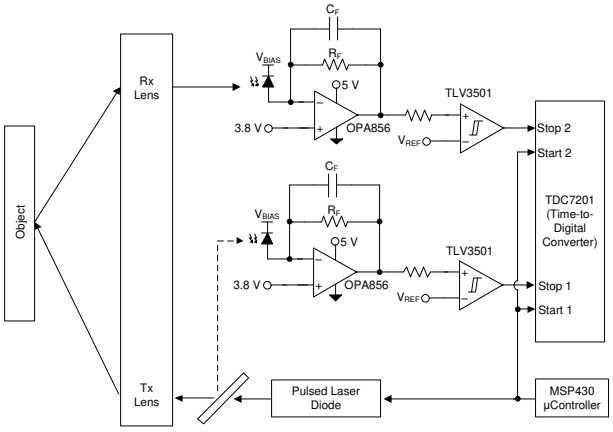
OPA856 1.1GHz 单位带宽增益积、0.9nV /√Hz，双极 输入放大器

1 特性

- 单位带宽增益积：1.1GHz
- 增益带宽积：1.1GHz
- 压摆率：350V/µs
- 低输入电压噪声：0.9nV/√Hz
- 低输入电容：
  - 共模：0.4pF
  - 差动：0.7pF
- 电源电压范围：3.3V 至 5.25V
- 封装：8 引脚 WSON
- 温度范围：–40°C 至 +125°C

2 应用

- 光时域反射计 (OTDR)
- 3D 扫描仪
- 激光测距
- 固态扫描激光雷达
- 光学 ToF 位置传感器
- 无人机视觉
- 工业机器人激光雷达
- 扫地机器人激光雷达
- 硅光电倍增器 (SiPM) 缓冲放大器
- 光电倍增管后置放大器



高速飞行时间接收器

3 说明

OPA856 是一款具有双极输入的宽带低噪声运算放大器，适用于宽带跨阻和电压放大器应用。将该器件配置为跨阻放大器 (TIA) 时，1.1GHz 增益带宽积 (GBWP) 能够在低电容光电二极管应用中实现高闭环带宽。

下图展示了将 OPA856 配置为 TIA 时，该放大器的带宽和噪声性能与光电二极管电容的函数关系。计算总噪声时的带宽范围为从直流到左轴上计算得出的频率 (*f*)。OPA856 封装具有一个反馈引脚 (FB)，可简化输入和输出之间的反馈网络连接。

OPA856 经过优化，可在光学飞行时间 (ToF) 系统中运行，在该系统中，OPA856 与时数转换器（如 TDC7201）配合使用。可在具有差分输出放大器（如 THS4541 或 LMH5401）的高分辨率激光雷达系统中使用 OPA856 来驱动高速模数转换器 (ADC)。

器件信息

器件型号(1)	封装	封装尺寸（标称值）
OPA856	WSON (8)	2.00 mm × 2.00 mm

(1) 如需了解所有可用封装，请参阅数据表末尾的封装选项附录。

Pin Functions

PIN		I/O	DESCRIPTION
NAME	NO.		
FB	1	I	Feedback connection to output of amplifier
IN–	3	I	Inverting input
IN+	4	I	Noninverting input
NC	2	—	Do not connect.
OUT	6	O	Amplifier output
$\overline{PD}$	8	I	Power down connection. $\overline{PD}$ = logic low = power off mode; $\overline{PD}$ = logic high = normal operation.
VS–	5	—	Negative voltage supply
VS+	7	—	Positive voltage supply
Thermal pad		—	Connect the thermal pad to VS–.

7 Specifications

7.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)(1)

		MIN	MAX	UNIT
V_S	Total supply voltage (V_{S+} – $V_{S–}$)		5.5	V
V_{IN+}, $V_{IN–}$	Input voltage	($V_{S–}$) – 0.5	(V_{S+}) + 0.5	V
V_{ID}	Differential input voltage		1	V
VOUT	Output voltage	($V_{S–}$) – 0.5	(V_{S+}) + 0.5	V
I_{IN}	Continuous input current		±10	mA
I_{OUT}	Continuous output current(2)		±100	mA
T_J	Junction temperature		150	°C
T_A	Operating free-air temperature	–40	125	°C
T_{stg}	Storage temperature	–65	150	°C

(1) Stresses beyond those listed under *Absolute Maximum Rating* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Condition*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
(2) Long-term continuous output current for electromigration limits.

7.2 ESD Ratings

			VALUE	UNIT
$V_{(ESD)}$	Electrostatic discharge	Human body model (HBM), per ANSI/ESDA/ JEDEC JS-001, all pins(1)	±1500	V
		Charged device model (CDM), per JEDEC specification JS-002, all pins(2)	±1500	

(1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
(2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

7.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

		MIN	NOM	MAX	UNIT
V_S	Total supply voltage (V_{S+} – $V_{S–}$)	3.3	5	5.25	V
T_A	Operating free-air temperature	–40		125	°C

7.4 Thermal Information

THERMAL METRIC(1)		OPA856 DSG (WSON) 8 PINS	UNIT
$R_{θJA}$	Junction-to-ambient thermal resistance	80.1	°C/W
$R_{θJC(top)}$	Junction-to-case (top) thermal resistance	100	°C/W
$R_{θJB}$	Junction-to-board thermal resistance	45	°C/W
$Ψ_{JT}$	Junction-to-top characterization parameter	6.8	°C/W
$Ψ_{JB}$	Junction-to-board characterization parameter	45.2	°C/W
$R_{θJC(bot)}$	Junction-to-case (bottom) thermal resistance	22.7	°C/W

(1) For more information about traditional and new thermal metrics, see the Semiconductor and IC Package Thermal Metrics application report.

7.5 Electrical Characteristics

at V_{S+} = 5 V, $V_{S–}$ = 0 V, G = 1 V/V, R_F = 0 Ω, input common-mode biased at midsupply, R_L = 200 Ω, output load is referenced to midsupply, and T_A = 25°C (unless otherwise noted)

8 Detailed Description

8.1 Overview

The ultra-wide, 1.1-GHz gain bandwidth product (GBWP) of the OPA856, combined with the broadband voltage noise of 0.9 nV/√Hz, produces a viable amplifier for wideband transimpedance applications, high-speed data acquisition systems, and applications with weak signal inputs that require low-noise and high-gain front ends. The OPA856 combines multiple features to optimize dynamic performance. In addition to the wide, small-signal bandwidth, the OPA856 has 110 MHz of large-signal bandwidth (V_{OUT} = 2 V_{PP}), and a slew rate of 350 V/µs.

The OPA856 is offered in a 2-mm × 2-mm, 8-pin WSON package that features a feedback (FB) pin for a simple feedback network connection between the amplifiers output and inverting input. Excess capacitance on an amplifiers input pin can reduce phase margin causing instability. This problem is exacerbated in the case of very wideband amplifiers like the OPA856. To reduce the effects of stray capacitance on the input node, the OPA856 pinout features an isolation pin (NC) between the feedback and inverting input pins that increases the physical spacing between them thereby reducing parasitic coupling at high frequencies. The OPA856 also features a very low capacitance input stage with only 1.1-pF of total input capacitance.

8.2 Functional Block Diagram

The OPA856 is a classic voltage feedback operational amplifier (op amp) with two high-impedance inputs and a low-impedance output. Standard application circuits are supported, like the two basic options shown in 图 8-1 and 图 8-2. The resistor on the noninverting pin is used for bias current cancellation to minimize the output offset voltage. In a noninverting configuration the additional resistors on the noninverting pin add noise to the system so if SNR is critical, the resistor can be eliminated. In an inverting configuration the noninverting node is typically connected to a DC voltage, so the high-frequency noise contribution from the bias cancellation resistor can be bypassed by adding a large 1-µF capacitor in parallel to the resistor to shunt the noise. The DC operating point for each configuration is level-shifted by the reference voltage (V_{REF}), which is typically set to midsupply in single-supply operation. V_{REF} is typically connected to ground in split-supply applications.

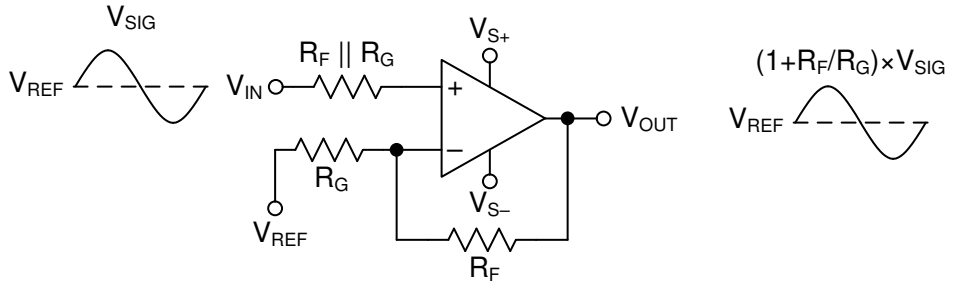

图 8-1. Noninverting Amplifier

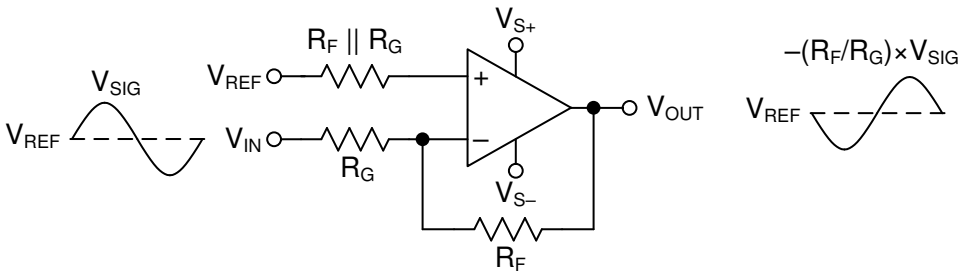

图 8-2. Inverting Amplifier

8.3 Feature Description

8.3.1 Input and ESD Protection

The OPA856 is fabricated on a low-voltage, high-speed, BiCMOS process. The internal, junction breakdown voltages are low for these small geometry devices, and as a result, all device pins are protected with internal ESD protection diodes to the power supplies as 图 8-3 shows. There are two antiparallel diodes between the inputs of the amplifier that clamp the inputs during an overrange or fault condition.

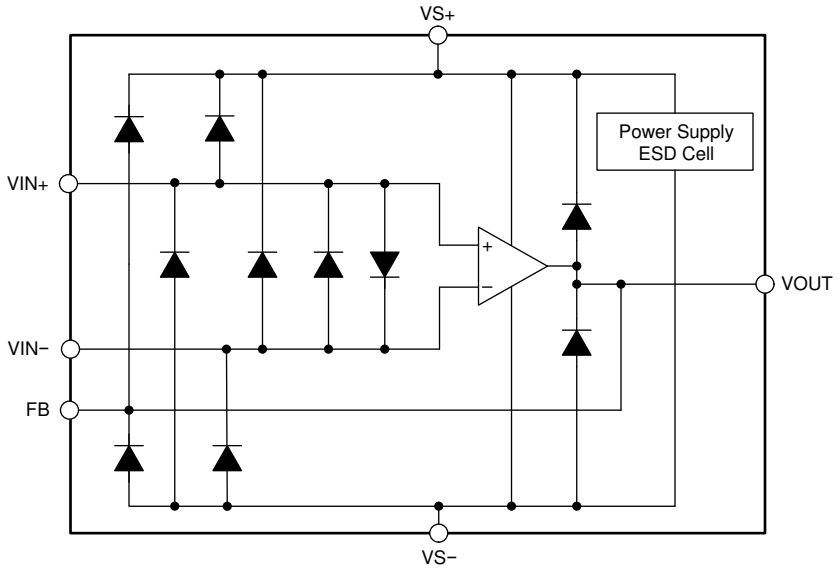

图 8-3. Internal ESD Structure

8.3.2 Feedback Pin

The OPA856 pin layout is optimized to minimize parasitic inductance and capacitance, which is a critical care about in high-speed analog design. The FB pin (pin 1) is internally connected to the output of the amplifier. The FB pin is separated from the inverting input of the amplifier (pin 3) by a no connect (NC) pin (pin 2). The NC pin must be left floating. There are two advantages to this pin layout:

1. A feedback resistor (R_F) can connect between the FB and IN– pin on the same side of the package (see 图 8-4) rather than going around the package.
2. The isolation created by the NC pin minimizes the capacitive coupling between the FB and IN– pins by increasing the physical separation between the pins.

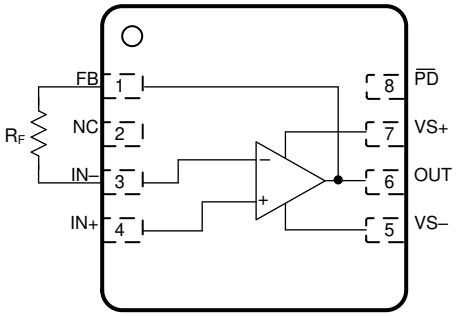

图 8-4. R_F Connection Between FB and IN– Pins

8.3.3 Wide Gain-Bandwidth Product

图 7-7 shows the open-loop magnitude and phase response of the OPA856. Calculate the gain bandwidth product of any op amp by determining the frequency at which the A_{OL} is 40 dB and multiplying that frequency by a factor of 100. The open-loop response shows the OPA856 to have approximately 57° of phase-margin when configured as a unity-gain buffer.

图 8-5 shows the open-loop magnitude (A_{OL}) of the OPA856 as a function of temperature. The results show minimal variation over the entire temperature range. Semiconductor process variation is the naturally occurring variation in the attributes of a transistor (Early-voltage, β, channel-length, and width) and other passive elements (resistors and capacitors) when fabricated into an integrated circuit. The process variation can occur across devices on a single wafer or across devices over multiple wafer lots over time. Typically the variation across a single wafer is tightly controlled. 图 8-6 shows the A_{OL} magnitude of the OPA856 as a function of process variation over time. The results show the A_{OL} curve for the nominal process corner and the variation one standard deviation from the nominal. The simulated results show less than 5° of phase-margin difference within a standard deviation of process variation when the amplifier is configured as a unity-gain bufffer.

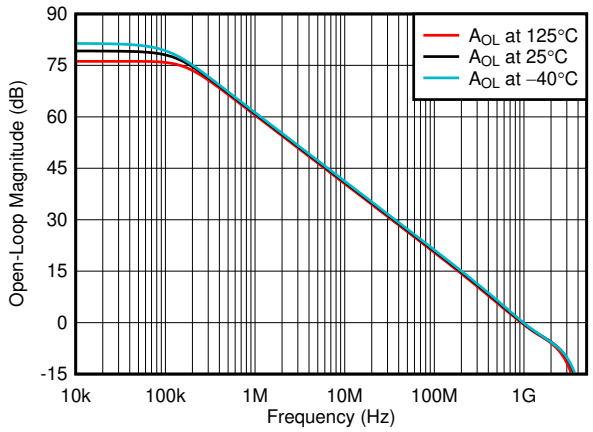

图 8-5. Open-Loop Gain vs Temperature

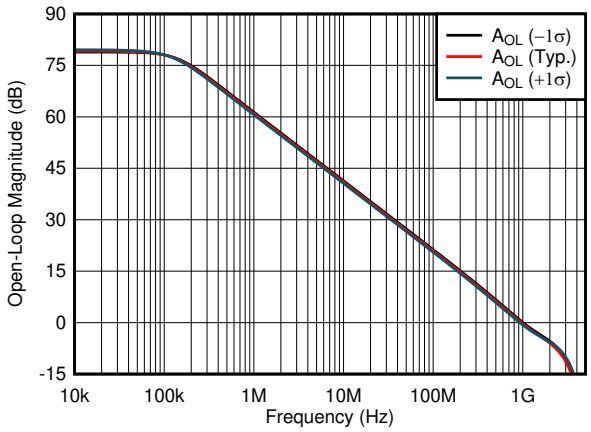

图 8-6. Open-Loop Gain vs Process Variation

8.3.4 Slew Rate and Output Stage

In addition to wide bandwidth, the OPA856 features a high slew rate of 2750 V/µs. The slew rate is a critical parameter in high-speed pulse applications with narrow sub-10-ns pulses, such as optical time-domain reflectometry (OTDR) and LIDAR. The high slew rate of the OPA856 implies that the device accurately reproduces a 2-V, sub-ns pulse edge, as seen in 图 7-18. The wide bandwidth and slew rate of the OPA856 make it an excellent amplifier for high-speed signal-chain front ends.

图 8-7 shows the open-loop output impedance of the OPA856 as a function of frequency. To achieve high slew rates and low output impedance across frequency, the output swing of the OPA856 is limited to approximately 3 V. The OPA856 is typically used in conjunction with high-speed pipeline ADCs and flash ADCs that have limited input ranges. Therefore, the OPA856 output swing range coupled with the class-leading voltage noise specification maximizes the overall dynamic range of the signal chain.

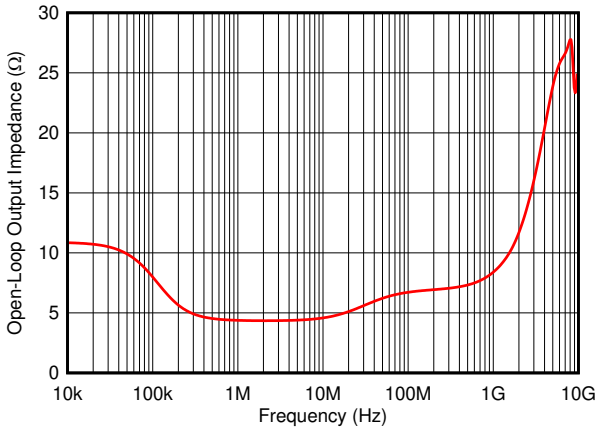

图 8-7. Open-Loop Output Impedance (Z_{OL}) vs Frequency

8.4 Device Functional Modes

8.4.1 Split-Supply and Single-Supply Operation

The OPA856 can be configured with single-sided supplies or split-supplies as shown in 图 10-1. Split-supply operation using balanced supplies with the input common-mode set to ground eases lab testing because most signal generators, network analyzers, spectrum analyzers, and other lab equipment typically reference inputs and outputs to ground. In split-supply operation, the thermal pad must be connected to the negative supply.

Newer systems use a single power supply to improve efficiency and reduce the cost of the extra power supply. The OPA856 can be used with a single positive supply (negative supply at ground) with no change in performance if the input common-mode and output swing are biased within the linear operation of the device. In single-supply operation, level shift the DC input and output reference voltages by half the difference between the power supply rails. This configuration maintains the input common-mode and output load reference at midsupply. To eliminate gain errors, the source driving the reference input common-mode voltage must have low output impedance across the frequency range of interest. In this case, the thermal pad must be connected to ground.

8.4.2 Power-Down Mode

The OPA856 features a power-down mode to reduce the quiescent current to conserve power. 图 7-19 and 图 7-20 show the transient response of the OPA856 as the $\overline{PD}$ pin toggles between the disabled and enabled states.

The $\overline{PD}$ disable and enable threshold voltages are with reference to the negative supply. If the amplifier is configured with the positive supply at 3.3 V and the negative supply at ground, then the disable and enable threshold voltages are 0.65 V and 1.8 V, respectively. If the amplifier is configured with ±1.65 V supplies, then the threshold voltages are at –1 V and 0.15 V. If the amplifier is configured with ±2.5 V supplies, then the threshold voltages are at –1.85 V and –0.7 V.

图 8-8 shows the switching behavior of a typical amplifier as the $\overline{PD}$ pin is swept down from the enabled state to the disabled state. Similarly, 图 8-9 shows the switching behavior of a typical amplifier as the $\overline{PD}$ pin is swept up from the disabled state to the enabled state. The small difference in the switching thresholds between the down sweep and the up sweep is caused by the hysteresis designed into the amplifier to increase immunity to noise on the $\overline{PD}$ pin.

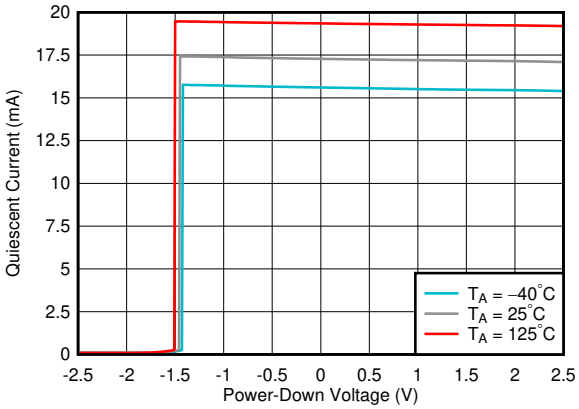

图 8-8. Switching Threshold ($\overline{PD}$ Pin Swept from High to Low)

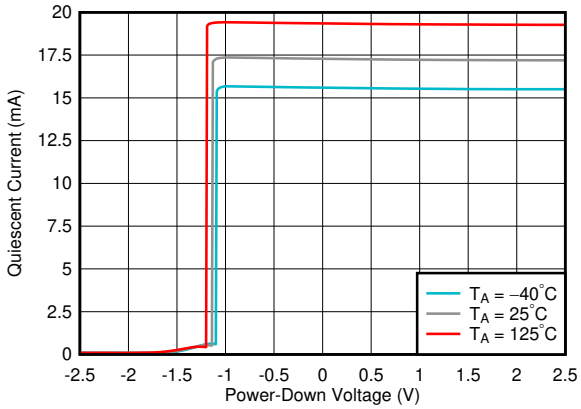

图 8-9. Switching Threshold ($\overline{PD}$ Pin Swept from Low to High)

Connecting the $\overline{PD}$ pin low disables the amplifier and places the output in a high-impedance state. When the amplifier is configured as a noninverting amplifier, the feedback (R_F) and gain (R_G) resistor network form a parallel load to the output of the amplifier. To protect the input stage of the amplifier, the OPA856 uses internal, back-to-back protection diodes between the inverting and noninverting input pins as 图 8-3 shows. In the power-down state, if the differential voltage between the input pins of the amplifier exceeds a diode voltage drop, an additional low-impedance path is created between the noninverting input pin and the output pin.

9 Application and Implementation

备注

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

9.1 Application Information

The OPA856 offers over 1 GHz of bandwidth, high slew-rate, low noise, excellent linearity, and is stable for unity gain applications. The low noise and unity gain stability make the OPA856 a great choice for use as a front-end buffer in high-speed data acquisition systems. Additionally the wide bandwidth allows the amplifier to perform excellently in transimpedance applications or in a high-gain active filter configuration.

9.2 Typical Application

The high GBWP of the OPA856 makes the device an excellent choice as a transimpedance amplifier while the unity gain stability allows for use of feedback clamping or other unity gain circuitry that would not work for a decompensated amplifier. 图 9-1 shows the OPA856 configured as a transimpedance amplifier with an option feedback clamping diode connection.

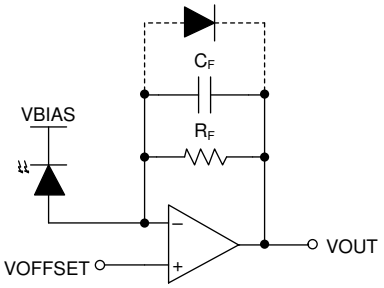

图 9-1. OPA856 Transimpedance Amplifier with Optional Diode Clamping

9.2.1 Design Requirements

The objective is to design a low noise, wideband optical front-end system using the OPA856

as a transimpedance amplifier. The design requirements are:

- Amplifier supply voltage: ± 2.5 V
- 1 kΩ transimpedance gain
- Transimpedance bandwidth > 100 MHz
- Total input capacitance 4 pF (1.1 pF from amplifier)

9.2.2 Detailed Design Procedure

The OPA856 meets the growing demand for wideband, low-noise photodiode amplifiers. The closed-loop bandwidth of a transimpedance amplifier is a function of the following:

1. The total input capacitance (C_{IN}). This total includes the photodiode capacitance, the input capacitance of the amplifier (common-mode and differential capacitance) and any stray capacitance from the PCB.
2. The op amp gain bandwidth product (GBWP).
3. The transimpedance gain (R_F).

图 9-1 shows the OPA856 configured as a TIA, with the photodiode reverse biased so that the diode cathode is tied to a positive bias voltage. In this configuration, the diode sources current into the op amp feedback loop so that the output swings in a negative direction relative to the input common-mode (VOFFSET) voltage. The feedback resistance (R_F) and the input capacitance (C_{IN}) form a zero in the noise gain that results in instability if left unchecked. To counteract the effect of the zero, a pole is inserted into the noise gain transfer function by adding the feedback capacitor (C_F).

The *Transimpedance Considerations for High-Speed Amplifiers Application Report* discusses theories and equations that show how to compensate a transimpedance amplifier for a particular transimpedance gain and input capacitance. The bandwidth and compensation equations from the application report are available in a Microsoft Excel ™ calculator. *What You Need To Know About Transimpedance Amplifiers – Part 1* provides a link to the calculator. Calculating the expected bandwidth with an approximate input capacitance of 4 pF and a feedback capacitor of 1 pF yields a bandwidth of approximately 200 MHz.

The amplifier was tested in a transimpedance configuration by using a photodiode with an optical fiber input connection. A tunable laser connected through an optical modulator was used to create the modulated optical excitation to the photodiode. 图 9-2 shows the test setup configuration for the frequency response measurement. The network analyzer's swept frequency output drives the optical modulators electrical input which in turn drives the photodiode. The OPA856 output drives the network analyzer's input.

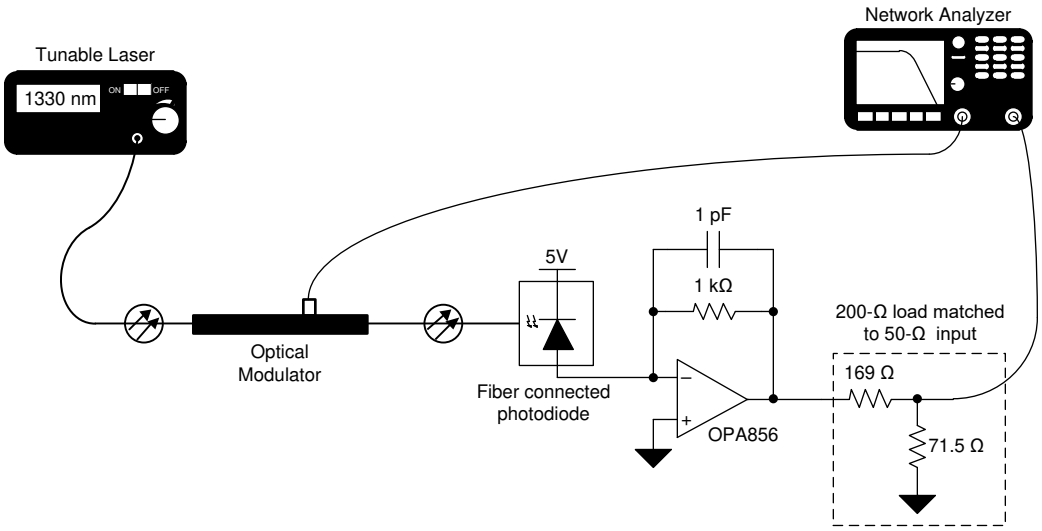

图 9-2. OPA856 Transimpedance Frequency Response Test Setup

图 9-4 shows the frequency response measurements for a small signal and large signal (~1 Vpp) output. The plot contains noticeable noise and variations because the test environment did not have complete capability to accurately manage the thermal drift, perform optical connection integrity analysis, and calibrate the optical path. A more stringently controlled optical environment could achieve more stable results, but was beyond the scope of these measurements. The results in 图 9-4 correlate well with predicted results of approximately 200 MHz of bandwidth. It is expected that the results would not perfectly match calculated values because it is challenging to perfectly account for all parasitic capacitances that affect the input and feedback capacitance in the transimpedance calculations.

Many transimpedance applications can have unpredicted, large input currents that can cause the amplifier's output to saturate. It is often important to understand how the amplifier will behave when its output is saturated at various levels of overdrive. A typical linear amplifier like the OPA856 can be expected to have an output saturation recovery time that increases as the amount of output overdrive increases. When using a pulse based input signal, the output saturation recovery time effectively extends the duration of the pulse. 图 9-3 shows the test setup configuration to measure a pulsed optical input to the OPA856. The optical modulator used in the test setup had limited output amplitude capability to create a saturated signal. In order to prevent the modulator from saturating, the OPA856 output was saturated by adjusting VOFFSET close to the the amplifier's output swing limit on the negative rail.

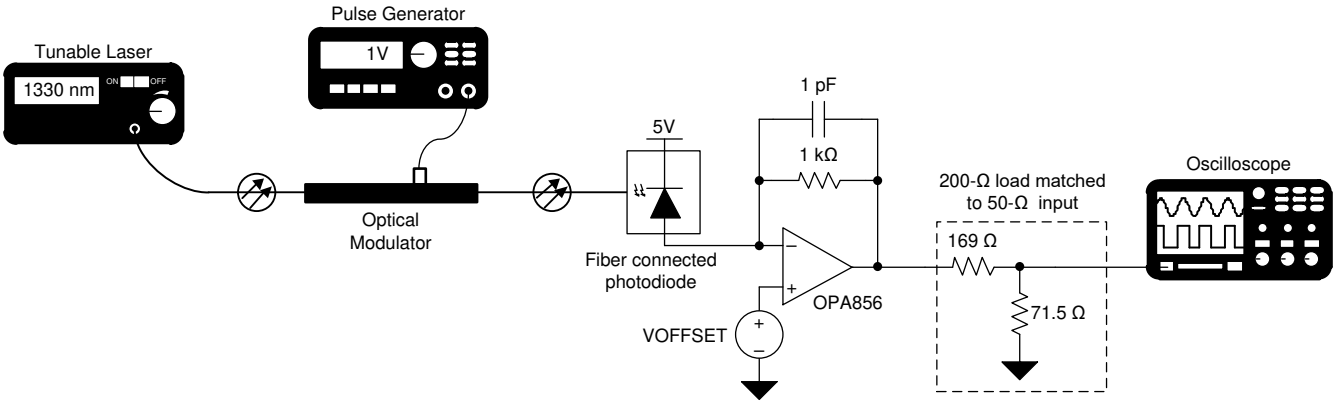

图 9-3. OPA856 Transimpedance Pulse Saturation Extention Test Setup

图 9-5 shows the resulting shifted output pulses labelled by the magnitude of voltage they are overdriving the amplifiers output saturation voltage level (V_{OV}). These values only serve as approximations of the overdrive level of the signal because of expected variances from the optical interface setup. 图 9-6 shows a magnified view of the rising edge of the measured pulse responses in order to better detail the pulse extension created by the signal overdrive. These plots have been scaled and normalized to be easier to read and compare. As expected, 图 9-6 shows that the pulse duration is extended as the overdrive level increases. The data only captured an overdrive voltage maximum of 640 mV, but it can be expected that larger voltages would extend the pulse further.

9.2.3 Application Curves

备注

图 9-6 output voltages are scaled for visual comparison purposes and are not the actual measured values. See 图 9-5 for actual measured values.

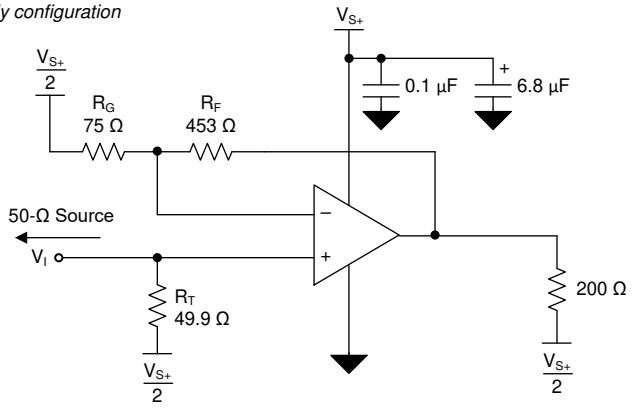
10 Power Supply Recommendations

The OPA856 operates on supplies from 3.3 V to 5.25 V. The OPA856 operates on single-sided supplies, split and balanced bipolar supplies, and unbalanced bipolar supplies. Because the OPA856 does not feature rail-to-rail inputs or outputs, the input common-mode and output swing ranges are limited at 3.3-V supplies.

a) Single supply configuration



b) Split supply configuration

11 Layout

11.1 Layout Guidelines

Achieving optimum performance with a high-frequency amplifier like the OPA856 requires careful attention to board layout parasitics and external component types. Recommendations that optimize performance include:

- **Minimize parasitic capacitance from the signal I/O pins to ac ground.** Parasitic capacitance on the output and inverting input pins can cause instability. To reduce unwanted capacitance, cut out the power and ground traces under the signal input and output pins. Otherwise, ground and power planes must be unbroken elsewhere on the board. When configuring the amplifier as a TIA, if the required feedback capacitor is less than 0.15 pF, consider using two series resistors, each of half the value of a single resistor in the feedback loop to minimize the parasitic capacitance from the resistor.
- **Minimize the distance (less than 0.25-in) from the power-supply pins to high-frequency bypass capacitors.** Use high-quality, 100-pF to 0.1-µF, C0G and NPO-type decoupling capacitors with voltage ratings at least three times greater than the amplifiers maximum power supplies. This configuration makes sure that there is a low-impedance path to the amplifiers power-supply pins across the amplifiers gain bandwidth specification. At the device pins, do not allow the ground and power plane layout to be in close proximity to the signal I/O pins. Avoid narrow power and ground traces to minimize inductance between the pins and the decoupling capacitors. The power-supply connections must always be decoupled with these capacitors. Larger (2.2-µF to 6.8-µF) decoupling capacitors that are effective at lower frequency must be used on the supply pins. Place these decoupling capacitors further from the device. Share the decoupling capacitors among several devices in the same area of the printed circuit board (PCB).
- **Careful selection and placement of external components preserves the high-frequency performance of the OPA856.** Use low-reactance resistors. Surface-mount resistors work best and allow a tighter overall layout. Never use wirewound resistors in a high-frequency application. Because the output pin and inverting input pin are the most sensitive to parasitic capacitance, always position the feedback and series output resistor, if any, as close to the output pin as possible. Place other network components (such as noninverting input termination resistors) close to the package. Even with a low parasitic capacitance shunting the external resistors, high resistor values create significant time constants that can degrade performance. When configuring the OPA856 as a voltage amplifier, keep resistor values as low as possible and consistent with load driving considerations. Decreasing the resistor values keeps the resistor noise terms low and minimizes the effect of the parasitic capacitance. However, lower resistor values increase the dynamic power consumption because R_F and R_G become part of the output load network of the amplifier.

12.6 Electrostatic Discharge Caution

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

12.7 术语表

TI 术语表　　本术语表列出并解释了术语、首字母缩略词和定义。

13 Mechanical, Packaging, and Orderable Information

The following pages include mechanical, packaging, and orderable information. This information is the most current data available for the designated devices. This data is subject to change without notice and revision of this document. For browser-based versions of this data sheet, refer to the left-hand navigation.

PACKAGING INFORMATION

Orderable part number	Status (1)	Material type (2)	Package | Pins	Package qty | Carrier	RoHS (3)	Lead finish/ Ball material (4)	MSL rating/ Peak reflow (5)	Op temp (°C)	Part marking (6)
OPA856IDSGR	Active	Production	WSON (DSG) | 8	3000 | LARGE T&R	Yes	NIPDAU	Level-1-260C-UNLIM	-40 to 125	856
OPA856IDSGR.B	Active	Production	WSON (DSG) | 8	3000 | LARGE T&R	Yes	NIPDAU	Level-1-260C-UNLIM	-40 to 125	856

(1) **Status:** For more details on status, see our product life cycle.

(2) **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

(3) **RoHS values:** Yes, No, RoHS Exempt. See the TI RoHS Statement for additional information and value definition.

(4) **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

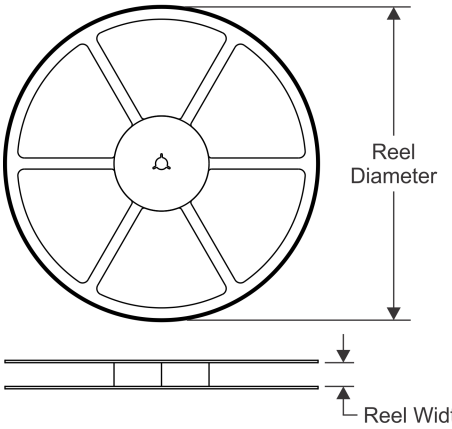
(5) **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

(6) **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

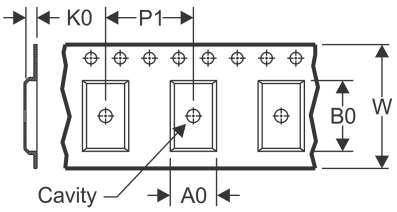
Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.

TAPE AND REEL INFORMATION

REEL DIMENSIONS

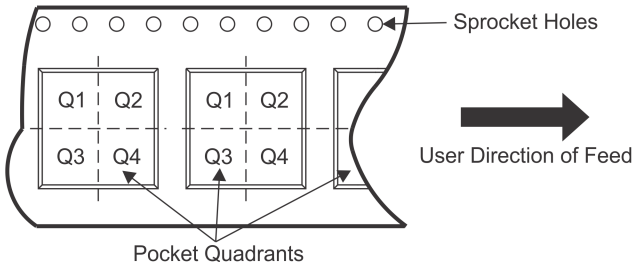


TAPE DIMENSIONS



A0	Dimension designed to accommodate the component width
B0	Dimension designed to accommodate the component length
K0	Dimension designed to accommodate the component thickness
W	Overall width of the carrier tape
P1	Pitch between successive cavity centers

QUADRANT ASSIGNMENTS FOR PIN 1 ORIENTATION IN TAPE



*All dimensions are nominal

Device	Package Type	Package Drawing	Pins	SPQ	Reel Diameter (mm)	Reel Width W1 (mm)	A0 (mm)	B0 (mm)	K0 (mm)	P1 (mm)	W (mm)	Pin1 Quadrant
OPA856IDSGR	WSON	DSG	8	3000	180.0	8.4	2.3	2.3	1.15	4.0	8.0	Q2

TAPE AND REEL BOX DIMENSIONS
