- (1) See core-specific tables for the internal memory map.
- (2) In Lockstep mode, the R5FSSx CORE1 memory region is not accessible.
- (3) The size of these memories changes based on Dual-Core vs Lockstep operation.  
For more information about Dual-Core and Lockstep modes, see the *R5FSS* chapter.  
For more information about ATCM and BTCM, see the *Tightly-Coupled Memories (TCM)* section within the *R5FSS* chapter.
- (4) This memory region is used by each CPU core to access the TCM/Cache memory space of other CPU cores.
- (5) Each R5FSS contains 16 KB i-cache and 16 KB d-cache. However, the system interconnect sees an 8 MB address range at ICACHE/DCACHE. Any core attempting to access more than 16 KB will wrap around and access the same cache multiple times.

## Control Module (CTRLMMR) Registers

---

The control module is the main controller for top-level device behavior in various states. Module contains registers for configuration, bootstrap (SOP) signals, I/O terminal pad multiplexing, clock selection, and many others. There are various control or (CTRLMMR) modules define in this device, and those module's registers are described in the following sections.

## 2.1 MMR Write Protection

All Control Module MMR have a protection mechanism which prevents spurious writes from changing register values. LOCK0\_KICK0 and LOCK0\_KICK1 registers are used for this purpose. The sequence to unlock these MMR is as follows:

1. Write exact unlock value (Table 2-1) to <Control Module>LOCK0\_KICK0:KEY field
2. Write exact unlock value (Table 2-1) to <Control Module>LOCK0\_KICK1:KEY field

The sequence to lock the MMR is as follows:

1. Write zero (or anyother value other than the unlock value)Table 2-1) to <Control Module>LOCK0\_KICK1:KEY field
2. Write zero (or anyother value other than the unlock value)Table 2-1) to <Control Module>LOCK0\_KICK0:KEY field

### Note

If the above sequence for locking the IOMUX is not followed, an AHB\_WRITE\_ERROR interrupt will occur (if enabled).

For example, to unlock Control Module MSS\_CTRL the sequence is as below:

1. Write 0x01234567 to MSS\_CTRL.LOCK0\_KICK0:KEY
2. Write 0xFEDCBA8 to MSS\_CTRL.LOCK0\_KICK1:KEY

To lock the Control Module MSS\_CTRL the sequence is as below:

1. Write 0x0 to MSS\_CTRL.LOCK0\_KICK1:KEY
2. Write 0x0 to MSS\_CTRL.LOCK0\_KICK0:KEY

Any writes to locked memory region will result in assertion of the MMR\_ACCESS\_ERR\_WR event by the respective control modules. This assertion can be enabled or disabled by writing the appropriate value to <Control Module>.INTR\_ENABLE.KICK\_ERR\_EN field.

The table below shows the values that must be written to the LOCK0\_KICK0 and LOCK0\_KICK1 registers to unlock the various Control modules' MMR.

**Table 2-1. Kick Protection Register Unlock Values**

| Protected Register | LockKick Register | Unlock Value |
|--------------------|-------------------|--------------|
| TOP_CTRL           | LOCK0_KICK0       | 0x01234567   |
|                    | LOCK0_KICK1       | 0xFEDCBA8    |
| MSS_CTRL           | LOCK0_KICK0       | 0x01234567   |
|                    | LOCK0_KICK1       | 0xFEDCBA8    |
| CONTROLSS_CTRL     | LOCK0_KICK0       | 0x01234567   |
|                    | LOCK0_KICK1       | 0xFEDCBA8    |
| TOP_RCM            | LOCK0_KICK0       | 0x01234567   |
|                    | LOCK0_KICK1       | 0xFEDCBA8    |
| MSS_RCM            | LOCK0_KICK0       | 0x01234567   |
|                    | LOCK0_KICK1       | 0xFEDCBA8    |
| IOMUX              | LOCK0_KICK0       | 0x83E70B13   |
|                    | LOCK0_KICK1       | 0x95A4F1E0   |

**Note**

To maintain that all registers from a given partition are write protected, software must always re-lock the protection mechanism after completing the register writes.

---

The kick protection registers described in this section are an exception and are not write protected by the protection mechanism.
