

BQ25756E: Standalone/I²C Controlled, 1- to 7-Cell Bidirectional Buck-Boost Battery Charge Controller

1 Features

- Wide input voltage operating range: 4.2 V to 36 V
- Wide battery voltage operating range: up-to 36 V with multi-chemistry support:
 - 1- to 7-cell Li-ion charge profile
 - 1- to 9-cell LiFePO₄ charge profile
- Synchronous buck-boost charge controller with NFET drivers
 - Adjustable switching frequency from 200 kHz to 600 kHz
 - Optional synchronization to external clock
 - Integrated loop compensation with soft start
 - Optional gate driver supply input for optimized efficiency
- Automatic maximum power point tracking (MPPT) for solar charging
- Bidirectional converter operation (Reverse Mode) supporting USB-PD Extended Power Range (EPR)
 - Adjustable input voltage (VAC) regulation from 3.3 V to 36 V with 20-mV/step
 - Adjustable input current regulation (R_{AC_SNS}) from 400 mA to 20 A with 50-mA/step using 5-mΩ resistor
- High accuracy
 - ±0.5% charge voltage regulation
 - ±3% charge current regulation
 - ±3% input current regulation
- I²C controlled for optimal system performance with resistor-programmable option
 - Hardware adjustable input and output current limits
- Integrated 16-bit ADC for voltage, current, and temperature monitoring
- High safety integration
 - Adjustable input overvoltage and undervoltage protection
 - Battery overvoltage and overcurrent protection
 - Charging safety timer
 - Battery short protection
 - Thermal shutdown
- Status outputs
 - Adapter present status (PG)
 - Charger operation status (STAT1, STAT2)
- Package
 - 36-pin 5 mm × 6 mm QFN

2 Applications

- Cordless power tool, Garden tool
- Robotic lawn mower
- Portable power station
- Cordless vacuum cleaner, Vacuum robot
- Solar charger

3 Description

The BQ25756E is a wide input voltage, switched-mode buck-boost Li-Ion, Li-polymer, or LiFePO₄ battery charge controller with bidirectional power flow support. The device offers high-efficiency battery charging over a wide voltage range with accurate charge current and charge voltage regulation, in addition to automatic charge preconditioning, termination, and charge status indication. The device integrates all the loop compensation for the buck-boost converter, thereby providing a high density solution with ease of use. In reverse mode, the device draws power from the battery and regulates the input terminal voltage with an added constant current limit for protection, supporting USB-PD EPR power profile.

Package Information

PART NUMBER	PACKAGE ⁽¹⁾	PACKAGE SIZE ⁽²⁾	BODY SIZE (NOM)
BQ25756E	RRV (VQFN 36)	6.0 mm × 5.0 mm	6.0 mm × 5.0 mm

(1) For all available packages, see [Section 14](#).

(2) The package size (length × width) is a nominal value and includes pins, where applicable.

Simplified Schematic

An IMPORTANT NOTICE at the end of this data sheet addresses availability, warranty, changes, use in safety-critical applications, intellectual property matters and other important disclaimers. PRODUCTION DATA.

4 Description (continued)

Besides the I²C host-controlled charging mode, the device also supports standalone charging mode via resistor programmable limits. Input current, charge current and charge voltage regulation targets can be set via the ILIM_HIZ, ICHG and FB pins, respectively.

5 Device Comparison

PART NUMBER	BQ25750	BQ25756E	BQ25756

6 Pin Configuration and Functions

Figure 6-1. BQ25756E, RRV Package 36-pin VQFN Top View

Table 6-1. Pin Functions

PIN		I/O	DESCRIPTION
NAME	NO.		
SCL	1	I	I²C Interface Clock – Connect SCL to the logic rail through a 10-kΩ resistor.
SDA	2	IO	I²C Interface Data – Connect SDA to the logic rail through a 10-kΩ resistor.
INT	3	O	Open Drain Interrupt Output – Connect the INT pin to a logic rail via 10-kΩ resistor. The INT pin sends an active low, 256-μs pulse to host to report the charger device status and faults.
STAT1	4	O	Open Drain Charge Status 1 Output – STAT1 and STAT2 indicate various charger operations, see Table 8-6 . Connect to the pull up rail via 10-kΩ resistor. The STAT1, STAT2 pin functions can be disabled when DIS_STAT_PINS bit is set to 1. When disabled, this pin can be used as a general purpose indicator via the FORCE_STAT1_ON bit.
STAT2	5	O	Open Drain Charge Status 2 Output – STAT1 and STAT2 indicate various charger operations, see Table 8-6 . Connect to the pull up rail via 10-kΩ resistor. The STAT1, STAT2 pin functions can be disabled when DIS_STAT_PINS bit is set to 1. When disabled, this pin can be used as a general purpose indicator via the FORCE_STAT2_ON bit.
PG	6	O	Open Drain Active Low Power Good Indicator – Connect to the pull up rail via 10-kΩ resistor. LOW indicates a good input source if VAC is within the programmed ACUV / ACOV operating window. The PG pin function can be disabled when DIS_PG_PIN bit is set to 1. When disabled, this pin can be used as a general purpose indicator via the FORCE_STAT3_ON bit.
CE	7	IO	Active Low Charge Enable Pin – Battery charging is enabled when EN_CHG bit is 1 and CE pin is LOW. CE pin must be pulled HIGH or LOW, do not leave floating. The CE pin function can be disabled when DIS_CE_PIN bit is set to 1. When disabled, this pin can be used as a general purpose indicator via the FORCE_STAT4_ON bit.

Table 6-1. Pin Functions (continued)

PIN		I/O	DESCRIPTION
NAME	NO.		
TS	8	I	Temperature Qualification Voltage Input – Connect a negative temperature coefficient thermistor. Program temperature window with a resistor divider from REGN to TS to PGND. Charge suspends when TS pin voltage is out of range. Recommend 103AT-2 10-kΩ thermistor.
ICHG	9	I	Charge Current Limit Setting – ICHG pin sets the maximum charge current, and can be used to monitor the charge current. A programming resistor to PGND is used to set the charge current limit as $I_{CHG} = K_{ICHG} / R_{ICHG}$. When the device is under charge current regulation, the voltage at ICHG pin is V_{REF_ICHG} . When ICHG pin voltage is less than V_{REF_ICHG} , the actual charge current can be calculated as: $IBAT = K_{ICHG} \times V_{ICHG} / (R_{ICHG} \times V_{REF_ICHG})$. The actual charge current limit is the lower of the limits set by ICHG pin or the ICHG_REG register bits. This pin function can be disabled when EN_ICHG_PIN bit is 0. If ICHG pin is not used, this pin should be pulled to PGND, do not leave floating.
ILIM_HIZ	10	I	Input Current Limit Setting and HIZ Mode Control Pin – ILIM_HIZ pin sets the maximum input current limit, can be used to monitor the input current and can be pulled HIGH to force device into HIZ mode. A programming resistor to PGND is used to set the input current limit as $I_{ILIM} = K_{ILIM} / R_{ILIM}$. When the device is under input current regulation, the voltage at ILIM_HIZ pin is V_{REF_ILIM} . When ILIM_HIZ pin voltage is less than V_{REF_ILIM} , the actual input current can be calculated as: $IAC = K_{ILIM} \times V_{ILIM} / (R_{ILIM} \times V_{REF_ILIM})$. The actual input current limit is the lower of the limits set by ILIM_HIZ pin or the IAC_DPM register bits. This pin function can be disabled when EN_ILIM_HIZ_PIN bit is 0. If ILIM_HIZ pin is not used, this pin should be pulled to PGND, do not leave floating.
FBG	11	I	Voltage Feedback Divider Return – Connect to the bottom of battery feedback resistor. When charging, this pin is driven to PGND internally. When input voltage is outside of the ACUV / ACOV operating window, this pin is high-impedance, minimizing battery leakage current.
FB	12	I	Charge Voltage Analog Feedback Adjustment – Connect the output of a resistive voltage divider from the battery terminals to this node to adjust the output battery regulation voltage.
SRN	13	I	Charge Current-Sense Resistor, Negative Input – A 0.47-µF ceramic capacitor is placed from SRN to SRP to provide differential-mode filtering. An optional 0.1-µF ceramic capacitor is placed from the SRN pin to PGND for common-mode filtering.
SRP	14	I	Charge Current-Sense Resistor, Positive Input – A 0.47-µF ceramic capacitor is placed from SRN to SRP to provide differential-mode filtering. A 0.1-µF ceramic capacitor is placed from the SRP pin to PGND for common-mode filtering.
NC	15	-	No Connect - Leave this pin floating, do not tie to PGND
NC	16	-	No Connect - Leave this pin floating, do not tie to PGND
PGND	17	-	Tie this pin directly to PGND (Pin 22).
SW2	18	P	Boost Side Half Bridge Switching Node – Connect to the source of boost HS FET and the drain of boost LS FET. Connect the inductor between SW1 and SW2.
HIDRV2	19	O	Boost Side High-Side Gate Driver – Connect to the boost high-side N-channel MOSFET gate.
BTST2	20	P	Boost Side High-Side Power MOSFET Gate Driver Power Supply – Connect a capacitor between BTST2 and SW2 to provide bias to the high-side MOSFET gate driver.
LODRV2	21	O	Boost Side Low-Side Gate Driver – Connect to the boost low-side N-channel MOSFET gate.
PGND	22	P	Power Ground Return – The high current ground connection for the low-side gate drivers.
DRV_SUP	23	P	Charger Gate Drive Supply Input – Voltage on this pin is used to drive the gates of buck-boost converter switching FET. Connect a 4.7-µF ceramic capacitor from DRV_SUP to power ground. REGN LDO voltage can be used as the gate driver supply for all switching FETs by connecting REGN to DRV_SUP pin. In high-voltage applications, it is possible to directly provide the DRV_SUP voltage with an external supply up to 12 V to achieve higher switching efficiency. See Section 8.3.3.2 for more details.
REGN	24	P	Charger Internal Linear Regulator Output – Connect a 4.7-µF ceramic capacitor from REGN to power ground. REGN LDO voltage can be used as the gate driver supply for all switching FETs by connecting REGN to DRV_SUP pin. In high-voltage applications, it is possible to directly provide the DRV_SUP voltage with an external supply up to 12 V to achieve higher switching efficiency. See Section 8.3.3.2 for more details.
LODRV1	25	O	Buck Side Low-Side Gate Driver – Connect to the buck low-side N-channel MOSFET gate.
BTST1	26	P	Buck Side High-Side Power MOSFET Gate Driver Power Supply – Connect a capacitor between BTST1 and SW1 to provide bias to the high-side MOSFET gate driver.
HIDRV1	27	O	Buck Side High-Side Gate Driver – Connect to the buck high-side N-channel MOSFET gate.

Table 6-1. Pin Functions (continued)

PIN		I/O	DESCRIPTION
NAME	NO.		
SW1	28	P	Buck Side Half Bridge Switching Node – Connect to the source of buck HS FET and the drain of buck LS FET. Connect the inductor between SW1 and SW2.
ACN	29	I	Adapter Current-Sense Resistor, Negative Input – A 0.47- μ F ceramic capacitor is placed from ACN to ACP to provide differential-mode filtering. An optional 0.1- μ F ceramic capacitor is placed from the ACN pin to PGND for common-mode filtering.
ACP	30	I	Adapter Current-Sense Resistor, Positive Input – A 0.47- μ F ceramic capacitor is placed from ACN to ACP to provide differential-mode filtering. A 0.1- μ F ceramic capacitor is placed from the ACP pin to PGND for common-mode filtering
NC	31	-	No Connect - Leave this pin floating, do not tie to PGND
VAC	32	P	Input Voltage Detection and Power – Connect a 1- μ F capacitor from pin to PGND. Pin 33 is the input bias to power the IC, and ACOV/ACUV resistor divider should be connected relative to pin 33. When Reverse Mode is enabled, pin 32 is regulated to VAC_REV.
	33		
ACUV	34	I	AC Undervoltage Comparator Input – Connect a resistor divider from VAC to PGND to program the undervoltage protection. When this pin falls below V_{REF_ACUV} , the device stops charging. The hardware limit for input voltage regulation reference is V_{ACUV_DPM} . The actual input voltage regulation is the higher of the pin-programmed value and the VAC_DPM register value. If ACUV programming is not used, pull this pin to VAC, do not leave floating.
ACOV	35	I	AC Overvoltage Comparator Input – Connect a resistor divider from VAC to PGND to program the overvoltage protection. When this pin rises above V_{REF_ACOV} , the device stops charging. If ACOV programming is not used, pull this pin to PGND, do not leave floating.
FSW_SYNC	36	I	Switching Frequency and Synchronization Input – An external resistor is connected to the FSW_SYNC pin and PGND to set the nominal switching frequency. This pin can also be used to synchronize the PWM controller to an external clock with 200-kHz to 600-kHz frequency.
Thermal Pad	37	P	Exposed pad beneath the IC – Always solder the thermal pad to the board, and have vias on the thermal pad plane star-connecting to PGND and ground plane for high-current power converter. It also serves as a thermal pad to dissipate the heat.

7 Specifications

7.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)⁽¹⁾

		MIN	MAX	UNIT
Voltage	VAC, ACUV, ACOV, ACP, ACN, SRP, SRN, FB, FBG	-0.3	60	V
Voltage	SW1, SW2	-2	60	V
Voltage	SW1, SW2 (40ns transient)	-4	60	V
Voltage	PG	-0.3	40	V
Voltage	BTST1, HIDRV1 with respect to SW1	-0.3	14	V
Voltage	BTST2, HIDRV2 with respect to SW2	-0.3	14	V
Voltage	DRV_SUP, LODRV1, LODRV2	-0.3	14	V
Voltage	ACP with respect to ACN, SRP with respect to SRN	-0.3	0.3	V
Voltage	CE, FSW_SYNC, ICHG, ILIM_HIZ, INT, REGN, SCL, SDA, MODE, STAT1, STAT2, TS	-0.3	6	V
Output Sink Current	CE, PG, STAT1, STAT2		5	mA
T _J	Junction temperature	-40	150	°C
T _{stg}	Storage temperature	-65	150	°C

(1) Stresses beyond those listed under *Absolute Maximum Rating* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Condition*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

7.2 ESD Ratings

		VALUE	UNIT
V _(ESD)	Electrostatic discharge	Human body model (HBM), per ANSI/ESDA/JEDEC JS-001, all pins ⁽¹⁾	±2000
		Charged device model (CDM), per ANSI/ESDA/JEDEC JS-002, all pins ⁽²⁾	±500

(1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.

(2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

7.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

		MIN	NOM	MAX	UNIT
V _{AC}	Input voltage	4.2	36	36	V
V _{BAT}	Battery voltage	0	36	36	V
V _{DRV_SUP}	DRV_SUP pin direct drive voltage range	4.0	12	12	V
F _{SW}	Switching Frequency	200	600	600	kHz
T _J	Junction temperature	-40	125	125	°C
T _A	Ambient temperature	-40	105	105	°C
C _{VAC}	VAC capacitor	1			μF
C _{IN}	Buck-boost input capacitance (minimum value after derating)	160			μF
C _{OUT}	Buck-boost output capacitance (minimum value after derating)	160			μF
C _{REGN}	REGN capacitor (nominal value before derating)	4.7			μF
C _{DRV_SUP}	DRV_SUP capacitor (nominal value before derating)	4.7			μF
L	Switched Inductor	2.2		15	μH
R _{DCR}	Inductor DC resistance	1.75		60	mΩ

7.3 Recommended Operating Conditions (continued)

over operating free-air temperature range (unless otherwise noted)

		MIN	NOM	MAX	UNIT
R _{AC_SNS}	Input current sense resistor	0 ⁽¹⁾	5	10	mΩ
R _{BAT_SNS}	Battery current sense resistor		5		mΩ
R _{ICHG}	ICHG programming pulldown resistor	0.0 ⁽²⁾		100	kΩ
R _{ILIM_HIZ}	ILIM_HIZ programming pulldown resistor	0.0 ⁽³⁾		50	kΩ

- (1) When R_{AC_SNS} is 0mΩ, input current limit function is disabled
- (2) When R_{ICHG} is pulled to GND, the hardware charge current limit is disabled, actual charge current is controlled by the ICHG_REG register setting
- (3) When R_{ILIM_HIZ} is pulled to GND, the hardware input current limit is disabled, actual input current is controlled by the IAC_DPM register setting

7.4 Thermal Information

THERMAL METRIC ⁽¹⁾		BQ25756E	UNIT
		RRV	
		36 PINS	
R _{θJA}	Junction-to-ambient thermal resistance (JEDEC ⁽¹⁾)	29.4	°C/W
R _{θJC(top)}	Junction-to-case (top) thermal resistance	18.8	°C/W
R _{θJB}	Junction-to-board thermal resistance	9.9	°C/W
Ψ _{JT}	Junction-to-top characterization parameter	0.2	°C/W
Ψ _{JB}	Junction-to-board characterization parameter	9.8	°C/W
R _{θJC(bot)}	Junction-to-case (bottom) thermal resistance	2.5	°C/W

- (1) For more information about traditional and new thermal metrics, see the [Semiconductor and IC Package Thermal Metrics application report](#).

7.5 Electrical Characteristics

V_{AC} = ACP = ACN = SYS = SRP = SRN = 28V, T_J = -40°C to +125°C, and T_J = 25°C for typical values (unless otherwise noted)

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
QUIESCENT CURRENTS						
I _{Q_BAT}	Quiescent battery current with BATFET on (I _{SRN} + I _{SRP})	V _{BAT} = 28V, V _{AC} = 0V, ADC_EN = 0, T _J < 105 °C		17		μA
		V _{BAT} = 28V, V _{AC} = 0V, ADC_EN = 1, T _J < 105 °C		500	700	μA
I _{Q_VAC}	Quiescent input current (I _{VAC})	Not switching	0.75	1	1	mA
I _{Q_REV}	Quiescent battery current in Reverse mode (I _{SRN} + I _{SRP})	Not switching	0.75	1	1	mA
VAC / BAT POWER UP						
V _{VAC_OP}	VAC operating range		4.2	36		V
V _{VAC_OK}	VAC converter enable threshold	VAC rising, no battery	4.2			V
V _{VAC_OKZ}	VAC converter disable threshold	VAC falling, no battery		3.5		V
V _{REF_ACUV}	ACUV comparator threshold to enter VAC_UVP	V _{ACUV} falling	1.095	1.1	1.106	V
V _{REF_ACUV_HYS}	ACUV comparator threshold hysteresis	V _{ACUV} rising	50			mV
V _{VAC_INT_OV}	VAC internal threshold to enter VAC_OVP	IN rising	36			V
V _{VAC_INT_OVZ}	VAC internal thresholds to exit VAC_OVP	IN falling	33			V
V _{REF_ACOV}	ACOV comparator threshold to enter VAC_OVP	V _{ACOV} rising	1.184	1.2	1.206	V
V _{REF_ACOV_HYS}	ACOV comparator threshold hysteresis	V _{ACOV} falling	50			mV
CHARGE VOLTAGE REGULATION						
V _{VFB_RANGE}	Feedback voltage range		1.504	1.566		V
V _{VFB_STEP}	Typical feedback voltage step		2			mV
V _{VFB_NOM}	Nominal feedback voltage	V _{VFB_REG} = 0x10	1.536			V
V _{VFB_ACC}	Feedback voltage regulation accuracy	T _J = 0°C to 85°C	-0.5	0.5		%
		T _J = -40°C to 125°C	-0.7	0.7		%
R _{FBG}	FBG resistance to PGND	I _{FBG} = 1mA	33	55		Ω
FAST CHARGE CURRENT REGULATION						
I _{CHG_REG_RANGE}	Charge current regulation range		0.4	20		A
I _{CHG_REG_STEP}	Charge current regulation step		50			mA
I _{CHG_REG_ACC}	I ² C setting charge current regulation accuracy	R _{BAT_SNS} = 5mΩ, V _{BAT} = 12V, 36V. ICHG_REG = 0x012C	15			A
			-3	3		%
		R _{BAT_SNS} = 5mΩ, V _{BAT} = 12V, 36V. ICHG_REG = 0x0064	5			A
			-3	3		%
		R _{BAT_SNS} = 5mΩ, V _{BAT} = 12V, 36V. ICHG_REG = 0x0028	2			A
			-5	5		%
K _{ICHG}	Hardware charge current limit set factor (Amperes of charge current per kΩ on ICHG pin)	R _{BAT_SNS} = 5mΩ, R _{ICHG} = 10kΩ, 5kΩ, and 3.33kΩ	48	50	52	A x kΩ
V _{REF_ICHG}	ICHG pin voltage when ICHG pin is in regulation		2.0			V
PRE-CHARGE CURRENT REGULATION						

7.5 Electrical Characteristics (continued)

VAC = ACP = ACN = SYS = SRP = SRN = 28V, $T_J = -40^{\circ}\text{C}$ to $+125^{\circ}\text{C}$, and $T_J = 25^{\circ}\text{C}$ for typical values (unless otherwise noted)

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
I_{BAT_SHORT}	Trickle charge current accuracy for Li-Ion batteries	$V_{FB} < V_{BAT_SHORT}$		150		mA

8 Detailed Description

8.1 Overview

The BQ25756E is a wide input voltage, Li-Ion, Li-polymer, LiFePO₄ bi-directional switched-mode buck-boost battery charge controller. The device offers high-efficiency battery charging over a wide voltage range with accurate and programmable charge current and charge voltage regulation, in addition to automatic charge preconditioning, termination, and charge status indication. The device integrates all the loop compensation and 5-V gate drivers for the buck-boost converter, thereby providing a high density solution with ease of use. The switching frequency of the device can be programmed or forced to follow an external clock frequency via the FSW_SYNC pin. While switching under light-load the device offers an optional Pulse Frequency Modulation (PFM) mode to increase efficiency. The charger has a digital state machine that advances the charger's states as the converter analog feedback loops hand off control to each other. It also manages the fault protection comparators. The loops regulate and comparators compare against reference values in the I²C registers, unless clamped by external resistors.

Besides the I²C host-controlled charging mode, the device also supports autonomous charging mode via resistor programmable limits. Input current, charge current and charge voltage regulation targets can be changed via the ILIM_HIZ, ICHG, and FB pins, respectively. The device can complete a charging cycle without any software intervention. Charging function is controlled via the \overline{CE} pin.

For Li-Ion and LiFePO₄ chemistries, the device checks battery voltage and charges the battery in different phases accordingly: trickle charging, pre-charging, constant current (CC) charging and constant voltage (CV) charging. At the end of the charging cycle, the charger automatically terminates when the charge current is below the termination current limit in the constant voltage phase. When the full battery falls below the recharge threshold, the charger automatically starts a new charge cycle.

The input operating window is programmed via the ACUV and ACOV pins. When the input voltage is outside the programmed window, the device automatically stops the charger, and the \overline{PG} pin pulls HIGH.

The charger provides various safety features for battery charging and system operation, including battery temperature negative thermistor (NTC) monitoring, charge timers and over-voltage/over-current protections on battery and input. The thermal shutdown prevents charging when the junction temperature exceeds the T_{SHUT} limit.

The device supports buck-boost reverse power direction to deliver power from the battery to the input when the adapter is not present. In reverse mode, the regulation voltage and current can be programmed via the I²C interface (VAC_REV and IAC_REV) to provide a CC/CV profile supporting the USB-PD Extended Power Range (EPR).

The device has three status pins (STAT1, STAT2, and \overline{PG}) to indicate the charging status and input voltage status. These pins can be used to drive LEDs or communicate with a host processor. If needed, these pins can also be used as general purpose indicators and their status controlled directly by the I²C interface. In addition, the \overline{CE} pin can also be used as a general purpose indicator. The \overline{INT} pin immediately notifies host when the device status changes, including faults.

The device also provides a 16-bit analog-to-digital converter (ADC) for monitoring input current, charge current and input/battery/thermistor voltages (IAC, IBAT, VAC, VBAT, TS).

The device comes with a 36-pin 5-mm × 6-mm QFN package with 0.5-mm pin pitch.

8.2 Functional Block Diagram

8.3 Feature Description

8.3.1 Device Power-On-Reset

The internal bias circuits are powered from either VAC or SRN. When VAC rises above V_{VAC_OK} , charging is allowed. When BAT rises above 3 V, reverse mode operation is allowed.

A POR occurs when one of these supplies rises above its corresponding V_{OK} level, while the other supply is below its corresponding V_{OK} level. After the POR, I²C interface is ready for communication and all the registers are reset to default value. The host can access all the registers after POR.

8.3.2 Device Power-Up From Battery Without Input Source

If only battery is present and the voltage is above 3-V threshold, the device is ready for I²C communication , and the converter is ready to start operation in reverse mode. The REGN LDO stays off to minimize the quiescent current. The ADC can be used to monitor all system parameters.

8.3.3 Device Power Up from Input Source

When a valid input source ($V_{VAC_OK} < VAC$ and VAC within the ACUV and ACOV operating window) is detected, the \overline{PG} pin pulls LOW. If charging is enabled, the device proceeds to enable the REGN LDO and power up the buck-boost converter.

8.3.3.1 VAC Operating Window Programming (ACUV and ACOV)

The VAC operating window can be programmed via the ACUV and ACOV pins using a three-resistor divider from VAC to PGND as shown in [Figure 8-1](#).

Figure 8-1. ACUV and ACOV Programming

When V_{ACUV} falls and reaches V_{ACUV_DPM} , the device enters input voltage regulation, thereby reducing the charge current. V_{ACUV} continues falling below V_{REF_ACUV} , the device automatically stops the converter and the \overline{PG} pin pulls high.

System Note: if VAC_DPM register is programmed to a value higher than POR, the device regulates the VAC voltage to the higher of VAC_DPM register or V_{ACUV_DPM} pin voltage. Refer to [Section 8.3.5.1.2](#) for more information.

When V_{ACOV} rises above V_{REF_ACOV} , the device automatically stops the converter and the \overline{PG} pin pulls high.

The following equations govern the relationship between the resistor divider and the target operating voltage window programmed by ACOV and ACUV pins:

$$V_{ACOV_TARGET} = V_{REF_ACOV} \times \frac{R_{AC1} + R_{AC2} + R_{AC3}}{R_{AC3}} \quad (1)$$

$$V_{ACUV_TARGET} = V_{REF_ACUV} \times \frac{R_{AC1} + R_{AC2} + R_{AC3}}{R_{AC2} + R_{AC3}} \quad (2)$$

If unused, tie ACUV to VAC and ACOV to PGND in order to apply the internal VAC operating window (V_{VAC_OP}).

8.3.3.2 REGN Regulator (REGN LDO)

The REGN LDO regulator provides a regulated bias supply for the IC and the TS external resistors. Additionally, REGN voltage can be used to drive the buck-boost switching FETs directly by tying the DRV_SUP pin to REGN. The pull-up rail of PG, STAT1, and STAT2 can be connected to REGN as well. The REGN LDO is enabled when below conditions are valid:

1. VAC voltage above V_{VAC_OK} and charge is enabled in forward mode.
2. BAT voltage above 3 V in Reverse mode and Reverse Mode is enabled ($EN_REV = 1$)

At high input voltages and/or large gate drive requirements, the power loss from gate driving via the REGN LDO can be excessive. This power for the gate drivers can be provided externally by directly driving the DRV_SUP pin with a high efficiency supply ranging from 4.5 V to 12 V. This supply should be able to provide at least 50 mA or more as required to drive the switching FET gate charge.

The power dissipation for driving the gates via the REGN LDO is: $P_{REGN} = (V_{AC} - V_{REGN}) \times Q_{G(TOT)1,2,3,4} \times f_{SW}$, where $Q_{G(TOT)1,2,3,4}$ is the sum of the total gate charge for all switching FETs and f_{SW} is the programmed switching frequency. The Safe Operating Area (SOA) below is based on a 1-W power loss limit.

Figure 8-2. REGN LDO Safe Operating Area (SOA)

8.3.3.3 Compensation-Free Buck-Boost Converter Operation

The device integrates all the loop compensation, thereby providing a high density solution with ease of use. At startup, the device toggles the SW node for about 40 ms to determine the correct compensation values for a given set of passives. If the battery is above $VBAT_LOWV$, then SW2 is toggled. SW1 is toggled otherwise.

The charger employs a synchronous buck-boost converter that allows charging from a wide range of input voltage sources. The charger operates in buck, buck-boost or boost mode. The converter can operate uninterruptedly and continuously across the three operation modes. During buck-boost mode, the converter alternates a SW1 pulse with a SW2 pulse, with effective switching frequency interleaved among these pulses for highest efficiency operation.

During boost mode operation, the HS FET is forced to turn on for 225 ns in each switching cycle to ensure inductor energy is delivered to the output, effectively limiting the maximum boosting ratio. For example, when device is configured to switch at 500 kHz, the switching period is 2 μ s, yielding a duty cycle limit of $(1 - 0.225 \mu\text{s}/2 \mu\text{s}) = 88.75\%$. Given a 5-V input, this translates to a maximum 44-V output assuming 100% efficiency. The true output will be lower than this ideal limit. At lower switching frequencies, the maximum duty cycle increases, making the limitation less significant.

Table 8-1. Switching MOSFET Operation

MODE	BUCK	BUCK-BOOST	BOOST
HS BUCK FET	Switching at f_{SW}	Switching (f_{SW} interleaved between SW1 and SW2)	ON
LS BUCK FET	Switching at f_{SW}	Switching (f_{SW} interleaved between SW1 and SW2)	OFF
LS BOOST FET	OFF	Switching (f_{SW} interleaved between SW1 and SW2)	Switching at f_{SW}
HS BOOST FET	ON	Switching (f_{SW} interleaved between SW1 and SW2)	Switching at f_{SW}

8.3.3.3.1 Light-Load Operation

In order to improve converter light-load efficiency, the device switches to Pulse Frequency Modulation (PFM) control at light load when the EN_PFM bit is set to 1. The effective switching frequency will decrease accordingly when output load decreases.

EN_PFM bit is automatically cleared to 0 every time the converter starts and a valid SYNC clock input is detected on the FSW_SYNC pin, thereby ensuring fixed frequency operation regardless of output current. The bit can be overwritten to 1 to allow PFM after startup even when SYNC signal is present.

Light-load PFM mode can be disabled by clearing the EN_PFM bit. In this case, the device switches in PWM mode at a fixed switching frequency. It is recommended to disable PFM mode (EN_PFM = 0) when termination is enabled and set lower than 2 A.

8.3.3.4 Switching Frequency and Synchronization (FSW_SYNC)

The device switching frequency can be programmed between 200 kHz to 600 kHz using a resistor from the FSW_SYNC pin to PGND. The R_{FSW} resistor is related to the nominal switching frequency (f_{SW}) by the equation:

$$R_{FSW} = \frac{1}{10 \times (f_{SW} \times 5 \times 10^{-12} - 500 \times 10^{-9})} \quad (3)$$

This pin must be pulled to PGND using a R_{FSW} , do not leave floating. In addition to programming the nominal switching frequency, the FSW_SYNC pin can also be used to synchronize the internal oscillator to an external clock signal. The synchronization feature works over the same range as the switching frequency: 200-kHz to 600-kHz range.

Table 8-2. Common R_{FSW} and Switching Frequency Values

R_{FSW} (kΩ)	SWITCHING FREQUENCY (kHz)
200	200
133	250
100	300
80	350
66.67	400
57.1	450
50	500
44.4	550
40	600

8.3.3.5 Device HIZ Mode

When a valid input supply is present, it is possible to force the device into HIZ Mode which disables switching, disables REGN LDO. The system load is provided by the battery in this mode. The charger enters HIZ Mode when EN_HIZ bit is set to 1 or the ILIM_HIZ pin is pulled above $V_{IH_ILIM_HIZ}$ (refer to [Section 8.3.5.1.1.1](#)).

If the device is operating in reverse mode with the converter turned on, and the device enters HIZ mode (EN_HIZ bit is set to 1 or ILIM_HIZ pin is pulled above $V_{IH_ILIM_HIZ}$), switching stops. Once HIZ mode condition is cleared by the host, the device resumes reverse mode operation.

The device exits HIZ Mode when the EN_HIZ bit is cleared to 0 and the ILIM_HIZ pin is pulled below 0.4 V.

8.3.4 Battery Charging Management

The device charges 1-cell up-to 14-cell Li-Ion batteries and 1-cell up-to 16-cell LiFePO₄ batteries. The charge cycle is autonomous and requires no host interaction.

8.3.4.1 Autonomous Charging Cycle

When battery charging is enabled (EN_CHG bit =1 and \overline{CE} pin is LOW), the device autonomously completes a charging cycle without host involvement. The device charging parameters can be set by hardware through the FB pin to set regulation voltage and the ICHG pin to set charging current. The host can always control the charging operation and optimize the charging parameters by writing to the corresponding registers through I²C.

Table 8-3. Li-Ion & LiFePO₄ Charging Parameter Default Settings

PARAMETER	VALUE
Charge Stages	Precharge → Fast Charge (CC) → Taper Charge (CV) → Termination → Recharge
FB Voltage Regulation Target (VFB_REG)	1.536 V
Battery Low Voltage (VBAT_LO WV)	66.7% × VFB_REG = 1.0245 V
Recharge Voltage (VRECHG)	97.6% × VFB_REG = 1.4991 V
Charging Current HW Limit (ICHG pin)	$ICHG = K_{ICHG} / R_{ICHG}$
Pre-Charge Current HW Limit (ICHG pin)	20% × ICHG
Termination Current HW Limit (ICHG pin)	10% × ICHG
CV Timer	Disabled
NTC Temperature Profile	JEITA
Safety Timer	12 hours

A new charge cycle starts when the following conditions are valid:

- VAC is within the ACUV and ACOV operating window
- Device is not in HIZ mode ($EN_HIZ = 0$ and ILIM_HIZ pin voltage is below $V_{IH_ILIM_HIZ}$)
- REGN is above V_{REGN_OK}
- Battery charging is enabled ($EN_CHG = 1$ and \overline{CE} pin is LOW)
- No thermistor fault on TS
- No safety timer fault

For lithium-ion battery charging, the charger device automatically terminates the charging cycle when the charging current is below termination threshold, charge voltage is above recharge threshold, and device is not in DPM mode. When a full battery voltage is discharged below recharge threshold (threshold selectable via VRECHG[1:0] bits), the device automatically starts a new charging cycle. After the charge is done, toggle either \overline{CE} pin or EN_CHG bit can initiate a new charging cycle. In addition, the device offers a dedicated CV timer to stop the charging after a programmable period (CV_TMR bits) in CV mode, regardless of the charge current value.

The status register (CHARGE_STAT) indicates the different charging phases as:

- 000 – Not Charging
- 001 – Trickle Charge ($V_{FB} < V_{BAT_SHORT}$)
- 010 – Pre-charge ($V_{BAT_SHORT} < V_{FB} < V_{BAT_LOWV}$)
- 011 – Fast-charge (CC mode)
- 100 – Taper Charge (CV mode)
- 101 – Reserved

- 110 – Top-off Timer Active Charging
- 111 – Charge Termination Done

When the charger transitions to any of these states, including when charge cycle is completed, an INT pulse is asserted to notify the host.

Supercapacitors do not require Trickle Charge or Pre-charge regions when their voltage is low. For supercapacitor charging, setting the EN_PRECHG bit to 0 can disable both of these charging regions. In this case, the charger outputs ICHG current as long as the feedback voltage (V_{FB}) is below V_{FB_REG} . The following settings are recommended for supercapacitor charging:

- EN_PRECHG = 0
- EN_TERM = 0
- EN_CHG_TMR = 0

8.3.4.1.1 Charge Current Programming (ICHG pin and ICHG_REG)

There are two distinct thresholds to limit the charge current (if both are enabled, the lowest limit of these will apply):

1. ICHG pin pull down resistor (hardware control)
2. ICHG_REG register bits (host software control)

To set the maximum charge current using the ICHG pin, a pull-down resistor to PGND is used. It is required to use a 5-mΩ R_{BAT_SNS} sense resistor. The charge current limit is controlled by:

$$I_{CHG_MAX} = \frac{K_{ICHG}}{R_{ICHG}} \quad (4)$$

The precharge current limit is defined as $I_{PRECHG_MAX} = 20\% \times I_{CHG_MAX}$, and the termination current is $I_{TERM} = 10\% \times I_{CHG_MAX}$.

The actual charge current limit is the lower value between ICHG pin setting and I²C register setting (ICHG_REG). For example, if the register setting is 10 A (0xC8), and ICHG pin has a 10-kΩ resistor ($K_{ICHG} = 50$ A-kΩ) to ground for 5 A, the actual charge current limit is 5 A. The device regulates ICHG pin at V_{REF_ICHG} . If ICHG pin voltage exceeds V_{REF_ICHG} , the device enters charge current regulation.

The ICHG pin can also be used to monitor charge current when device is not in charge current regulation. When not in charge current regulation, the voltage on ICHG pin (V_{ICHG}) is proportional to the actual charging current. ICHG pin can be used to monitor battery current with the following relationship:

$$I_{BAT} = \frac{K_{ICHG} \times V_{ICHG}}{R_{ICHG} \times V_{REF_ICHG}} \quad (5)$$

For example, if ICHG pin is set with 10-kΩ resistor, and the ICHG voltage 1.0V, the actual charge current is between 2.4 A to 2.6 A (based on K_{ICHG} specified).

If ICHG pin is shorted to PGND, the charge current limit is set by the ICHG_REG register. If hardware charge current limit function is not needed, it is recommended to short this pin to PGND. The ICHG pin function can be disabled by setting the EN_ICHG_PIN bit to 0 (recommended when pin is shorted to PGND). When the pin is disabled, charge current limit and monitoring functions via ICHG pin are not available.

To set the maximum charge current using the ICHG_REG register bits, write to the ICHG_REG register bits. The charge current limit range is from 400 mA to 20,000 mA with 50 mA/step. The default ICHG_REG is set to maximum code, allowing ICHG pin to limit the current in hardware.

8.3.4.2 Li-Ion Battery Charging Profile

The device charges the battery in five phases: trickle charge, pre-charge, constant current, constant voltage, and top-off trickle charging (optional). At the beginning of a charging cycle, the device checks the battery voltage and regulates current/voltage accordingly.

Table 8-4. Recommended Li-Ion Charge Settings

PARAMETER	I ² C REGISTER BITS	VALUE	EQUIVALENT PER 4.2-V CHARGE (V)
Battery Low Voltage	VBAT_LOWV	$0x3 = 71.4\% \times V_{FB_REG}$	3.0 V
Recharge Voltage	VRECHG	$0x3 = 97.6\% \times V_{FB_REG}$	4.1 V

If the charger device is in DPM regulation during charging, the actual charging current will be less than the programmed value. In this case, termination is temporarily disabled and the charging safety timer is counted at half the clock rate, as explained in Charging Safety Timer.

Figure 8-3. Typical Li-Ion Battery Charging Profile

8.3.4.3 LiFePO₄ Battery Charging Profile

The device charges the battery in five phases: trickle charge, pre-charge, constant current, constant voltage, and top-off trickle charging (optional). At the beginning of a charging cycle, the device checks the battery voltage and regulates current/voltage accordingly.

Table 8-5. Recommended LiFePO₄ Charge Settings

PARAMETER	I ² C REGISTER BITS	VALUE	EQUIVALENT PER 3.6-V CHARGE (V)
Battery Low Voltage	VBAT_LOWV	$0x1 = 55\% \times V_{FB_REG}$	1.98 V
Recharge Voltage	VRECHG	$0x0 = 93\% \times V_{FB_REG}$	3.35 V

If the charger device is in DPM regulation during charging, the actual charging current will be less than the programmed value. In this case, termination is temporarily disabled and the charging safety timer is counted at half the clock rate, as explained in Charging Safety Timer. The typical charging cycle for LiFePO₄ follows the same profile as [Typical Li-Ion Battery Charging Profile](#).

8.3.4.4 Charging Termination for Li-ion and LiFePO₄

The device terminates a charge cycle when the battery voltage is above recharge threshold, and the current is below termination current. The termination current threshold is controlled by the lower option between 10% x ICHG pin setting or the ITERM register setting.

In standalone applications using the ICHG pin to program the current, the termination threshold is set at 10% of the ICHG pin value (10-A ICHG pin programming results in 1-A termination).

In host-controlled applications, the termination current can be programmed using the ITERM register bits. The ICHG pin can still be used to set a hardware limit for the charge current.

After the charging cycle is completed, the buck-boost converter turns off. When termination occurs, the status register CHARGE_STAT is set to 111, and an INT pulse is asserted to the host. Termination is temporarily disabled when the charger device is in input current, or input voltage regulation. Termination can be permanently disabled by writing 0 to EN_TERM.

At low termination currents, due to the comparator offset, the actual termination current may be up to 20% higher than the termination target. In order to compensate for comparator offset, a programmable top-off timer (default disabled) can be applied after termination is detected. The top-off timer follows safety timer constraints, such that if safety timer is suspended, so is the top-off timer. Similarly, if safety timer is doubled, so is the top-off timer. CHARGE_STAT reports whether the top off timer is active via the 110 code. Once the Top-Off timer expires, the CHARGE_STAT register is set to 111 and an INT pulse is asserted to the host.

8.3.4.5 Charging Safety Timer

The device has built-in safety timer to prevent extended charging cycle due to abnormal battery conditions. The user can program fast charge safety timer through I²C (CHG_TMR bits). When safety timer expires, the fault register CHG_TMR_STAT bit is set to 1, and an INT pulse is asserted to the host. The safety timer feature can be disabled by clearing EN_CHG_TMR bit.

During input voltage or input current regulation, the safety timer counts at half clock rate as the actual charge current is likely to be below the programmed setting. For example, if the charger is in input current regulation (IAC_DPM_STAT=1) throughout the whole charging cycle, and the safety timer is set to 5 hours, then the timer will expire in 10 hours. The timer also counts at half clock rate for TS pin events which reduce charge current (refer to [JEITA Guideline Compliance in Charge Mode](#) section). This half clock rate feature can be disabled by setting EN_TMR2X = 0.

During faults which disable charging, timer is suspended. Once the fault goes away, safety timer resumes. If the charging cycle is stopped and started again, the timer gets reset (toggle CE pin or EN_CHG bit restarts the timer).

The pre-charge safety timer is a fixed 2 hour counter that runs when VBAT < V_{BAT_LOW}. The pre-charge safety timer is disabled when EN_PRECHG bit is 0.

8.3.4.6 CV Timer

In some applications, such as batteries with high-leakage or batteries in parallel with a system load, the battery current may never reach the ITERM threshold while in CV mode. The device offers a dedicated CV timer to control the amount of time the charger stays in CV mode.

The CV timer begins counting when the device enters the CV mode , and its duration can be programmed through the CV_TMR register bits. Note that CV_TMR = 0 disables the timer altogether. The CV timer is an absolute timer, and the EN_TMR2X register bit has no effect on it.

During faults which disable charging or when device falls out of CV regulation due to IAC_DPM or VAC_DPM, the CV timer is suspended. Once the device return to CV mode, the CV timer resumes. If the charging cycle is stopped and started again, the timer gets reset (toggle CE pin or EN_CHG bit restarts the timer).

An INT is asserted to the host when CV timer expires, and can be masked via the CV_TMR_MASK bit.

8.3.4.7 Thermistor Qualification

The charger device provides a single thermistor input for battery temperature monitor.

8.3.4.7.1 JEITA Guideline Compliance in Charge Mode

To improve the safety of charging Li-ion batteries, JEITA guideline was released on April 20, 2007. The guideline emphasized the importance of avoiding a high charge current and high charge voltage at certain low and high temperature ranges.

To initiate a charge cycle, the voltage on TS pin must be within the VT1 to VT5 thresholds. If TS voltage exceeds the T1 to T5 range, the controller suspends charging and waits until the battery temperature is within the T1 to T5 range.

At cool temperature, T1 to T2, JEITA recommends the charge current to be reduced to half of the charge current or lower. The device allows charge current in the cool temperature region to be programmed to 20%, 40% or 100% of the charge current at T2 to T3 or charge suspend, which is controlled by the register bits JEITA_ISETC. If charge current is reduced in the cool temperature region, the safety timer counts at half clock rate when EN_TMR2X = 1.

At warm temperature, T3 to T5, JEITA recommends charge voltage less than 4.1 V / cell. The device provides the programmability of the charge voltage at T3-T5, to be with a voltage offset less than charge voltage at T2 to T3 or charge suspend, which is controlled by the register bits JEITA_VSET.

The charger also provides flexible voltage/current settings beyond the JEITA requirements. The charge current setting at warm temperature T3 to T5 can be configured to be 40%, or 100% of the programmed charge current or charge suspend, which is programmed by the register bit JEITA_ISETH. If charge current is reduced in the JEITA warm region, the safety timer counts at half clock rate when EN_TMR2X = 1.

The default charging profile for JEITA is shown in the figure below, in which the blue line is the default setting and the red dash line is the programmable options.

Figure 8-4. TS Charging Values

Assuming a 103AT NTC thermistor on the battery pack as shown above, the value of RT1 and RT2 can be determined by:

$$RT2 = \frac{RTH_{COLD} \times RTH_{HOT} \times \left(\frac{1}{VT1} - \frac{1}{VT5} \right)}{RTH_{HOT} \times \left(\frac{1}{VT5} - 1 \right) - RTH_{COLD} \times \left(\frac{1}{VT1} - 1 \right)} \quad (6)$$

$$RT1 = \frac{\frac{1}{VT1} - 1}{\frac{1}{RT2} + \frac{1}{RTH_{COLD}}} \quad (7)$$

Select 0°C to 60°C range for Li-ion or Li-polymer battery:

$$RTH_{T1} = 27.28 \text{ k}\Omega$$

$$RTH_{T5} = 3.02 \text{ k}\Omega$$

$$RT1 = 5.24 \text{ k}\Omega$$

$$RT2 = 30.31 \text{ k}\Omega$$

The device also offers programmability for all the thresholds via the TS Charging Threshold Control register (REG0x1B). This flexibility can help to change the charger's operating window in software.

The JEITA profile can be disabled by clearing the EN_JEITA register bit. In this case, the device still limits the charging window from T1 to T5, but no special charge profile is employed within the Cool (T1 to T2) or Warm (T3 to T5) regions.

The NTC monitoring window can be disabled by clearing the EN_TS register bit. In this case, the TS pin voltage is ignored, and the device always reports normal TS status. If EN_TS is set to 0, TS pin can be floated or connected to PGND.

8.3.4.7.2 Cold/Hot Temperature Window in Reverse Mode

For battery protection during reverse or auto-reverse mode operation, the device monitors the battery temperature to be within the VBCOLD to VBHOT thresholds. When temperature is outside of the thresholds, the reverse mode is shut off. In addition, EN_REV, EN_AUTO_REV and REVERSE_STAT bits are cleared to 0 and corresponding TS_STAT is reported (TS Cold or TS Hot). The temperature protection in reverse mode can be completely disabled by clearing the EN_TS bit to 0.

Figure 8-5. TS Pin Thermistor Sense Threshold in Reverse Mode

8.3.5 Power Management

The device accommodates a wide range of input sources from 4.2 V up to 36 V.

8.3.5.1 Dynamic Power Management: Input Voltage and Input Current Regulation

The device features Dynamic Power Management (DPM), which continuously monitors the input current and input voltage. When input source is over-loaded, either the current exceeds the input current limit (lower of

IAC_DPM or ILIM_HIZ pin setting), or the voltage falls below the input voltage limit (higher of VAC_DPM or ACUV pin setting, V_{ACUV_DPM}). The device then reduces the charge current until the input current falls below the input current limit and the input voltage rises above the input voltage limit.

When the charge current is reduced to zero, but the input source is still overloaded, the input voltage continues to drop. Once the input voltage drops below the ACUV limit ($V_{ACUV} < V_{REF_ACUV}$), the charger stops switching.

8.3.5.1.1 Input Current Regulation

The total input current is a function of the system supply current and the battery charging current. System current normally fluctuates as portions of the systems are powered up or down. Without DPM, the source must be able to supply the maximum system current and the maximum charger input current simultaneously. By using DPM, the battery charger reduces the charging current when the input current exceeds the input current limit set by the lower of IAC_DPM register bits, or ILIM_HIZ pin. This allows the current capability of the input source to be lowered, reducing system cost.

There are two thresholds to limit the input current (if both are enabled, the lower limit of these two will apply):

1. IAC_DPM register bits (host software control)
2. ILIM_HIZ pull down resistor (hardware control)

To set the maximum current using the IAC_DPM register bits, write to the IAC_DPM register bits. When using a 2-mΩ resistor, the input current limit range is from 1 A to 50 A with 125 mA/step. The default IAC_DPM is set to maximum code, allowing ILIM_HIZ pin to limit the current in hardware.

To set the maximum current using the ILIM_HIZ pin, refer to [Section 8.3.5.1.1.1](#).

Although both limits are referenced to a 2-mΩ sense resistor, other values can also be used. A larger sense resistor provides a larger sense voltage and higher regulation accuracy, but at the expense of higher conduction loss. For example, using a 5-mΩ resistor yields programmability from 400 mA to 20 A with 50 mA/step.

8.3.5.1.1.1 ILIM_HIZ Pin

To set the maximum input current using the ILIM_HIZ pin, a pull-down resistor to PGND is used. When using a 2-mΩ R_{AC_SNS} resistor, the input current limit is controlled by: $I_{AC_MAX} = K_{ILIM} / R_{ILIM_HIZ}$.

The actual input current limit is the lower value between ILIM_HIZ pin setting and register setting (IAC_DPM). For example, if the register setting is 20 A, and ILIM_HIZ pin has a 5-kΩ resistor ($K_{ILIM} = 50 \text{ A}\cdot\text{k}\Omega$) to ground for 10 A, the actual input current limit is 10 A. ILIM_HIZ pin can be used to set the input current limit when EN_ILIM_HIZ_PIN bit is set to 1. The device regulates the pin at $V_{REF_ILIM_HIZ}$. If pin voltage exceeds $V_{REF_ILIM_HIZ}$, the device enters input current regulation. Entering input current regulation through the pin sets the IAC_DPM_STAT and FLAG bits, and produces an interrupt to host. The interrupt can be masked via the IAC_DPM_MASK bit.

The ILIM_HIZ pin can also be used to monitor input current. When not in input current regulation, the voltage on ILIM_HIZ pin (V_{ILIM_HIZ}) is proportional to the input current. Pin voltage can be used to monitor input current with the following relationship: $IAC = K_{ILIM} \times V_{ILIM_HIZ} / (R_{ILIM_HIZ} \times V_{REF_ILIM_HIZ})$.

For example, if the pin is set with 5-kΩ resistor, and the pin voltage is 1.0 V, the actual input current is between 4.8 A to 5.2 A (based on K_{ILIM} specified).

If ILIM_HIZ pin is shorted, the input current limit is set by the IAC_DPM register. If hardware input current limit function is not needed, it is recommended to short this pin to GND. If ILIM_HIZ pin is pulled above $V_{IH_ILIM_HIZ}$, the device enters HIZ mode (refer to [Section 8.3.3.5](#)). The ILIM_HIZ pin function can be disabled by setting the EN_ILIM_HIZ_PIN bit to 0. When the pin is disabled, input current limit and monitoring functions as well as HIZ mode control via the pin are not available.

K_{ILIM} is defined as $50 \text{ A}\cdot\text{k}\Omega$ referenced to a 2-mΩ sense resistor. A larger sense resistor provides a larger sense voltage and higher regulation accuracy, but changes the gain from the ILIM_HIZ pin. For example, using a 5-mΩ resistor yields $K_{ILIM} = 50 (\text{A}\cdot\text{k}\Omega) \times 2 (\text{m}\Omega) / 5 (\text{m}\Omega) = 20 (\text{A}\cdot\text{k}\Omega)$.

8.3.5.1.2 Input Voltage Regulation

In addition to input current regulation, the device also offers input voltage regulation to limit the input power. This is especially useful when dealing with input sources such as solar panels, where the operating voltage must be controlled to extract the maximum power. Alternatively, if the input source current limitation is not known, input voltage regulation can be used to limit the power draw from the input source. By using input voltage regulation, the battery charger reduces the charging current when the input voltage falls below the input voltage limit set by the higher of VAC_DPM register bits, or ACUV pin.

There are two thresholds to limit the input voltage (the higher limit of these will apply)

1. VAC_DPM register bits (host software control)
2. ACUV pin falling threshold (hardware control)

To set the minimum input voltage using the VAC_DPM register bits, write the desired value directly to the VAC_DPM register bits. The default VAC_DPM is set to minimum code, allowing ACUV pin to limit the input voltage in hardware.

To set the minimum input voltage using the ACUV pin, refer to [Section 8.3.3.1](#).

8.3.5.1.2.1 Max Power Point Tracking (MPPT) for Solar PV Panel

When EN_MPPT bit is 1, the device provides a maximum power point tracking (MPPT) algorithm for solar PV panel input sources. The Input Power Maximizer algorithm finds and tracks the maximum power point by full panel sweep.

The full panel sweep is used to find the input operating voltage which delivers the maximum charge current to the battery. Before running a full panel sweep, the device momentarily enters HIZ mode to measure input source open-circuit voltage (V_{OC}). The device proceeds to reduce the input voltage regulation target, measuring the charge current output at each setting. The VAC_DPM register is used to program the minimum voltage to exit the full panel sweep. After the sweep is complete, the device updates the VAC_MPP register to the input voltage regulation value producing the maximum charge current. The device then waits for a period of FULL_SWEEP_TMR[1:0] before performing a new full panel sweep. A full panel sweep can be forced at any time by setting the FORCE_SWEEP bit to 1. Note that EN_MPPT = 1 is required for FORCE_SWEEP to work. The FORCE_SWEEP bit is automatically cleared to 0 after the full panel sweep is completed. Note that the device uses the internal ADC to determine the charge current at each step of the full panel sweep, therefore writes to the IBAT_ADC_DIS bit are ignored while MPPT is enabled (EN_MPPT = 1).

Note that when the system is directly connected to the input supply, the device cannot limit the system load. Therefore, the MPPT algorithm may not find and track the true MPP under all conditions. To enable MPPT operation, it is recommended to connect the system load directly in parallel to the battery pack.

8.3.6 Reverse Mode Power Direction

The device supports buck-boost reverse power direction with CC/CV profile to deliver power from the battery to the input when the adapter is not present. The reverse mode output voltage regulation is set in VAC_REV register bits. The reverse mode also offers output current regulation via the R_{AC_SNS} resistor. This parameter is controlled by the IAC_REV register bits. The reverse mode operation can be enabled if the following conditions are valid:

1. SRN above 3 V.
2. DRV_SUP voltage within valid operating window ($V_{DRV_UVP} < V_{DRV} < V_{DRV_OVP}$).
3. VAC outside the ACOV / ACUV operating window, or $V_{VAC} < V_{VAC_OK}$, or $V_{VAC} > V_{VAC_INT_OV}$
4. Reverse mode operation is enabled (EN_REV = 1)
5. Voltage at TS (thermistor) pin is within range configured by Reverse Temperature Monitor as configured by BHOT and BCOLD register bits

While the reverse mode is active, the device sets the REVERSE_STAT bit to 1. Host can disable the reverse operation at any time by setting EN_REV bit to 0.

The charger also monitors and regulates the battery discharging current in reverse mode. When the battery discharge current rises above the IBAT_REV register setting, the charger reduces the reverse mode power flow to limit the discharge current.

8.3.7 Integrated 16-Bit ADC for Monitoring

The device includes a 16-bit ADC to monitor critical system information based on the device's modes of operation. The ADC is allowed to operate if either the $V_{VAC} > V_{VAC_OK}$ or $V_{BAT} > V_{REGN_OK}$ is valid. The ADC_EN bit provides the ability to enable and disable the ADC to conserve power. The ADC_RATE bit allows continuous conversion or one-shot behavior. After a one-shot conversion finishes, the ADC_EN bit is cleared, and must be re-asserted to start a new conversion.

The ADC_SAMPLE bits control the resolution and sample speed of the ADC. By default, ADC channels will be converted in one-shot or continuous conversion mode unless disabled in the ADC Function Disable register. If an ADC parameter is disabled by setting the corresponding bit, then the read-back value in the corresponding register will be from the last valid ADC conversion or the default POR value (all zeros if no conversions have taken place). If an ADC parameter is disabled in the middle of an ADC measurement cycle, the device will finish the conversion of that parameter, but will not convert the parameter starting the next conversion cycle. If all channels are disabled in one-shot conversion mode, the ADC_EN bit is cleared.

The ADC_DONE_STAT and ADC_DONE_FLAG bits signal when a conversion is complete in one-shot mode only. This event produces an INT pulse, which can be masked with ADC_DONE_MASK. During continuous conversion mode, the ADC_DONE_STAT bit has no meaning and will be '0'. The ADC_DONE_FLAG bit will remain unchanged in continuous conversion mode.

ADC conversion operates independently of the faults present in the device. ADC conversion will continue even after a fault has occurred (such as one that causes the power stage to be disabled), and the host must set ADC_EN = '0' to disable the ADC. ADC readings are only valid for DC states and not for transients. When host writes ADC_EN = 0, the ADC stops immediately, and ADC measurement values correspond to last valid ADC reading.

If the host wants to exit ADC more gracefully, it is possible to do either of the following:

1. Write ADC_RATE to one-shot, and the ADC will stop at the end of a complete cycle of conversions, or
2. Disable all ADC conversion channels, and the ADC will stop at the end of the current measurement.

When system load is powered from the battery (input source is removed, or device in HIZ mode), enabling the ADC automatically powers up REGN and increases the quiescent current. To keep the battery leakage low, it is recommended to duty cycle or completely disable the ADC.

8.3.8 Status Outputs (\overline{PG} , STAT1, STAT2, and \overline{INT})

8.3.8.1 Power Good Indicator (\overline{PG})

The PG_STAT bit goes HIGH and the \overline{PG} pin pulls LOW to indicate a good input source when a valid VAC voltage is detected. The \overline{PG} pin can drive an LED. All conditions must be met to indicate power good:

1. $V_{VAC_OK} < V_{VAC} < V_{VAC_INT_OV}$
2. $V_{ACUV} > V_{REF_ACUV}$
3. $V_{ACOV} < V_{REF_ACOV}$
4. Device not in HIZ mode

The \overline{PG} pin can be disabled via the DIS_PG_PIN bit. When disabled, this pin can be controlled to pull LOW using the FORCE_STAT3_ON bit.

8.3.8.2 Charging Status Indicator (STAT1, STAT2 Pins)

The device indicates charging state on the open drain STAT1 and STAT2 pins. The STAT1, STAT2 pins can drive LEDs.

Table 8-6. STAT1, STAT2 Pin State

CHARGING STATE	STAT1	STAT2
Charge in progress (including recharge)	ON	OFF
Charge done	OFF	ON
Charging fault detected (TS out of range, safety timer fault, etc.)	ON	ON
Charge disabled (EN_CHG = 0, or CE pin high)	OFF	OFF

The STAT1, STAT2 pin function can be disabled via the DIS_STAT_PINS bit. When disabled, these pins can be controlled to independently pull LOW using the FORCE_STAT1_ON and FORCE_STAT2_ON bits. The STAT pins are not affected by the Reverse mode and remain OFF during this mode.

8.3.8.3 Interrupt to Host (\overline{INT})

In some applications, the host does not always monitor the charger operation. The \overline{INT} pin notifies the system host on the device operation. By default, the following events will generate an active-low, 256- μ s INT pulse.

1. Valid input source conditions detected (see conditions for \overline{PG} pin)
2. Valid input source conditions removed (see conditions for \overline{PG} pin)
3. Entering IAC_DPM regulation through register or ILIM_HIZ pin
4. Entering VAC_DPM regulation through register or ACUV pin
5. I²C Watchdog timer expired
6. Charger status changes state (CHARGE_STAT value change), including Charge Complete
7. TS_STAT changes state (TS_STAT value change)
8. Junction temperature shutdown (TSHUT)
9. Battery overvoltage detected (BATOVP)
10. Charge safety timer expired (including pre-charge or CV timer expiration)
11. A rising edge on any of the *_STAT bits

Each one of these INT sources can be masked off to prevent INT pulses from being sent out when they occur. Three bits exist for each one of these events:

- The STAT bit holds the *current status* of each INT source
- The FLAG bit holds information on which source produced an INT, regardless of the current status
- The MASK bit is used to prevent the device from sending out INT for each particular event

When one of the above conditions occurs (a rising edge on any of the *_STAT bits), the device sends out an INT pulse and keeps track of which source generated the INT via the FLAG registers. The FLAG register bits are automatically reset to zero after the host reads them, and a new edge on STAT bit is required to re-assert the FLAG.

Figure 8-6. INT Generation Behavior Example

8.3.9 Protections

The device closely monitors the input and battery voltage, as well as switching FET currents for safe switch-mode operation.

8.3.9.1 Voltage and Current Monitoring

8.3.9.1.1 VAC Over-voltage Protection (VAC_OVP)

In order to protect downstream devices on the system rail, the input over-voltage threshold can be programmed with the ACOV pin as $V_{VACOV} = V_{REF_ACOV}$ (refer to [Section 8.3.3.1](#)). The device also features an internal over-voltage protection preset at $V_{VAC_INT_OV}$. When the input voltage rises above the lower of these two thresholds, the device disables the charger. During input over-voltage, an INT pulse is asserted to signal the host, and the VAC_OV_STAT, and _FLAG bits are set. Additionally, the PG_STAT bit is cleared and the PG pin pulls HIGH. The device automatically resumes charging operation when the over-voltage condition goes away.

8.3.9.1.2 VAC Under-voltage Protection (VAC_UVP)

In order to maintain a minimum operating voltage on the system rail, the input under-voltage threshold can be programmed with the ACUV pin as $V_{VACUV} = V_{REF_ACUV}$ (refer to [Section 8.3.3.1](#)). The device also features an internal under-voltage protection preset at V_{VAC_OK} . When the input voltage falls below the higher of these two thresholds, the device disables the charger. During input under-voltage, an INT pulse is asserted to signal the host, and the VAC_UV_STAT, and _FLAG bits are set. Additionally, the PG_STAT bit is cleared and the PG pin pulls HIGH. The device automatically resumes charging operation when the under-voltage condition goes away.

8.3.9.1.3 Battery Over-voltage Protection (BAT_OVP)

The device protects against battery over-charge using the BAT_OVP comparator. When the FB voltage exceeds V_{BAT_OV} , the converters stops switching immediately and prevents the high-side FETs to turn on until the battery feedback voltage falls below V_{BAT_OVZ} . This allows one-cycle response to an overvoltage condition, such as occurs when the load is removed or the battery is disconnected. During the BAT_OVP event, the I_{BAT_LOAD} turns on and sinks current from SRN to GND, allowing for the discharge of stored energy in the output capacitors. BAT_OVP also suspends the safety timer, top-off timer, and CV timer.

8.3.9.1.4 Battery Over-current Protection (BAT_OCP)

The device protects the battery against over-current condition using the BAT_OCP comparator. The device monitors the charge current and prevents the current from exceeding V_{ICHG_OC} over R_{BAT_SNS} . If V_{ICHG_OC} threshold is reached, the device stops charging and attempts to restart after one second.

8.3.9.1.5 Reverse Mode Over-voltage Protection (REV_OVP)

While operating the converter in reverse mode, the device monitors the reverse voltage, V_{VAC} . When V_{VAC} rises above regulation target and exceeds V_{REV_OVP} , the device stops switching, and waits for the voltage to fall below the threshold to resume switching. An INT pulse is asserted to the host.

8.3.9.1.6 Reverse Mode Under-voltage Protection (REV_UVP)

While operating the converter in reverse mode, the device monitors the reverse voltage, V_{VAC} . When V_{VAC} falls below the undervoltage threshold (programmable via SYSREV_UV register bit), the device stops switching, clears the EN_REV bit, and exits Reverse mode. During the over-voltage event duration, the REVERSE_STAT bit is cleared and the REVERSE_FLAG bit is set to indicate a fault in reverse mode. An INT pulse is also asserted to the host.

8.3.9.1.7 DRV_SUP Under-voltage and Over-voltage Protection (DRV_OKZ)

The DRV_SUP pin must maintain a valid voltage between DRV_UVP and DRV_OVP for proper operation of the switching power converter stage. This is true both in charging mode and in reverse mode.

When DRV_SUP pin voltage falls below DRV_UVP threshold, the switching converter stops operation, an INT pulse is asserted to signal the host, the DRV_OKZ_STAT, and DRV_OKZ_FLAG bits are set to signal the fault. Additionally, the STAT1 and STAT2 pins will change to reflect the charger function is disabled.

When DRV_SUP pin voltage rises above DRV_OVP threshold, the switching converter stops operation, an INT pulse is asserted to signal the host, the DRV_OKZ_STAT, and DRV_OKZ_FLAG bit are set to signal the fault. Additionally the STAT1 and STAT2 pins will change to reflect the charger function is disabled.

When the DRV pin returns to normal operating range, the device automatically resumes switching in either charging or reverse mode as configured before the fault.

8.3.9.1.8 REGN Under-voltage Protection (REGN_OKZ)

The REGN pin is driven by an internal regulator, and must maintain a voltage above REGN_OKZ for proper device operation. This is true both in charging mode and in reverse mode, and for the ADC to function in battery only mode.

If the internal regulator is overloaded externally, the pin voltage may drop. When REGN falls below REGN_OKZ threshold, the switching converter stops operation. Additionally, the STAT1 and STAT2 pins will change to reflect the charger function is disabled. When the fault is removed, the REGN voltage recovers automatically and switching resumes in either charging or reverse mode as configured before the fault.

8.3.9.2 Thermal Shutdown (TSHUT)

The device has thermal shutdown to turn off the converter when IC surface temperature exceeds TSHUT. The fault register bits TSHUT_STAT and TSHUT_FLAG are set and an INT pulse is asserted to the host. The converter turns back on when IC temperature is below TSHUT_HYS. Note that TSHUT protection is active both in charging and reverse mode of operation.

8.3.10 Serial Interface

The device uses I²C compatible interface for flexible charging parameter programming and instantaneous device status reporting. I²C is a bi-directional 2-wire serial interface. Only two open-drain bus lines are required: a serial data line (SDA), and a serial clock line (SCL). Devices can be considered as controllers or targets when performing data transfers. A controller is a device which initiates a data transfer on the bus and generates the clock signals to permit that transfer. At that time, any device addressed is considered a target.

The device operates as a target device with address 0x6A, receiving control inputs from the controller device like a micro-controller or digital signal processor through the registers defined in the Register Map. Registers read

outside those defined in the map, return 0xFF. The I²C interface supports standard mode (up to 100 kbit/s), fast mode (up to 400 kbit/s), and fast mode plus (up to 1 Mbit/s). When the bus is free, both lines are HIGH. The SDA and SCL pins are open drain and must be connected to the positive supply voltage via a current source or pull-up resistor.

System Note: All 16-bit registers are defined as Little Endian, with the most-significant byte allocated to the higher address. 16-bit register writes must be done sequentially and are recommended to be programmed using multi-write approach described in the [Section 8.3.10.7](#).

8.3.10.1 Data Validity

The data on the SDA line must be stable during the HIGH period of the clock. The HIGH or LOW state of the data line can only change when the clock signal on SCL line is LOW. One clock pulse is generated for each data bit transferred.

Figure 8-7. Bit Transfers on the I²C Bus

8.3.10.2 START and STOP Conditions

All transactions begin with a START (S) and are terminated with a STOP (P). A HIGH to LOW transition on the SDA line while SCL is HIGH defines a START condition. A LOW to HIGH transition on the SDA line when the SCL is HIGH defines a STOP condition.

START and STOP conditions are always generated by the controller. The bus is considered busy after the START condition, and free after the STOP condition. When timeout condition is met, for example START condition is active for more than 2 seconds and there is no STOP condition triggered, the charger I²C communication will automatically reset and communication lines are free for another transmission.

Figure 8-8. START and STOP Conditions on the I²C Bus

8.3.10.3 Byte Format

Every byte on the SDA line must be 8 bits long. The number of bytes to be transmitted per transfer is unrestricted. Each byte has to be followed by an ACKNOWLEDGE (ACK) bit. Data is transferred with the Most Significant Bit (MSB) first. If a target cannot receive or transmit another complete byte of data until it has performed some other function, it can hold the SCL line low to force the controller into a wait state (clock

stretching). Data transfer then continues when the target is ready for another byte of data and releases the SCL line.

Figure 8-9. Data Transfer on the I²C Bus

8.3.10.4 Acknowledge (ACK) and Not Acknowledge (NACK)

The ACK signaling takes place after byte. The ACK bit allows the target to signal the controller that the byte was successfully received and another byte may be sent. All clock pulses, including the acknowledge 9th clock pulse, are generated by the controller.

The controller releases the SDA line during the acknowledge clock pulse so the target can pull the SDA line LOW and it remains stable LOW during the HIGH period of this 9th clock pulse.

A NACK is signaled when the SDA line remains HIGH during the 9th clock pulse. The controller can then generate either a STOP to abort the transfer or a repeated START to start a new transfer.

8.3.10.5 Target Address and Data Direction Bit

After the START signal, a target address is sent. This address is 7 bits long, followed by the 8 bit as a data direction bit (bit R/ W̄). A zero indicates a transmission (WRITE) and a one indicates a request for data (READ). The device 7-bit address is defined as 1101 011' (0x6A) by default.

Figure 8-10. Complete Data Transfer on the I²C Bus

8.3.10.6 Single Write and Read

Figure 8-11. Single Write

Figure 8-12. Single Read

If the register address is not defined, the charger IC sends back NACK and returns to the idle state.

8.3.10.7 Multi-Write and Multi-Read

The charger device supports multi-read and multi-write of all registers.

Figure 8-13. Multi-Write

Figure 8-14. Multi-Read

8.4 Device Functional Modes

8.4.1 Host Mode and Default Mode

The device is a host controlled charger, but it can operate in default mode without host management. In default mode, the device can be used as an autonomous charger with no host or while host is in sleep mode. When the charger is in default mode, WD_STAT bit becomes HIGH, WD_FLAG is set to 1, and a $\overline{\text{INT}}$ is asserted low to alert the host (unless masked by WD_MASK). The WD_FLAG bit would read as a '1' upon the first read and then '0' upon subsequent reads. When the charger is in host mode, WD_STAT bit is LOW.

After power-on-reset, the device starts in default mode with watchdog timer expired. All the registers are in the default settings.

In default mode, the device keeps charging the battery with default 2-hour pre-charging safety timer and the 12-hour fast charging safety timer. At the end of the 2-hour or 12-hour timer expiration, the charging is stopped if termination has not been detected.

A write to any I²C register transitions the charger from default mode to host mode, and initiates the watchdog timer. All the device parameters can be programmed by the host. To keep the device in host mode, the host has to reset the watchdog timer by writing 1 to WD_RST bit before the watchdog timer expires (WD_STAT bit is set), or disable watchdog timer by setting WATCHDOG bits = 00.

When the watchdog timer is expired, the device returns to default mode and select registers are reset to default values as detailed in the Register Map section. The Watchdog timer will be reset on any write if the watchdog timer has expired. When watchdog timer expires, WD_STAT and WD_FLAG is set to 1, and /INT is asserted low to alert the host (unless masked by WD_MASK).

Figure 8-15. Watchdog Timer Flow Chart

8.4.2 Register Bit Reset

Beside the register reset by the watchdog timer in the default mode, the register and the timer could be reset to the default value by writing the REG_RST bit to 1. The register bits which can be reset by the REG_RST bit, are noted in the Register Map section. After the register reset, the REG_RST bit will go back from 1 to 0 automatically.

8.5 BQ25756E Registers

Table 8-7 lists the memory-mapped registers for the BQ25756E registers. All register offset addresses not listed in Table 8-7 should be considered as reserved locations and the register contents should not be modified.

9 Application and Implementation

Note

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes, as well as validating and testing their design implementation to confirm system functionality.

9.1 Application Information

9.2 Typical Applications

9.2.1 Typical Application

The device can be configured as a solar charger using the [MPPT Control register \(REG1A\)](#). When the input source falls outside the VAC operating window programmed through ACUV and ACOV, the device automatically stops switching. [Figure 9-1](#) shows a typical schematic when using the device as a solar charging from either single 18-V panel or two panels in series up-to 36 Vin. The charging parameters and MPPT search window are programmed via the I²C registers.

Figure 9-1. BQ25756E: Solar Charging with Autonomous MPPT Algorithm to Charge 4s Battery with Maximum 15-A Charge Current

Table 9-1. Recommended Part Numbers:

COMPONENT	VALUE	RECOMMENDED PART NUMBER
Q1, Q2, Q3, Q4	60 V, 3.1 mΩ	AONS66614

Table 9-1. Recommended Part Numbers: (continued)

COMPONENT	VALUE	RECOMMENDED PART NUMBER
L1	10 μ H, 12 m Ω	IHLP6767GZ-01

9.2.1.1 Design Requirements

For this design example, use the parameters shown in the table below.

Table 9-2. Design Parameters

PARAMETER	VALUE
Input voltage operating range (V_{AC})	12 V to 36 V
Input current limit (I_{AC})	Optimal current determined by MPPT
Output current limit (I_{OUT})	15 A
Battery charge voltage (V_{BAT_REG})	17.4 V
Switching frequency	250 kHz

9.2.1.2 Detailed Design Procedure

9.2.1.2.1 ACUV / ACOV Input Voltage Operating Window Programming

The input voltage operating window is programmed by an ACUV / ACOV window with a resistor divider from VAC to GND. The top resistor, RAC1 is typically selected as 1,000 k Ω to minimize the input voltage leakage current. Assuming the desired trip-points for under-voltage and over-voltage protection are labeled V_{VACUVP} and V_{VACOVP} , the resistor divider required can be calculated as follows. The internal reference for the over-voltage threshold (VREF_ACOV) is 1.2 V. The internal reference for the under-voltage threshold (VREF_ACUV) is 1.1 V.

Figure 9-2. ACUV and ACOV Resistor Divider

$$V_{VACOVP} = \frac{1.2V(1,000k\Omega + R_{AC2} + R_{AC3})}{R_{AC3}} \quad (8)$$

$$V_{VACUVP} = \frac{1.1V(1,000k\Omega + R_{AC2} + R_{AC3})}{R_{AC2} + R_{AC3}} \quad (9)$$

For the default device operating window of 4.2 V to 36 V, the ACUV can be pulled up directly to VAC, while the ACOV can be pulled directly to GND.

9.2.1.2.2 Charge Voltage Selection

The battery regulation voltage is programmed using a resistor divider to the FB pin. The default internal voltage reference is 1.536 V, and can be changed via the VFB_REG register bits. The top of the resistor divider is selected to be 249 k Ω .

$$R_{TOP} = 249 \text{ k}\Omega$$

The bottom resistor can be calculated as:

$$R_{BOT} = R_{TOP} \times \frac{V_{FB}}{V_{BATREG} - V_{FB}} + R_{FBG} \quad (10)$$

where

- V_{FB} is the target feedback voltage programmed through I²C (default 1.536 V),
- V_{BATREG} is the desired battery regulation target (16.8 V in this example)
- R_{FBG} is the internal FBG pull-down resistor (33 Ω)

$$R_{FB_BOT} = 25.09 \text{ k}\Omega.$$

Choosing the nearest 0.1% resistor value, gives $R_{FB_BOT} = 24.88 \text{ k}\Omega$, for a nominal charge voltage of 16.89 V. Further fine-tuning of the regulation voltage can be achieved by changing the internal feedback reference. For example, to get the regulation voltage to exactly 16.8 V with the selected resistor divider, the internal voltage reference could be changed to 1.528 V via V_{FB_REG} .

It is recommended to use 0.1% accurate resistors to maximize the charge voltage accuracy.

9.2.1.2.3 Switching Frequency Selection

The switching frequency is set by a resistor connected from the FSW_SYNC pin to PGND. The RFSW resistor required to set the desired frequency is calculated using [Equation 3](#) or [Table 8-2](#). A 1% standard resistor of 133 kΩ is selected to set $f_{SW} = 250 \text{ kHz}$.

9.2.1.2.4 Inductor Selection

Higher switching frequency allows the use of smaller inductor and capacitor values. Inductor saturation current should be higher than the inductor current (I_L) plus half the ripple current (I_{RIPPLE}):

$$I_{SAT} \geq I_L + \frac{1}{2}I_{RIPPLE} \quad (11)$$

The inductor ripple current in buck operation depends on input voltage (V_{AC}), duty cycle ($D_{BUCK} = V_{BAT}/V_{AC}$), switching frequency (f_{SW}) and inductance (L):

$$I_{RIPPLE_BUCK} = \frac{V_{AC} \times D_{BUCK} \times (1 - D_{BUCK})}{f_{SW} \times L} \quad (12)$$

During boost operation, the duty cycle is: $D_{BOOST} = 1 - (V_{AC}/V_{BAT})$. The inductor ripple current is:

$$I_{RIPPLE_BOOST} = \frac{V_{AC} \times D_{BOOST}}{f_{SW} \times L} \quad (13)$$

The maximum inductor ripple current happens with $D = 0.5$ or close to 0.5. Ripple calculations should be analyzed for both forward and reverse operating modes if applicable.

Usually inductor ripple is designed in the range of (20 – 40%) maximum inductor current (in either forward or reverse mode) as a trade-off between inductor size and efficiency for a practical design.

9.2.1.2.5 Input (VAC) Capacitor

Input capacitor should have enough ripple current rating to absorb input switching ripple current. The worst case RMS ripple current is half of the output when duty cycle is 0.5 in forward buck mode, or reverse boost mode. If the converter does not operate at 50% duty cycle, then the worst case capacitor RMS current occurs where the duty cycle is closest to 50% and can be estimated by [Equation 14](#):

$$I_{CIN} = I_{CHG} \times \sqrt{D \times (1 - D)} \quad (14)$$

A combination of ceramic and bulk capacitors should be used to provide a short path for high di/dt current and to reduce the voltage ripple. Ceramic capacitors should be placed close to the switching half-bridge. Given total bulk input capacitance, it is recommended to distribute equally on either side of R_{AC_SNS} . The complete schematic is a good starting point for input capacitor for typical applications.

9.2.1.2.6 Output (VBAT) Capacitor

In forward boost mode or reverse buck mode, the output capacitor conducts high ripple current. The output capacitor RMS ripple current is given by where the minimum VAC corresponds to the maximum capacitor current.

$$I_{CBAT} = I_{BAT} \sqrt{\frac{V_{BAT}}{V_{AC}} - 1} \quad (15)$$

A 5-mΩ output capacitor ESR causes an output voltage ripple of 74 mV as given by:

$$\Delta V_{RIPPLE(ESR)} = I_{BAT} \times \frac{V_{BAT}}{V_{AC,min}} \times ESR \quad (16)$$

A 140-µF output capacitor causes a capacitive ripple voltage of 66 mV as given by:

$$\Delta V_{RIPPLE(CBAT)} = I_{BAT} \times \frac{\left(1 - \frac{V_{AC,min}}{V_{BAT}}\right)}{C_{BAT} \times f_{SW}} \quad (17)$$

A combination of ceramic and bulk capacitors should be used to provide low ESR and high ripple current capacity. Ceramic capacitors should be placed close to the switching half-bridge. Given total bulk output capacitance, it is recommended to distribute equally on either side of R_{BAT_SNS}. The complete schematic is a good starting point for C_{BAT} for typical applications.

9.2.1.2.7 Sense Resistor (R_{AC_SNS} and R_{BAT_SNS}) and Current Programming

The battery current sense resistor between SRP and SRN is fixed at 5 mΩ; using a different value is not recommended. The input current sense resistor between ACP and ACN is typically 2 mΩ, but can be increased to achieve better accuracy at lower sensed currents. In USB-PD EPR applications, a 5-mΩ sense resistor is recommended to achieve programmability in 50 mA/step. In addition, if input current limit function is not desired, ACP and ACN may be shorted together. For both of these sense resistors, a filter network is recommended as shown in the Typical Application.

For both the input current and the output current, the limits may be programmed using the I²C interface or an external programming resistor on ILIM_HIZ and ICHG pins, respectively.

PARAMETER	FORMULA	VALUE
Input Current Hardware Limit	Unused	Pull ILIM_HIZ pin to GND
Input Current Software Limit	Unused, set by MPPT	REG06 = 0x0640 (20 A with 5-mΩ R _{AC_SNS})
Output Current Hardware Limit	Unused	Pull ICHG pin to GND
Output Current Software Limit	ICHG = 15 A	REG02 = 0x04B0 (15 A)

The default input sense resistor (R_{AC_SNS}) is 2 mΩ, and the register allows for a range of up-to 50-A input current limit. If lower currents are desired, it is possible to use a higher resistor, such as 5 mΩ. In this case, the IAC_DPM register value should be multiplied by a factor of 2/5 to program the correct current. For example, if a 5-mΩ R_{AC_SNS} is used, and the register is programmed to a value of 0x60, the true maximum current across the R_{AC_SNS} will be: 12A * 2/5 = 4.8 A. Similarly, the K_{ILIM} parameter used to set the ILIM_HIZ pull-down resistor should be scaled by 2/5. For example, with a 5-mΩ R_{AC_SNS} resistor, a 6-A current limit would be achieved as: R_{ILIM} = K_{ILIM} * (2/5) / 6A = 3.3 kΩ.

9.2.1.2.8 Power MOSFETs Selection

Four external N-channel MOSFETs are used for a synchronous switching buck-boost battery charger. The gate drivers are integrated into the IC with 5 V of gate drive voltage. An external gate drive voltage can be provided directly into the DRV_SUP pin for increased efficiency.

Figure-of-merit (FOM) is usually used for selecting proper MOSFET based on a tradeoff between the conduction loss and switching loss. For the top side MOSFET, FOM is defined as the product of a MOSFET's on-resistance, $R_{DS(ON)}$, and the gate-to-drain charge, Q_{GD} . For the bottom side MOSFET, FOM is defined as the product of the MOSFET's on-resistance, $R_{DS(ON)}$, and the total gate charge, Q_G .

$$FOM_{top} = R_{DS(on)} \cdot Q_{GD}; FOM_{bottom} = R_{DS(on)} \cdot Q_G \quad (18)$$

The lower the FOM value, the lower the total power loss. Usually lower $R_{DS(ON)}$ has higher cost with the same package size.

The top-side MOSFET loss includes conduction loss and switching loss. Taking buck mode operation as an example the power loss is a function of duty cycle ($D=V_{OUT}/V_{IN}$), charging current (I_{CHG}), MOSFET's on-resistance ($R_{DS(ON)_top}$), input voltage (V_{IN}), switching frequency (f_S), turn-on time (t_{on}) and turn-off time (t_{off}):

$$P_{top} = P_{con_top} + P_{sw_top} \quad (19)$$

$$P_{con_top} = D \cdot I_{L_RMS}^2 \cdot R_{DS(on)_top}; \quad (20)$$

$$I_{L_RMS}^2 = I_{L_DC}^2 + I_{ripple}^2 / 12 \quad (21)$$

- I_{L_DC} is the average inductor DC current;
- I_{ripple} is the inductor current ripple peak-to-peak value;

$$P_{sw_top} = P_{IV_top} + P_{Qoss_top} + P_{Gate_top}; \quad (22)$$

The first item P_{con_top} represents the conduction loss which is straight forward. The second term P_{sw_top} represents the multiple switching loss items in top MOSFET including voltage and current overlap losses (P_{IV_top}), MOSFET parasitic output capacitance loss (P_{Qoss_top}) and gate drive loss (P_{Gate_top}). To calculate voltage and current overlap losses (P_{IV_top}):

$$P_{IV_top} = 0.5 \times V_{IN} \cdot I_{valley} \cdot t_{on} \cdot f_S + 0.5 \times V_{IN} \cdot I_{peak} \cdot t_{off} \cdot f_S \quad (23)$$

$$I_{valley} = I_{L_DC} - 0.5 \cdot I_{ripple} \text{ (inductor current valley value);} \quad (24)$$

$$I_{peak} = I_{L_DC} + 0.5 \cdot I_{ripple} \text{ (inductor current peak value);} \quad (25)$$

- t_{on} is the MOSFET turn-on time that V_{DS} falling time from V_{IN} to almost zero (MOSFET turn on conduction voltage);
- t_{off} is the MOSFET turn-off time that I_{DS} falling time from I_{peak} to zero;

The MOSFET turn-on and turn-off times are given by:

$$t_{on} = \frac{Q_{SW}}{I_{on}}, \quad t_{off} = \frac{Q_{SW}}{I_{off}} \quad (26)$$

where Q_{sw} is the switching charge, I_{on} is the turn-on gate driving current, and I_{off} is the turn-off gate driving current. If the switching charge is not given in MOSFET datasheet, it can be estimated by gate-to-drain charge (Q_{GD}) and gate-to-source charge (Q_{GS}):

$$Q_{sw} = Q_{GD} + Q_{GS} \quad (27)$$

Gate driving current can be estimated by REGN voltage (V_{REGN}), MOSFET plateau voltage (V_{plt}), total turn-on gate resistance (R_{on}), and turn-off gate resistance (R_{off}) of the gate driver:

$$I_{on} = \frac{V_{REGN} - V_{plt}}{R_{on}}, \quad I_{off} = \frac{V_{plt}}{R_{off}} \quad (28)$$

To calculate top MOSFET parasitic output capacitance loss (P_{Qoss_top}):

$$P_{Qoss_top} = 0.5 \cdot V_{IN} \cdot Q_{oss} \cdot f_S \quad (29)$$

- Q_{oss} is the MOSFET parasitic output charge which can be found in MOSFET datasheet. It is recommended to limit the total switch node capacitance C_{SW} (nF) < 160/VIN; for example, for a 36-V application, it is recommended to keep the total C_{SW} < 4.44 nF

To calculate top MOSFET gate drive loss (P_{Gate_top}):

$$P_{Gate_top} = V_{IN} \cdot Q_{Gate_top} \cdot f_S \quad (30)$$

- Q_{Gate_top} is the top MOSFET gate charge which can be found in MOSFET datasheet;
- Note here V_{IN} is used instead of real gate drive voltage because the gate drive is generated based on LDO from V_{IN} , the total gate drive related loss are all considered when V_{IN} is used for gate drive loss calculation.
- Alternatively, gate drive voltage can be supplied directly by external high efficiency supply into the DRV_SUP pin. In this case, the power loss to drive the gates becomes: $P_{Gate_top} = V_{DRV_SUP} \cdot Q_{Gate_top} \cdot f_S$

The bottom-side MOSFET loss also includes conduction loss and switching loss:

$$P_{bottom} = P_{con_bottom} + P_{sw_bottom} \quad (31)$$

$$P_{con_bottom} = (1 - D) \cdot I_{L,RMS}^2 \cdot R_{DS(on),bottom}; \quad (32)$$

$$P_{sw_bottom} = P_{RR_bottom} + P_{Dead_bottom} + P_{Gate_bottom}; \quad (33)$$

The first item P_{con_bottom} represents the conduction loss which is straight forward. The second term P_{sw_bottom} represents the multiple switching loss items in bottom MOSFET including reverse recovery losses (P_{RR_bottom}), Dead time body diode conduction loss (P_{Dead_bottom}) and gate drive loss (P_{Gate_bottom}). The detail calculation can be found below:

$$P_{RR_bottom} = V_{IN} \cdot Q_{rr} \cdot f_S \quad (34)$$

- Q_{rr} is the bottom MOSFET reverse recovery charge which can be found in MOSFET data sheet;

$$P_{Dead_bottom} = V_F \cdot I_{valley} \cdot f_S \cdot t_{dead_rise} + V_F \cdot I_{peak} \cdot f_S \cdot t_{dead_fall} \quad (35)$$

- V_F is the body diode forward conduction voltage drop;
- t_{dead_rise} is the SW rising edge deadtime between top and bottom MOSFETs which is around 45 ns;
- t_{dead_fall} is the SW falling edge deadtime between top and bottom MOSFETs which is around 45 ns;

P_{Gate_bottom} can follow the same method as top MOSFET gate drive loss calculation approach.

9.2.1.2.9 Converter Fast Transient Response

The device integrates all the loop compensation, thereby providing a high density solution with ease of use. For faster transient response in reverse operating mode, the EN_CONV_FAST_TRANSIENT bit can be set to 1. If device is not used in reverse boost mode operation, this section can be disregarded.

When the converter is operating in boost mode, the non-continuous inductor current flow to the load results in a right-half plane (RHP) zero. The RHP zero location is:

$$RHPz = \frac{V_{IN,boost}}{I_{IN,boost}} \frac{1}{2\pi L} \quad (36)$$

For good phase margin, the unity gain bandwidth (UGBW) of the converter should be about 1/3 of the RHPz. The boost output capacitor (C_{load}), and the converter transient parameters (R_1, gm_1) need to be scaled to move the location of the UGBW of the converter.

$$1 \approx \frac{Adiv \times gm_1(sR_1C_1 + 1)}{sC_1} \left[\frac{V_i}{I_o \times 50m} \right] \left[\frac{1}{1 + s \frac{C_{load}R_{load}}{2}} \right] \quad (37)$$

The device adjusts $Adiv$, gm_1 and R_1 based on the output voltage and the EN_CONV_FAST_TRANSIENT bit setting per the table below. During some boost case scenarios, the C_{load} needs to be adjusted to limit the converter bandwidth.

BOOST OUTPUT VOLTAGE	$Adiv$	C_1	EN_CONV_FAST_TRANSIENT = 0		EN_CONV_FAST_TRANSIENT = 1	
			gm_1	R_1	gm_1	R_1
≤8 V	1/5	75 pF	0.4 μ	600 kΩ	2 μ	1.3 MΩ
8 V to 16 V	1/10	75 pF	0.47 μ	1 MΩ	2 μ	1.8 MΩ
16 V to 32 V	1/20	75 pF	0.67 μ	2.8 MΩ	2 μ	2.8 MΩ
>32 V	1/40	75 pF	2 μ	2.8 MΩ	2 μ	2.8 MΩ

As an example, assume the device operates in reverse boost mode from a 5V supply to provide a 7V boost output voltage with load up-to 5A and 10μH inductor. The RHPz is approximately located at:

$$RHPz = \frac{V_{IN,boost}}{I_{IN,boost}} \frac{1}{2\pi L} = 11.4kHz \quad (38)$$

For best stability, the UGBW of the converter should be limited to 1/3 of the RHP zero, or 3.8kHz. If EN_CONV_FAST_TRANSIENT = 1, the equation becomes:

$$1 \approx \frac{0.2 \times 2\mu (j\omega \times 1.3M\Omega \times 75pF + 1)}{j\omega \times 75pF} \left[\frac{5V}{5A \times 50m} \right] \left[\frac{1}{1 + j\omega \frac{C_{load} \times 1.4}{2}} \right] \quad (39)$$

Solving the above for C_{load} gives ≥674 μF capacitor requirement.

Conversely, if EN_CONV_FAST_TRANSIENT = 0, the UGBW equation becomes:

$$1 \approx \frac{0.2 \times 0.4\mu (j\omega \times 0.6M\Omega \times 75pF + 1)}{j\omega \times 75pF} \left[\frac{5V}{5A \times 50m} \right] \left[\frac{1}{1 + j\omega \frac{C_{load} \times 1.4}{2}} \right] \quad (40)$$

Solving the above for C_{load} gives ≥51 μF capacitor requirement. However, the minimum recommended capacitor for converter stability is 80 μF, so this minimum value should be used.

9.2.1.3 Application Curves

$C_{VAC} = 160 \mu F$, $C_{OUT} = 160 \mu F$, $V_{VAC} = 20 V$, $V_{BAT} = 29.4 V$ (unless otherwise specified)

9.2.2 Typical Application (USB-PD EPR Configuration)

The device can be configured as a bidirectional buck-boost charger for USB-PD EPR charging applications. In this mode, the device can charge the battery from USB power and provide power back to the port when not charging. An optional gate drive voltage can be provided using the DRV_SUP pin to reduce switching losses. Figure 9-17 shows a typical schematic when using the device as a buck-boost charger for 10-cell Li-ion battery with USB-PD EPR input and bidirectional output for 240-W applications. The TPS26750 device communicates with the USB port, and controls the BQ25756E via I²C to charge with only the available power. In reverse mode, the TPS26750 negotiates with downstream device for the power profile, and controls the BQ25756E via I²C to provide the correct voltage and current to the USB port. The TPS2663x eFUSE can isolate the VBUS port from the BQ25756E input port when a fault is detected or the power source is removed.

Figure 9-17. BQ25756E: USB-PD EPR Input to Charge 10s Battery with up-to 240 W. Bidirectional Power Flow to Provide USB-PD EPR Power to the Input Port.

Table 9-3. Recommended Part Numbers:

COMPONENT	VALUE	RECOMMENDED PART NUMBER
Q1, Q2, Q3, Q4	80 V, 6.2 mΩ	SiR880BDP
L1	10 µH, 19 mΩ	CMLB135T-100MS

9.2.2.1 Design Requirements

For this design example, use the parameters shown in the table below.

Table 9-4. Design Parameters

PARAMETER	VALUE
Input voltage operating range (V_{AC})	5 V to 36V
Input current limit (I_{AC})	HW limit: 6.7 A SW limit: set by TPS26750 PD controller
Charge current limit (I_{CHG})	5 A
Battery charge voltage (V_{BAT_REG})	42 V
Switching frequency	450 kHz
Reverse Mode voltage regulation (VAC_REV)	Set by TPS26750: 5 V to 36 V
Reverse Mode current regulation (IAC_REV)	HW limit: 6.7 A SW limit: set by TPS26750 PD controller

10 Power Supply Recommendations

The power supply for the device is any DC voltage source within the specified input range. The supply should also be capable of supplying sufficient current based on the programmed input current limit. The input supply should be bypassed with a combination of electrolytic and ceramic capacitors to avoid ringing due to the parasitic impedance of the connecting cables.

When device is operating in the reverse direction, the supply at the OUTPUT should follow the same recommendations as the input supply mentioned above.

11 Layout

11.1 Layout Guidelines

Proper layout of the components to minimize high frequency current path loops is important to prevent electrical and magnetic field radiation and high frequency resonant problems. Here is a PCB layout priority list for proper layout.

Table 11-1. PCB Layout Guidelines

COMPONENTS	FUNCTION	IMPACT	GUIDELINES
Buck high side FET, Buck low side FET, input capacitors	Buck input loop	High frequency noise, ripple, efficiency	This path forms a high frequency switching loop due to the pulsating current at the input of the buck. Place components on the same side of the board. Minimize loop area to reduce parasitic inductance. Maximize trace width to reduce parasitic resistance. Place input ceramic capacitors close to the switching FETs.
Boost low side FET, boost high side FET, output capacitors	Boost output loop	High frequency noise, ripple, efficiency	This path forms a high frequency switching loop due to the pulsating current at the output of the boost. Place components on the same side of the board. Minimize loop area to reduce parasitic inductance. Maximize trace width to reduce parasitic resistance. Place output ceramic capacitors close to the switching FETs.
Sense resistors, switching FETs, inductor	Current path	Efficiency	The current path from input to output through the power stage and sense resistors has low impedance. Pay attention to via resistance if they are not on the same side. The number of vias can be estimated as 1- to 2-A per via for a 10-mil via with 1 oz. copper thickness.
Switching FETs, inductor	Power stage	Thermal, efficiency	The switching FETs and inductor are the components with highest power loss. Allow enough copper area for heat dissipation. Multiple thermal vias can be used to connect more copper layers together and dissipate more heat.
DRV_SUP, BTST1, BTST2 capacitors	Switching FET gate drive	High frequency noise, parasitic ringing, gate drive integrity	The DRV_SUP capacitor is used to supply the power to drive the low side FETs. The BTST capacitors are used to drive the high side FETs. It is recommended to place the capacitors as close as possible to the IC.
LODRV1, LODRV2	Low side gate drive	High frequency noise, parasitic ringing, gate drive integrity	LODRV1 and LODRV2 supplies the gate drive current to turn on the low side FETs. The return of LODRV1 and LODRV2 is PGND. As current take the path of least impedance, a ground plane close to the low side gate drive traces is recommended. Minimize gate drive length and aim for at least 20-mil gate drive trace width.
HIDRV1, HIDRV2, SW1 (pin trace), SW2 (pin trace)	High side gate drive	High frequency noise, parasitic ringing, gate drive integrity	HIDRV1 and HIDRV2 supplies the gate drive current to turn on the high side FETs. The return of HIDRV1 and HIDRV2 are SW1 and SW2, respectively. Route HIDRV1/SW1 and HIDRV2/SW2 pair next to each other to reduce gate drive parasitic inductance. Minimize gate drive length and aim for at least 20-mil gate drive trace width.

Table 11-1. PCB Layout Guidelines (continued)

COMPONENTS	FUNCTION	IMPACT	GUIDELINES
Current limit resistors, FSW_SYNC resistor	IC programmable settings	Regulation accuracy, switching integrity	Pin voltage determines the settings for input current limit, output current limit and switching frequency. Ground noise on these could lead to inaccuracy. Minimize ground return from these resistors to the IC ground pin.
Input (ACP, ACN) and output (SRP, SRN) current sense	Current regulation	Regulation accuracy	Use Kelvin-sensing technique for input and output current sense resistors. Connect the current sense traces to the center of the pads, and run current sense traces as differential pairs, away from switching nodes.
Input (ACUV), and output (FB, VO_SNS) voltage sensing	Voltage sense and regulation	Regulation accuracy	ACUV divider sets internal input voltage regulation in forward mode (V_{ACUV_DPM}). FB divider sets battery voltage regulation in forward mode (V_{FB_ACC}). Route the top of the divider point to the target regulation location. Avoid routing close to high power switching nodes.
Bypass capacitors	Noise filter	Noise immunity	Place lowest value capacitors closest to the IC.

11.2 Layout Example

Based on the above layout guidelines, the buck-boost PCB layout example top view is shown below including all the key power components.

**Figure 11-1. PCB Layout Reference Example Top View**

For both input and output current sensing resistors, differential sensing and routing method are suggested and highlighted in figure below. Use wide trace for gate drive traces, minimum 20-mil trace width. Connect all analog grounds to a dedicated low-impedance copper plane, which is tied to the power ground underneath the IC exposed pad.

Figure 11-2. PCB Layout Gate Drive and Current Sensing Signal Layer Routing

12 Device and Documentation Support

12.1 Device Support

12.1.1 Third-Party Products Disclaimer

TI'S PUBLICATION OF INFORMATION REGARDING THIRD-PARTY PRODUCTS OR SERVICES DOES NOT CONSTITUTE AN ENDORSEMENT REGARDING THE SUITABILITY OF SUCH PRODUCTS OR SERVICES OR A WARRANTY, REPRESENTATION OR ENDORSEMENT OF SUCH PRODUCTS OR SERVICES, EITHER ALONE OR IN COMBINATION WITH ANY TI PRODUCT OR SERVICE.

12.2 Receiving Notification of Documentation Updates

To receive notification of documentation updates, navigate to the device product folder on ti.com. Click on *Notifications* to register and receive a weekly digest of any product information that has changed. For change details, review the revision history included in any revised document.

12.3 Support Resources

[TI E2E™ support forums](#) are an engineer's go-to source for fast, verified answers and design help — straight from the experts. Search existing answers or ask your own question to get the quick design help you need.

Linked content is provided "AS IS" by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's [Terms of Use](#).

12.4 Trademarks

TI E2E™ is a trademark of Texas Instruments.

All trademarks are the property of their respective owners.

12.5 Electrostatic Discharge Caution

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

12.6 Glossary

[TI Glossary](#) This glossary lists and explains terms, acronyms, and definitions.

13 Revision History

NOTE: Page numbers for previous revisions may differ from page numbers in the current version.

DATE	REVISION	NOTES
November 2023	*	Initial Release

14 Mechanical, Packaging, and Orderable Information

The following pages include mechanical, packaging, and orderable information. This information is the most current data available for the designated devices. This data is subject to change without notice and revision of this document. For browser-based versions of this data sheet, refer to the left-hand navigation.

PACKAGING INFORMATION

Orderable part number	Status (1)	Material type (2)	Package Pins	Package qty Carrier	RoHS (3)	Lead finish/ Ball material (4)	MSL rating/ Peak reflow (5)	Op temp (°C)	Part marking (6)
BQ25756ERRVR	Active	Production	VQFN (RRV) 36	3000 LARGE T&R	Yes	NIPDAU	Level-1-260C-UNLIM	-40 to 125	B25756E
BQ25756ERRVR.A	Active	Production	VQFN (RRV) 36	3000 LARGE T&R	Yes	NIPDAU	Level-1-260C-UNLIM	-40 to 125	B25756E

⁽¹⁾ **Status:** For more details on status, see our [product life cycle](#).

⁽²⁾ **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

⁽³⁾ **RoHS values:** Yes, No, RoHS Exempt. See the [TI RoHS Statement](#) for additional information and value definition.

⁽⁴⁾ **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

⁽⁵⁾ **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

⁽⁶⁾ **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.

Important Information and Disclaimer: The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.
