 0.73\,A \tag{38}$$

#### 9.2.1.2.6 Input Capacitors

A power supply input typically has a relatively high source impedance at the switching frequency. Good-quality input capacitors are necessary to limit the input ripple voltage. As mentioned earlier, dual-channel interleaved operation significantly reduces the input ripple amplitude. In general, the ripple current splits between the input capacitors based on the relative impedance of the capacitors at the switching frequency.

Copyright © 2023 Texas Instruments Incorporated

1. Select the input capacitors with sufficient voltage and RMS ripple current ratings.
2. Use 方程式 39 to calculate the input capacitor RMS ripple current assuming a worst-case duty-cycle operating point of 50%.

$$I_{CIN(RMS)} = I_{OUT} \cdot \sqrt{D \cdot (1-D)} = 8A \cdot \sqrt{0.5 \cdot (1-0.5)} = 4\,A \tag{39}$$

3. Use 方程式 40 to find the required input capacitance.

$$C_{IN} \geq \frac{D \cdot (1-D) \cdot I_{OUT}}{F_{SW} \cdot (\Delta V_{IN} - R_{ESR} \cdot I_{OUT})} = \frac{0.5 \cdot (1-0.5) \cdot 8\,A}{2.1MHz \cdot (120\,mV - 2m\Omega \cdot 8\,A)} = 9.2\ \mu F \tag{40}$$

where

- $\Delta V_{IN}$ is the input peak-to-peak ripple voltage specification.
- $R_{ESR}$ is the input capacitor ESR.

4. Recognizing the voltage coefficient of ceramic capacitors, select two 10-µF, 50-V, X7R, 1210 ceramic input capacitors. Place these capacitors adjacent to the power MOSFETs. See 节 9.4.1.1 for more details.
5. Use four 10-nF, 50-V, X7R, 0603 ceramic capacitors near the high-side MOSFET to supply the high di/dt current during MOSFET switching transitions. Such capacitors offer high self-resonant frequency (SRF) and low effective impedance above 100 MHz. The result is lower power loop parasitic inductance, thus minimizing switch-node voltage overshoot and ringing for lower conducted and radiated EMI signature. Refer to 节 9.4.1 for more details.

#### 9.2.1.2.7 Frequency Set Resistor

Calculate the RT resistance for a switching frequency of 2.1 MHz using 方程式 41. Choose a standard E96 value of 9.53 kΩ.

$$R_T(k\Omega) = \frac{\frac{10^6}{F_{SW}(kHz)} - 53}{45} = \frac{\frac{10^6}{2100kHz} - 53}{45} = 9.4k\Omega \tag{41}$$

#### 9.2.1.2.8 Feedback Resistors

If an output voltage setpoint other than 3.3 V or 5 V is required (or to measure a bode plot when using either of the fixed output voltage options), determine the feedback resistances using 方程式 42.

$$R_{FB1} = R_{FB2} \cdot \left( \frac{V_{OUT}}{V_{REF}} - 1 \right) = 15k\Omega \cdot \left( \frac{5\,V}{0.8\,V} - 1 \right) = 78.7k\Omega \tag{42}$$

#### 9.2.1.2.9 Compensation Components

Choose compensation components for a stable control loop using the procedure outlined as follows:

1. Based on a specified loop gain crossover frequency, $f_C$, of 60 kHz, use 方程式 43 to calculate $R_{COMP}$, assuming an effective output capacitance of 100 µF. Choose a standard value for $R_{COMP}$ of 10 kΩ.

$$R_{COMP} = 2\pi \cdot f_C \cdot \frac{V_{OUT}}{V_{REF}} \cdot \frac{R_S \cdot G_{CS}}{g_m} \cdot C_{OUT} = 2\pi \cdot 60kHz \cdot \frac{5\,V}{0.8\,V} \cdot \frac{5m\Omega \cdot 10}{1200\mu S} \cdot 100\mu F = 9.82k\Omega \tag{43}$$

2. To provide adequate phase boost at crossover while also allowing a fast settling time during a load or line transient, select $C_{COMP}$ to place a zero at the higher of (1) one tenth of the crossover frequency, or (2) the load pole. Choose a standard value for $C_{COMP}$ of 2.7 nF.

Copyright © 2023 Texas Instruments Incorporated

$$C_{COMP} = \frac{10}{2\pi \cdot f_C \cdot R_{COMP}} = \frac{10}{2\pi \cdot 60\,kHz \cdot 10\,k\Omega} = 2.65\ nF \quad (44)$$

Such a low capacitance value also helps to avoid output voltage overshoot when recovering from dropout (when the input voltage is less than the output voltage setpoint and $V_{COMP}$ is railed high).

3. Calculate $C_{HF}$ to create a pole at the ESR zero and to attenuate high-frequency noise at COMP. $C_{BW}$ is the bandwidth-limiting capacitance of the error amplifier. $C_{HF}$ can not be significant enough to be necessary in some designs, like this one. $C_{HF}$ can be unpopulated, or used with a small 22 pF for more noise filtering.

$$C_{HF} = \frac{1}{2\pi \cdot f_{ESR} \cdot R_{COMP}} - C_{BW} = \frac{1}{2\pi \cdot 500\,kHz \cdot 10\,k\Omega} - 31\,pF = 0.8\ pF \quad (45)$$

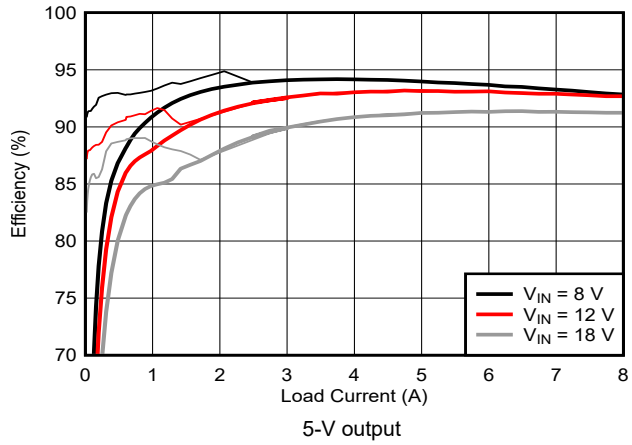

**备注**

Set a fast loop with high $R_{COMP}$ and low $C_{COMP}$ values to improve the response when recovering from operation in dropout.

### 9.2.2 Design 2 – High Efficiency 48-V to 12-V 400-kHz Synchronous Buck Regulator

图 9-17 shows the schematic diagram of a single-output synchronous buck regulator with an output voltage of 12 V and a rated load current of 8 A. In this example, the target half-load and full-load efficiencies are 95% and 94%, respectively, based on a nominal input voltage of 48 V that ranges from 12.5 V to 72 V. The switching frequency is set at 400 kHz by resistor $R_{RT}$

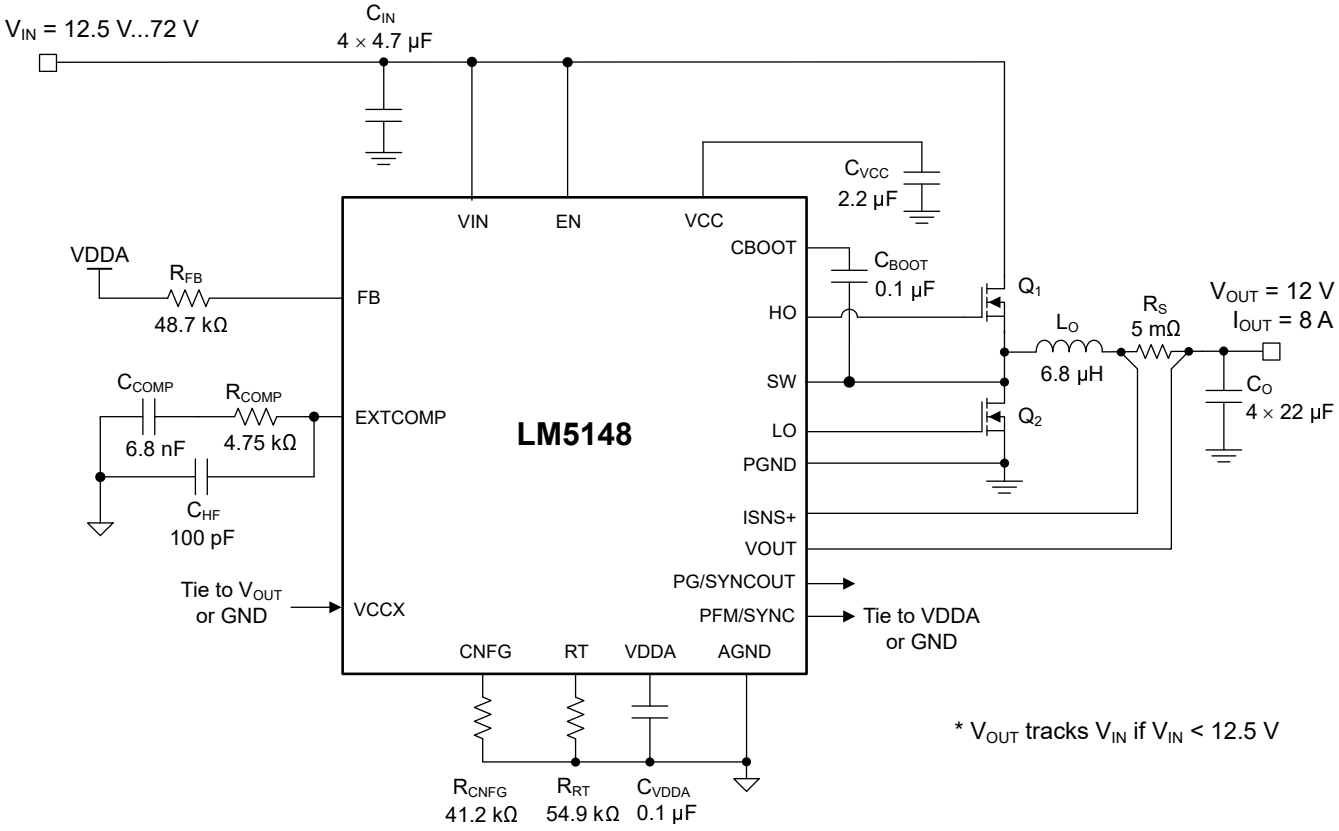

**图 9-17. Application Circuit 2 With LM5148 Buck Regulator Switching at 400 kHz**

#### *9.2.2.1 Design Requirements*

表 9-4 shows the intended input, output, and performance parameters for this design example. Reference the LM5149-Q1EVM-400 evaluation module.

**表 9-4. Design Parameters**

| DESIGN PARAMETER | VALUE |

### 9.2.3 Design 3 – High Efficiency 440-kHz Synchronous Buck Regulator

图 9-28 shows the schematic diagram of a single-output synchronous buck regulator with an output voltage of 5 V and a rated load current of 10 A. In this example, the target half-load and full-load efficiencies are 97% and 95%, respectively, based on a nominal input voltage of 12 V that ranges from 5.5 V to 36 V. The switching frequency is set at 440 kHz by resistor $R_{RT}$. The 5-V output is connected to VCCX to reduce IC bias power dissipation and improve efficiency. An output voltage of 3.3 V is also feasible simply by connecting FB to VDDA (tie VCCX to GND in this case).

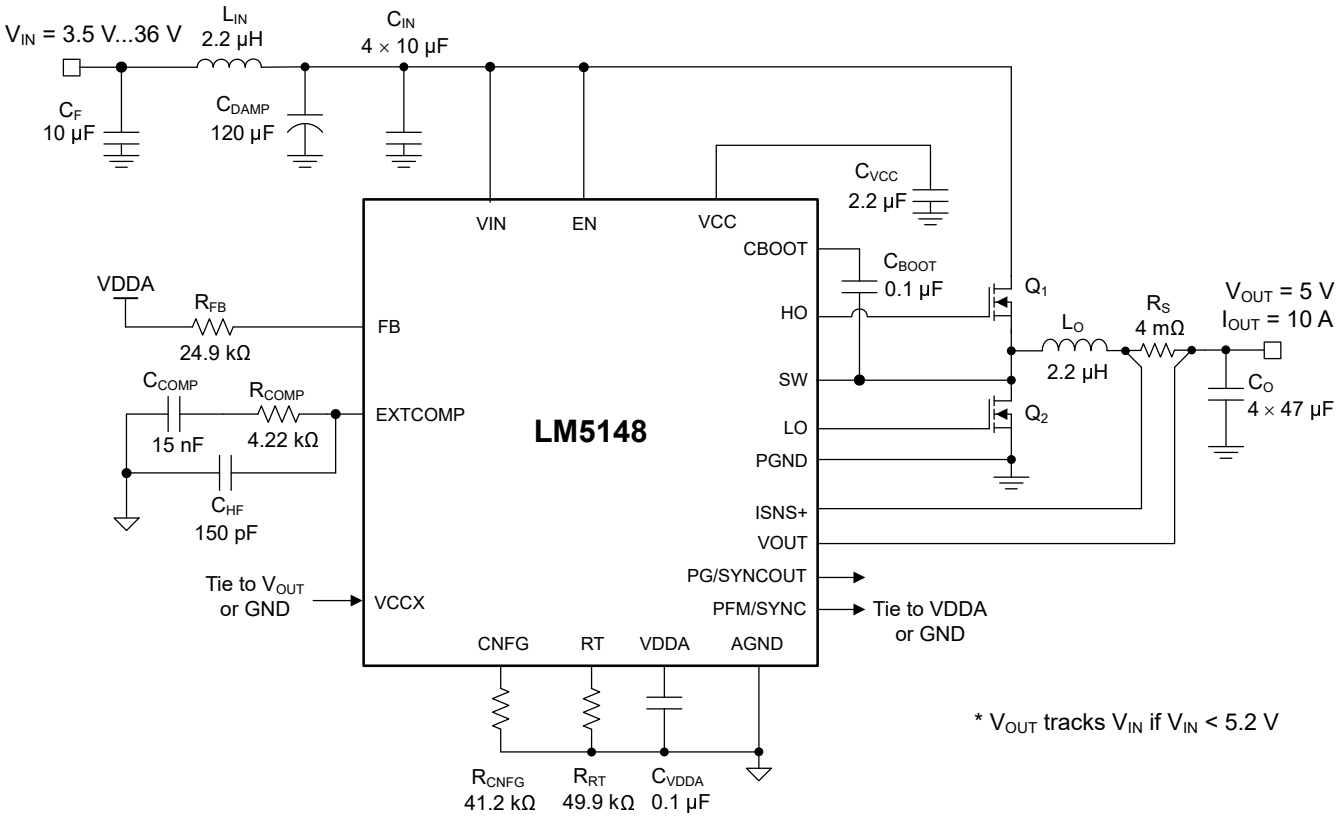

**图 9-28. Application Circuit 3 with LM5148 Buck Regulator Switching at 440 kHz**

### 9.2.4 Design 4 – Dual-Phase 400-kHz 20-A Synchronous Buck Regulator

图 9-39 shows the schematic diagram of a dual-phase synchronous buck regulator with output voltage of 3.3 V and a rated load current of 20 A. In this example, the target half-load and full-load efficiencies are 95% and 92%, respectively, based on a nominal input voltage of 12 V that ranges from 4 V to 36 V. The switching frequency is set at 400 kHz by resistors $R_{RT1}$ and $R_{RT2}$.

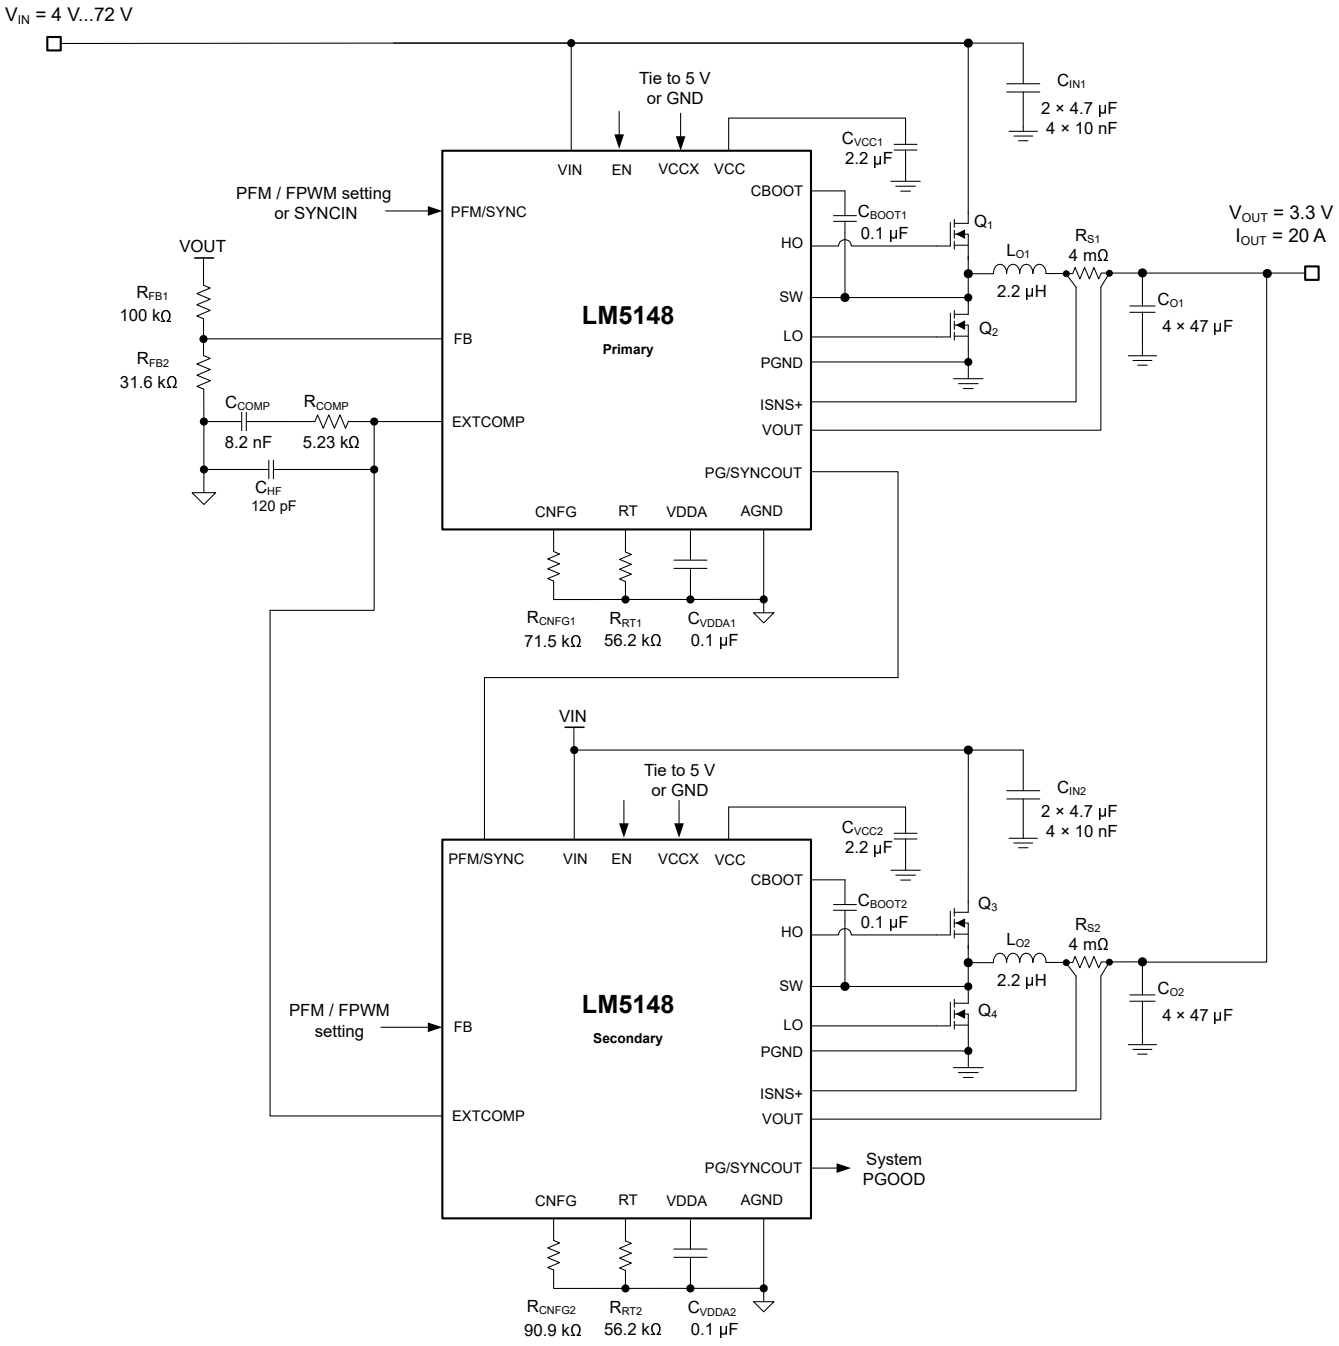

**图 9-39. Application Circuit 4 with Two LM5148 Buck Regulators Switching at 400 kHz**

Copyright © 2023 Texas Instruments Incorporated

**备注**

A design with 3 or more phases is feasible when appropriately added phase-shifted clock signals are available. For example, a 4-phase design requires 4 LM5148 controllers with 0°, 90°, 180° and 270° external SYNC signals to achieve the ideal phase separation of 360° divided by the total number of phases.

#### 9.2.4.1 Design Requirements

表 9-8 shows the intended input, output, and performance parameters for this design example.

**表 9-8. Design Parameters**

| DESIGN PARAMETER | VALUE |
|---|---|
| Input voltage range (steady-state) | 8 V to 72 V |
| Min transient input voltage | 4 V |
| Max transient input voltage | 80 V |
| Output voltage | 3.3 V |
| Output current | 20 A |
| Switching frequency | 400 kHz |
| Output voltage regulation | ±1% |
| Standby current, no-load | 44 µA |
| Shutdown current | 4.6 µA |
| Soft-start time | 3 ms |

The switching frequency is set at 400 kHz by resistors $R_{RT1}$ and $R_{RT2}$. The selected buck regulator powertrain components are cited in 表 9-9, and many of the components are available from multiple vendors. The MOSFETs in particular are chosen for both lowest conduction and switching power loss, as discussed in detail in 节 9.1.1.4.

## 9.3 Power Supply Recommendations

The LM5148 buck controller is designed to operate from a wide input voltage range of 3.5 V to 80 V. The characteristics of the input supply must be compatible with the *Absolute Maximum Ratings* and *Recommended Operating Conditions*. In addition, the input supply must be capable of delivering the required input current to the fully loaded regulator. Estimate the average input current with 方程式 46.

$$I_{IN} = \frac{P_{OUT}}{V_{IN} \cdot \eta} \tag{46}$$

where

- η is the efficiency

If the regulator is connected to an input supply through long wires or PCB traces with a large impedance, take special care to achieve stable performance. The parasitic inductance and resistance of the input cables can have an adverse affect on converter operation. The parasitic inductance in combination with the low-ESR ceramic input capacitors form an underdamped resonant circuit. This circuit can cause overvoltage transients at VIN each time the input supply is cycled ON and OFF. The parasitic resistance causes the input voltage to dip during a load transient. The best way to solve such issues is to reduce the distance from the input supply to the regulator and use an aluminum or tantalum input capacitor in parallel with the ceramics. The moderate ESR of the electrolytic capacitors helps damp the input resonant circuit and reduce any voltage overshoots. A capacitance in the range of 10 µF to 47 µF is usually sufficient to provide parallel input damping and helps to hold the input voltage steady during large load transients.

An EMI input filter is often used in front of the regulator that, unless carefully designed, can lead to instability as well as some of the effects mentioned above. The *Simple Success with Conducted EMI for DC-DC Converters* application report provides helpful suggestions when designing an input filter for any switching regulator.

## 9.4 Layout

### 9.4.1 Layout Guidelines

Proper PCB design and layout is important in a high-current, fast-switching circuit (with high current and voltage slew rates) to achieve a robust and reliable design. As expected, certain issues must be considered before designing a PCB layout using the LM5148. The high-frequency power loop of a buck regulator power stage is denoted by loop 1 in the shaded area of 图 9-46. The topological architecture of a buck regulator means that particularly high di/dt current flows in the components of loop 1, and it becomes mandatory to reduce the parasitic inductance of this loop by minimizing its effective loop area. Also important are the gate drive loops of the high-side and low-side MOSFETs, denoted by 2 and 3, respectively, in 图 9-46.

Copyright © 2023 Texas Instruments Incorporated

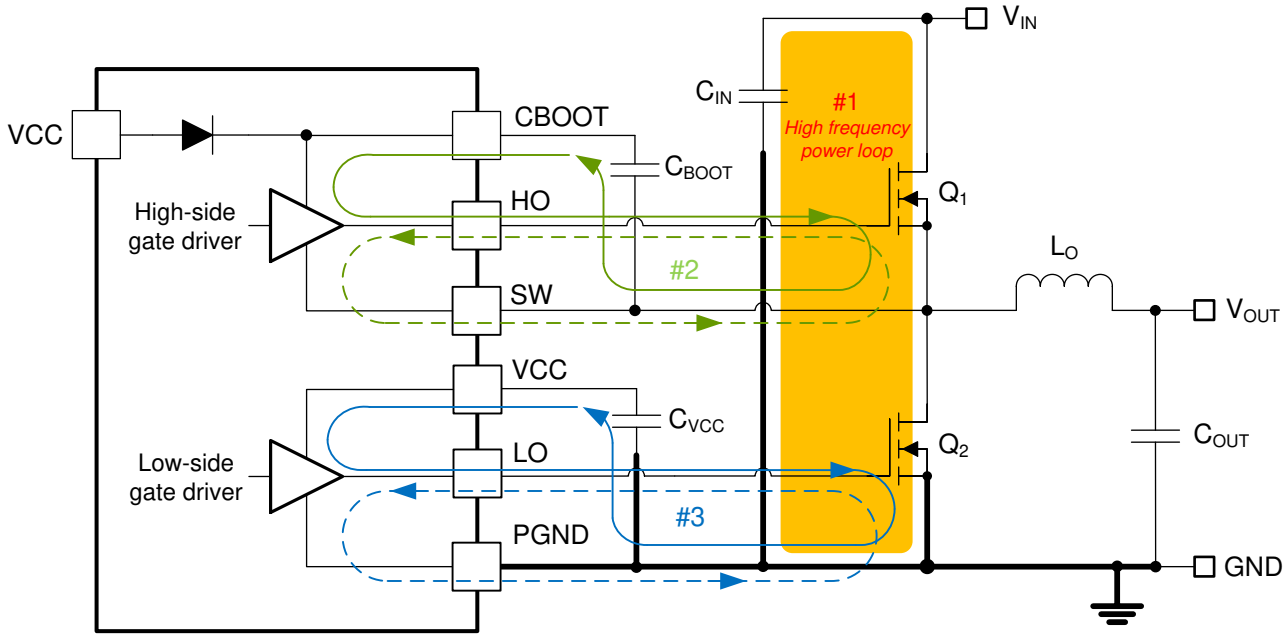

**图 9-46. DC/DC Regulator Ground System With Power Stage and Gate Drive Circuit Switching Loops**

### *9.4.1.1 Power Stage Layout*

- Input capacitors, output capacitors, and MOSFETs are the constituent components of the power stage of a buck regulator and are typically placed on the top side of the PCB (solder side). The benefits of convective heat transfer are maximized because of leveraging any system-level airflow. In a two-sided PCB layout, small-signal components are typically placed on the bottom side (component side). Insert at least one inner plane, connected to ground, to shield and isolate the small-signal traces from noisy power traces and lines.
- The DC/DC regulator has several high-current loops. Minimize the area of these loops to suppress generated switching noise and optimize switching performance.
  - Loop 1: The most important loop area to minimize is the path from the input capacitor or capacitors through the high- and low-side MOSFETs, and back to the capacitor or capacitors through the ground connection. Connect the input capacitor or capacitors negative terminal close to the source of the low-side MOSFET (at ground). Similarly, connect the input capacitor or capacitors positive terminal close to the drain of the high-side MOSFET (at VIN). Refer to loop 1 of 图 9-46.
  - Another loop, not as critical as loop 1, is the path from the low-side MOSFET through the inductor and output capacitor or capacitors, and back to source of the low-side MOSFET through ground. Connect the source of the low-side MOSFET and negative terminal of the output capacitor or capacitors at ground as close as possible.
- The PCB trace defined as SW node, which connects to the source of the high-side (control) MOSFET, the drain of the low-side (synchronous) MOSFET and the high-voltage side of the inductor, must be short and wide. However, the SW connection is a source of injected EMI and thus must not be too large.
- Follow any layout considerations of the MOSFETs as recommended by the MOSFET manufacturer, including pad geometry and solder paste stencil design.
- The SW pin connects to the switch node of the power conversion stage and acts as the return path for the high-side gate driver. The parasitic inductance inherent to loop 1 in 图 9-46 and the output capacitance ($C_{OSS}$) of both power MOSFETs form a resonant circuit that induces high frequency (greater than 50 MHz) ringing at the SW node. The voltage peak of this ringing, if not controlled, can be significantly higher than the input voltage. Make sure that the peak ringing amplitude does not exceed the absolute maximum rating limit for the SW pin. In many cases, a series resistor and capacitor snubber network connected from the SW node to GND damps the ringing and decreases the peak amplitude. Provide provisions for snubber network

Copyright © 2023 Texas Instruments Incorporated

components in the PCB layout. If testing reveals that the ringing amplitude at the SW pin is excessive, then include snubber components as needed.

#### 9.4.1.2 Gate-Drive Layout

The LM25148-Q1 high-side and low-side gate drivers incorporate short propagation delays, adaptive dead-time control, and low-impedance output stages capable of delivering large peak currents with very fast rise and fall times to facilitate rapid turn-on and turn-off transitions of the power MOSFETs. Very high di/dt can cause unacceptable ringing if the trace lengths and impedances are not well controlled.

Minimization of stray or parasitic gate loop inductance is key to optimizing gate drive switching performance, whether it be series gate inductance that resonates with MOSFET gate capacitance or common source inductance (common to gate and power loops) that provides a negative feedback component opposing the gate drive command, thereby increasing MOSFET switching times. The following loops are important:

- Loop 2: high-side MOSFET, $Q_1$. During the high-side MOSFET turnon, high current flows from the bootstrap (boot) capacitor through the gate driver and high-side MOSFET, and back to the negative terminal of the boot capacitor through the SW connection. Conversely, to turn off the high-side MOSFET, high current flows from the gate of the high-side MOSFET through the gate driver and SW, and back to the source of the high-side MOSFET through the SW trace. Refer to loop 2 of 图 9-46.
- Loop 3: low-side MOSFET, $Q_2$. During the low-side MOSFET turnon, high current flows from the VCC decoupling capacitor through the gate driver and low-side MOSFET, and back to the negative terminal of the capacitor through ground. Conversely, to turn off the low-side MOSFET, high current flows from the gate of the low-side MOSFET through the gate driver and GND, and back to the source of the low-side MOSFET through ground. Refer to loop 3 of 图 9-46.

TI strongly recommends following circuit layout guidelines when designing with high-speed MOSFET gate drive circuits.

- Connections from gate driver outputs, HO and LO, to the respective gates of the high-side or low-side MOSFETs must be as short as possible to reduce series parasitic inductance. Be aware that peak gate drive currents can be as high as 3.3 A. Use 0.65 mm (25 mils) or wider traces. Use via or vias, if necessary, of at least 0.5 mm (20 mils) diameter along these traces. Route HO and SW gate traces as a differential pair from the LM5148 to the high-side MOSFET, taking advantage of flux cancellation.
- Minimize the current loop path from the VCC and HB pins through their respective capacitors as these provide the high instantaneous current, up to 3.3 A, to charge the MOSFET gate capacitances. Specifically, locate the bootstrap capacitor, $C_{BST}$, close to the CBOOT and SW pins of the LM25148-Q1 to minimize the area of loop 2 associated with the high-side driver. Similarly, locate the VCC capacitor, $C_{VCC}$, close to the VCC and PGND pins of the LM5148 to minimize the area of loop 3 associated with the low-side driver.

#### 9.4.1.3 PWM Controller Layout

With the proviso to locate the controller as close as possible to the power MOSFETs to minimize gate driver trace runs, the components related to the analog and feedback signals as well as current sensing are considered in the following:

- Separate power and signal traces, and use a ground plane to provide noise shielding.
- Place all sensitive analog traces and components related to COMP, FB, ISNS+, and RT away from high-voltage switching nodes such as SW, HO, LO, or CBOOT to avoid mutual coupling. Use internal layer or layers as ground plane or planes. Pay particular attention to shielding the feedback (FB) and current sense (ISNS+ and VOUT) traces from power traces and components.
- Locate the upper and lower feedback resistors (if required) close to the FB pin, keeping the FB trace as short as possible. Route the trace from the upper feedback resistor to the required output voltage sense point at the load.
- Route the ISNS+ and VOUT sense traces as differential pairs to minimize noise pickup and use Kelvin connections to the applicable shunt resistor (if shunt current sensing is used) or to the sense capacitor (if inductor DCR current sensing is used).
- Minimize the loop area from the VCC and VIN pins through their respective decoupling capacitors to the PGND pin. Locate these capacitors as close as possible to the LM5148.

Copyright © 2023 Texas Instruments Incorporated

#### 9.4.1.4 Thermal Design and Layout

The useful operating temperature range of a PWM controller with integrated gate drivers and bias supply LDO regulator is greatly affected by the following:

- Average gate drive current requirements of the power MOSFETs
- Switching frequency
- Operating input voltage (affecting bias regulator LDO voltage drop and hence its power dissipation)
- Thermal characteristics of the package and operating environment

For a PWM controller to be useful over a particular temperature range, the package must allow for the efficient removal of the heat produced while keeping the junction temperature within rated limits. The LM25148-Q1 controller is available in a small 4-mm × 4-mm 24-pin VQFN PowerPAD™ integrated circuit package to cover a range of application requirements. 节 9.4.1.4 summarizes the thermal metrics of this package.

The 24-pin VQFN package offers a means of removing heat from the semiconductor die through the exposed thermal pad at the base of the package. While the exposed pad of the package is not directly connected to any leads of the package, it is thermally connected to the substrate of the LM25148-Q1 device (ground). This allows a significant improvement in heat sinking, and it becomes imperative that the PCB is designed with thermal lands, thermal vias, and a ground plane to complete the heat removal subsystem. The exposed pad of the LM25148-Q1 is soldered to the ground-connected copper land on the PCB directly underneath the device package, reducing the thermal resistance to a very low value.

Numerous vias with a 0.3-mm diameter connected from the thermal land to the internal and solder-side ground plane or planes are vital to help dissipation. In a multi-layer PCB design, a solid ground plane is typically placed on the PCB layer below the power components. Not only does this provide a plane for the power stage currents to flow but it also represents a thermally conductive path away from the heat generating devices.

The thermal characteristics of the MOSFETs also are significant. The drain pads of the high-side MOSFETs are normally connected to a VIN plane for heat sinking. The drain pads of the low-side MOSFETs are tied to the SW plane, but the SW plane area is purposely kept as small as possible to mitigate EMI concerns.

#### 9.4.1.5 Ground Plane Design

As mentioned previously, TI recommends using one or more of the inner PCB layers as a solid ground plane. A ground plane offers shielding for sensitive circuits and traces and also provides a quiet reference potential for the control circuitry. In particular, a full ground plane on the layer directly underneath the power stage components is essential. Connect the source terminal of the low-side MOSFET and return terminals of the input and output capacitors to this ground plane. Connect the PGND and AGND pins of the controller at the DAP and then connect to the system ground plane using an array of vias under the DAP. The PGND nets contain noise at the switching frequency and can bounce because of load current variations. The power traces for PGND, VIN, and SW can be restricted to one side of the ground plane, for example on the top layer. The other side of the ground plane contains much less noise and is ideal for sensitive analog trace routes.

### 9.4.2 Layout Example

图 9-47 shows a single-sided layout of a synchronous buck regulator with discrete power MOSFETs, Q1 and Q2, in SON 5-mm × 6-mm case size. The power stage is surrounded by a GND pad geometry to connect an EMI shield if needed. The design uses layer 2 of the PCB as a power-loop return path directly underneath the top layer to create a low-area switching power loop of approximately 2 mm². This loop area, and hence parasitic inductance, must be as small as possible to minimize EMI as well as switch-node voltage overshoot and ringing.

The high-frequency power loop current flows through MOSFETs Q1 and Q2, through the power ground plane on layer 2, and back to VIN through the 0603 ceramic capacitors C15 through C18. The currents flowing in opposing directions in the vertical loop configuration provide field self-cancellation, reducing parasitic inductance. 图 9-49 shows a side view to illustrate the concept of creating a low-profile, self-canceling loop in a multilayer PCB structure. The layer-2 GND plane layer, shown in 图 9-48, provides a tightly-coupled current return path directly under the MOSFETs to the source terminals of Q2.

Four 10-nF input capacitors with small 0402 or 0603 case size are placed in parallel very close to the drain of Q1. The low equivalent series inductance (ESL) and high self-resonant frequency (SRF) of the small footprint capacitors yield excellent high-frequency performance. The negative terminals of these capacitors are connected to the layer-2 GND plane with multiple 12-mil (0.3-mm) diameter vias, further minimizing parasitic loop inductance.

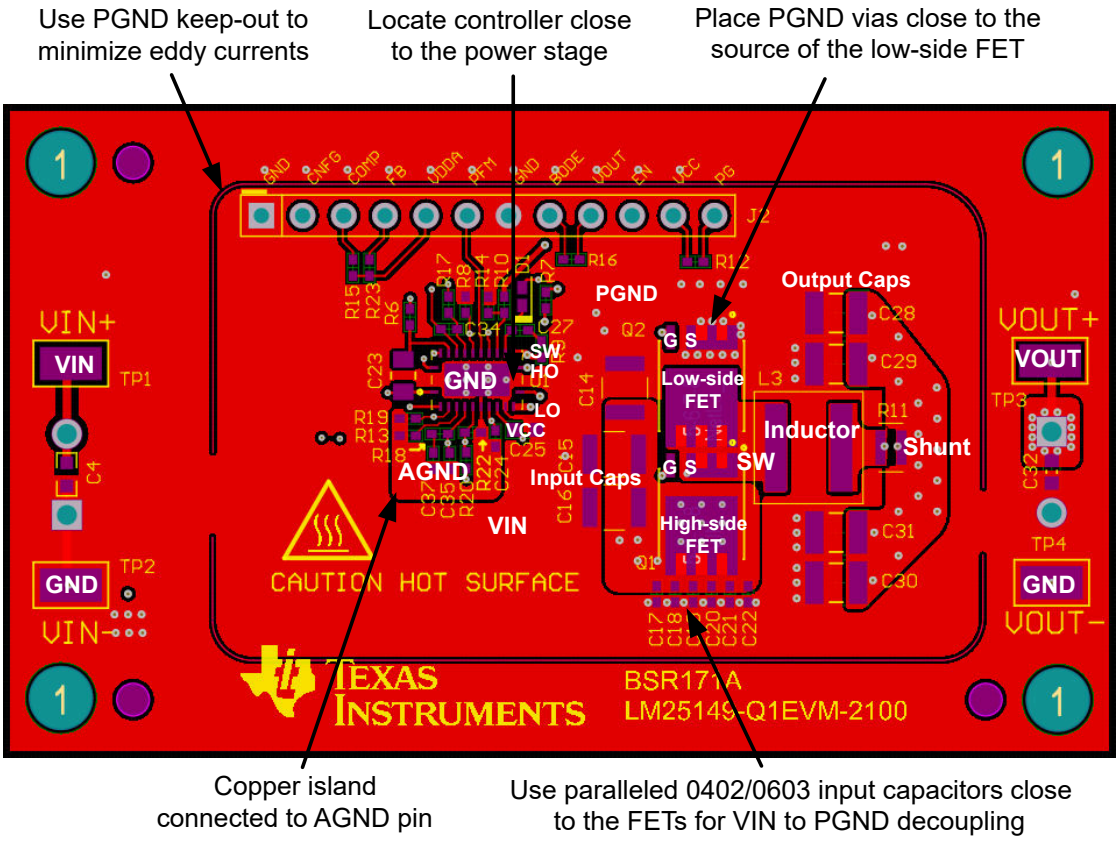

**图 9-47. PCB Top Layer – High Density, Single-sided Design**

Additional guidelines to improve noise immunity and reduce EMI are as follows:

- Make the ground connections to the LM5148 controller as shown in 图 9-47. Create a power ground directly connected to all high-power components and an analog ground plane for sensitive analog components. The analog ground plane for AGND and power ground plane for PGND must be connected at a single point directly under the IC – at the die attach pad (DAP).

Copyright © 2023 Texas Instruments Incorporated

- Connect the MOSFETs (switch node) directly to the inductor terminal with short copper connections (without vias) as this net has high dv/dt and contributes to radiated EMI. The single-layer routing of the switch-node connection means that switch-node vias with high dv/dt do not appear on the bottom side of the PCB. This avoids e-field coupling to the reference ground plane during the EMI test. VIN and PGND plane copper pours shield the polygon connecting the MOSFETs to the inductor terminal, further reducing the radiated EMI signature.
- Place the *EMI filter* components on the bottom side of the PCB so that they are shielded from the power stage components on the top side.

# 10 Device and Documentation Support

## 10.1 Device Support

### 10.1.1 Development Support

With an input operating voltage as low as 3.5 V and up to 100 V as specified in 表 10-1, the LM(2)514x family of synchronous buck controllers from TI provides flexibility, scalability and optimized solution size for a range of applications. These controllers enable DC/DC solutions with high density, low EMI and increased flexibility. Available EMI mitigation features include dual-random spread spectrum (DRSS) or triangular spread spectrum (TRSS), split gate driver outputs for slew rate (SR) control, and integrated active EMI filtering (AEF).

**表 10-1. Synchronous Buck DC/DC Controller Family**

| DC/DC CONTROLLER | SINGLE or DUAL | $V_{IN}$ RANGE | CONTROL METHOD | GATE DRIVE VOLTAGE | SYNC OUTPUT | EMI MITIGATION |
|---|---|---|---|---|---|---|
| LM25141 | Single | 3.8 V to 42 V | Peak current mode | 5 V | N/A | SR control, TRSS |
| LM25143 | Dual | 3.5 V to 42 V | Peak current mode | 5 V | 90° phase shift | SR control, TRSS |
| LM25145 | Single | 6 V to 42 V | Voltage mode | 7.5 V | 180° phase shift | N/A |
| LM25148 | Single | 3.5 V to 42 V | Peak current mode | 5 V | 180° phase shift | DRSS |
| LM25149 | Single | 3.5 V to 42 V | Peak current mode | 5 V | 180° phase shift | AEF, DRSS |
| LM5141 | Single | 3.8 V to 42 V | Peak current mode | 5 V | N/A | SR control, TRSS |
| LM5143 | Dual | 3.5 V to 65 V | Peak current mode | 5 V | 90° phase shift | SR control, TRSS |
| LM5145 | Single | 6 V to 75 V | Voltage mode | 7.5 V | 180° phase shift | N/A |
| LM5146 | Single | 5.5 V to 100 V | Voltage mode | 7.5 V | 180° phase shift | N/A |
| LM5148 | Single | 3.5 V to 80 V | Peak current mode | 5 V | 180° phase shift | DRSS |
| LM5149 | Single | 3.5 V to 80 V | Peak current mode | 5 V | 180° phase shift | AEF, DRSS |

#### *10.1.1.1 Custom Design with WEBENCH® Tools*

Click here to create a custom design using the LM5148 device with the WEBENCH Power Designer.

1. Start by entering the input voltage ($V_{IN}$), output voltage ($V_{OUT}$), and output current ($I_{OUT}$) requirements.

Copyright © 2023 Texas Instruments Incorporated

2. Optimize the design for key parameters such as efficiency, footprint, and cost using the optimizer dial.
3. Compare the generated design with other possible solutions from Texas Instruments.

The WEBENCH Power Designer gives a customized schematic along with a list of materials with real-time pricing and component availability.

In most cases, these actions are available:

- Run electrical simulations to see important waveforms and circuit performance
- Run thermal simulations to understand board thermal performance
- Export customized schematic and layout into popular CAD formats
- Print PDF reports for the design, and share the design with colleagues

## PACKAGING INFORMATION

| Orderable part number | Status (1) | Material type (2) | Package \| Pins | Package qty \| Carrier | RoHS (3) | Lead finish/ Ball material (4) | MSL rating/ Peak reflow (5) | Op temp (°C) | Part marking (6) |
|---|---|---|---|---|---|---|---|---|---|
| LM5148RGYR | Active | Production | VQFN (RGY) \| 24 | 3000 \| LARGE T&R | Yes | Call TI \| Sn | Level-2-260C-1 YEAR | -40 to 125 | LM5148 |
| LM5148RGYR.A | Active | Production | VQFN (RGY) \| 24 | 3000 \| LARGE T&R | Yes | SN | Level-2-260C-1 YEAR | -40 to 125 | LM5148 |

(1) **Status:** For more details on status, see our product life cycle.

(2) **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

(3) **RoHS values:** Yes, No, RoHS Exempt. See the TI RoHS Statement for additional information and value definition.

(4) **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

(5) **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

(6) **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.

**Important Information and Disclaimer:**The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties.
