| 11:0  | EEE_PRESCALE | R/W  | 0h    | Energy Efficient Ethernet Prescale count load value - This value is loaded into the EEE pre-scale counter each time the pre-scale count decrements to zero. The EEE counters are enabled to decrement each time the pre-scale counter reaches zero (and the EEE counters are enabled to count time). If this value is zero then the EEE counters decrement on every clock. If this value is 0x001 then the counters decrement on every other clock (and so on). |

| 13:0  | TX_PRI6_MAXLEN | R/W  | 7E8h  | This value determines the maximum packet length that will be transmitted on priority 6 Ethernet egress for all Ethernet ports. The packet length compared to the maximum length value is the ingress packet length (not the actual egress packet length which is the length before VLAN addition or removal or any other egress processing). Packets on a priority that are larger than this value are dropped. |

| 13:0  | FH_MAXLEN | R/W  | 5EEh  | Port 0 Ingress Maximum Frame Length - This field determines the maximum length of a received frame. The reset value is 1518 (dec). Frames with byte counts greater than p0_fh_maxlen are long frames. Long frames with no errors are oversized frames. Long frames with CRC, code, or alignment error are jabber frames. The maximum value is 9604 (including VLAN) when the CPSW is configured with 1 = 4. When 1 = 1 the maximum value is 2024 (including VLAN). |

| 13:0  | RX_MAXLEN | R/W  | 5EEh  | RX Maximum Frame Length - This field determines the maximum length of a received frame. The reset value is 1518 (dec). Frames with byte counts greater than pn_rx_maxlen are long frames. Long frames with no errors are oversized frames. Long frames with CRC, code, or alignment error are jabber frames. The maximum value is 2024 (including VLAN). |

| 23:0  | COUNT    | R/W  | 0h    | EEE LPI to wake counter load value - When the port is in the transmit LPI state and the CLKSTOP_REQ signal is deasserted, this value is loaded into the LPI to wake counter. Transmit packet operations may begin (resume) when the LPI to wake count decrements to zero (on the pre-scale count). This is the time that the transmit must wait before transmit packet operations resume after wakeup. |

**Table 5-406. CPSW\_NC\_ETH\_MAC\_PN\_EST\_CONTROL\_REG\_K Register Field Descriptions**

| Bit   | Field           | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------|-----------------|------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:26 | RESERVED        | NONE | 0h    | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 25:16 | EST_FILL_MARGIN | R/W  | 0h    | EST Fill Margin - Sets the fill margin (in bytes) required to ensure that the Ethernet wire is clear so that the timed EST express packet can egress at the correct required time. Setting this value too high will put an unnecessary gap on the wire. Setting this value too low will cause the express packet to egress at a time later than intended (pushed out by non express traffic that did not have sufficient time to finish). |
| 15:9  | EST_PREMPT_COMP | R/W  | 0h    | EST Preempt Comparison Value - When the count in a zero allow is less than or equal to this value in bytes (times 8), preempt packets are cleared from the wire. This is the preempt clear margin value.                                                                                                                                                                                                                                  |
| 8     | EST_FILL_EN     | R/W  | 0h    | EST Fill Enable - Enable EST fill mode when set.                                                                                                                                                                                                                                                                                                                                                                                          |
| 7:5   | EST_TS_PRI      | R/W  | 0h    | EST Timestamp Express Priority - Selects the express priority that timestamp(s) will be generated on when pn_est_ts_onepri is set.                                                                                                                                                                                                                                                                                                        |
| 4     | EST_TS_ONEPRI   | R/W  | 0h    | EST Timestamp One Express Priority - When set, timestamps are only enabled on packets on the express priority selected by pn_est_ts_pri. When cleared to zero, express packet selection for timestamps is independent of priority.                                                                                                                                                                                                        |

**Table 5-406. CPSW\_NC\_ETH\_MAC\_PN\_EST\_CONTROL\_REG\_K Register Field Descriptions (continued)**

| Bit | Field        | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                               |
|-----|--------------|------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3   | EST_TS_FIRST | R/W  | 0h    | EST Timestamp First Express Packet only - Generate a timestamp only on the first selected express packet in each EST time interval when express timestamps are enabled. (If pn_est_ts_onepri is also set then the timestamp is generated only on the first packet on pn_est_ts_pri).                                                                                      |
| 2   | EST_TS_EN    | R/W  | 0h    | EST Timestamp Enable - Enable express timestamps (when est_en and pn_est_port_en are set).                                                                                                                                                                                                                                                                                |
| 1   | EST_BUFSEL   | R/W  | 0h    | EST Buffer Select - If pn_est_onebuf is cleared, this bit selects the upper (when set) or the lower (when cleared) 64-word fetch buffer. The actual fetch buffer used changes only at the start of the EST time interval and can be read in the Enet_Pn_FIFO_Status register pn_est_bufact bit.                                                                           |
| 0   | EST_ONEBUF   | R/W  | 0h    | EST One Fetch Buffer - When set indicates that all 128 fetch words are used in one buffer. When cleared, indicates that the 128 fetch words are split into two 64-word fetch buffers. The pn_est_bufsel selects the buffer to be used when pn_est_onebuf is cleared to zero. Two buffers allows software to change a buffer while the hardware is using the other buffer. |

**Table 5-469. CPSW\_NC\_ETH\_MAC\_PN\_MAC\_CONTROL\_REG\_K Register Field Descriptions**

| Bit   | Field     | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------|-----------|------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:25 | RESERVED  | NONE | 0h    | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 24    | RX_CMF_EN | R/W  | 0h    | RX Copy MAC Control Frames Enable - Enables MAC control frames to be transferred to memory. MAC control frames are normally acted upon (if enabled), but not copied/transferred to memory. MAC control frames that are pause frames will be acted upon if enabled in the MacControl register, regardless of the value of pn_rx_cmf_en. Frames transferred to memory due to pn_rx_cmf_en will have the mac_control bit set in their EOP buffer descriptor.<br>0 - MAC control frames are filtered (but are acted upon if enabled).<br>1 - MAC control frames are transferred to the host.                                                                                |
| 23    | RX_CSF_EN | R/W  | 0h    | RX Copy Short Frames Enable - Enables frames or fragments shorter than 64 bytes to be sent to the host. Frames transferred to the host due to pn_rx_csf_en will have the fragment or undersized bit set in their buffer descriptor. Short and fragment frame transfer is not guaranteed for all packet conditions and is best case only. Frames shorter than 33 bytes will be dropped in all cases. Fragments are short frames that contain CRC/align/code errors and undersized are short frames without errors. The pn_rx_cef_en bit must also be set to transfer fragment frames.<br>0 - Short frames are filtered.<br>1 - Short frames are transferred to the host. |

**Table 5-469. CPSW\_NC\_ETH\_MAC\_PN\_MAC\_CONTROL\_REG\_K Register Field Descriptions (continued)**

| Bit   | Field               | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------|---------------------|------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 22    | RX_CEF_EN           | R/W  | 0h    | RX Copy Error Frames Enable - Enables frames containing errors to be transferred to memory. The appropriate error bit will be set in the frame receive buffer descriptor. Frames containing errors will be filtered when this bit is not set.<br>0 - Frames containing errors are filtered.<br>1 - Frames containing errors are transferred to the host.                                                                                                                                                                                                                                            |
| 21    | TX_SHORT_GAP_LIM_EN | R/W  | 0h    | Transmit Short Gap Limit Enable - When set this bit limits the number of short gap packets transmitted to 100ppm. The pn_tx_short_gap_en bit must also be set. Each time a short gap packet is sent, a counter is loaded with 10,000 and decremented on each wireside clock. Another short gap packet will not be sent out until the counter decrements to zero. This mode is included to preclude the host from filling up the FIFO and sending every packet out with short gap which would violate the maximum number of packets per second allowed. This bit is used only with GMII (not XGMII). |
| 20    | EXT_TX_FLOW_EN      | R/W  | 0h    | External Transmit Flow Control Enable - Enables the pn_tx_flow_en to be selected from the EXT_TX_FLOW_EN input signal and not from the pn_tx_flow_en bit in this register.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 19    | EXT_RX_FLOW_EN      | R/W  | 0h    | External Receive Flow Control Enable - Enables the pn_rx_flow_en to be selected from the EXT_RX_FLOW_EN input signal and not from the pn_rx_flow_en bit in this register.                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 18    | EXT_EN              | R/W  | 0h    | External Control Enable - Enables the full duplex and gigabit mode to be selected from the FULLDUPLEX_IN and GIG_IN input signals and not from the pn_full duplex and pn_gig bits in this register. The FULLDUPLEX_MODE bit reflects the actual full duplex mode selected.                                                                                                                                                                                                                                                                                                                          |
| 17    | GIG_FORCE           | R/W  | 0h    | Gigabit Mode Force - This bit is used to force the Enet Mac into gigabit mode if the input GMII_MTCLK has been stopped by the PHY.<br>0 - GIG mode not forced<br>1 - GIG mode forced regardless of transmit clock                                                                                                                                                                                                                                                                                                                                                                                   |
| 16    | IFCTL_B             | R/W  | 0h    | Interface Control B - Intended as a general purpose output bit to be used to control external gaskets associated with the GMII (GMII to RGMII etc).                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 15    | IFCTL_A             | R/W  | 0h    | Interface Control A - Intended as a general purpose output bit to be used to control external gaskets associated with the GMII (GMII to RGMII etc).                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**Table 5-469. CPSW\_NC\_ETH\_MAC\_PN\_MAC\_CONTROL\_REG\_K Register Field Descriptions (continued)**

| Bit | Field      | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----|------------|------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5   | GMII_EN    | R/W  | 0h    | GMII Enable -<br>0 - GMII RX and TX held in reset.<br>1 - GMII RX and TX released from reset.<br>This bit should be written with a logic high before the other bits in this register are written.                                                                                                                                                                                                                                                                                                        |
| 4   | TX_FLOW_EN | R/W  | 0h    | Transmit Flow Control Enable - Determines if incoming pause frames are acted upon in full-duplex mode. Incoming pause frames are not acted upon in half-duplex mode regardless of this bit setting. The RX_MBP_Enable bits determine whether or not received pause frames are transferred to memory.<br>0 - Transmit Flow Control Disabled. Full-duplex mode - Incoming pause frames are not acted upon.<br>1 - Transmit Flow Control Enabled . Full-duplex mode - Incoming pause frames are acted upon. |
| 3   | RX_FLOW_EN | R/W  | 0h    | Receive Flow Control Enable -<br>0 - Receive Flow Control Disabled:<br>Half-duplex mode - No flow control generated collisions are sent. Full-duplex mode - No outgoing pause frames are sent.<br>1 - Receive Flow Control Enabled:<br>Half-duplex mode - Collisions are initiated when receive flow control is triggered.<br>Full-duplex mode - Outgoing pause frames are sent when receive flow control is triggered.                                                                                  |
| 2   | MTEST      | R/W  | 0h    | Manufacturing Test mode - This bit must be set to allow writes to the Backoff_Test and PauseTimer registers.                                                                                                                                                                                                                                                                                                                                                                                             |
| 1   | LOOPBACK   | R/W  | 0h    | Loop Back Mode - Loopback mode forces internal fullduplex mode regardless of whether the pn_fullduplex bit is set or not. The pn_loopback bit should be changed only when pn_gmii_en is de-asserted. Loopback is used only with GMII (not XGMII). Loopback is not compatible with timestamp operations (CPTS).<br>0 - Loop Back Mode disabled.<br>1 - Loop Back Mode enabled.                                                                                                                            |
| 0   | FULLDUPLEX | R/W  | 0h    | Full Duplex mode - Gigabit mode forces fullduplex mode regardless of whether the pn_fullduplex bit is set or not. The FULLDUPLEX_OUT output is the value of this register bit.<br>0 - half duplex mode.<br>1 - full duplex mode.                                                                                                                                                                                                                                                                         |

### 5.1.2.157 CPSW\_NC\_ETH\_MAC\_PN\_MAC\_STATUS\_REG\_K Register

#### 1 CPSW\_NC\_ETH\_MAC\_PN\_MAC\_STATUS\_REG\_K Register (Offset = 22334h) [reset = D0000000h]

Enet Port N Mac Status

Return to [Summary Table](#)

Offset = Base + (k \* 1000h); where k = 0 to 1d

**Table 5-470. Instance Table**

| Instance Name | Physical Address     |
|---------------|----------------------|
| CPSW0         | 5282 2334h + formula |

**Table 5-472. CPSW\_NC\_ETH\_MAC\_PN\_MAC\_STATUS\_REG\_K Register Field Descriptions**

| Bit   | Field           | Type | Reset | Description                                                                                                                                        |
|-------|-----------------|------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | IDLE            | R    | 1h    | Enet IDLE - The Ethernet port (express and preempt) is in the idle state when high.                                                                |
| 30    | E_IDLE          | R    | 1h    | Express MAC is idle when high                                                                                                                      |
| 29    | RESERVED        | NONE | 0h    | Reserved                                                                                                                                           |
| 28    | MAC_TX_IDLE     | R    | 1h    | Mac Transmit Idle - Both Preempt (if iet_incl) and Express MAC Transmit are in idle state. The transmit clock must be running for this to go idle. |
| 27    | TORF            | R    | 0h    | Top of receive FIFO flow control trigger occurred. This bit is write one to clear.                                                                 |
| 26:24 | TORF_PRI        | R    | 0h    | The lowest priority that caused top of receive FIFO flow control trigger since the last write to clear. This field is write 0x7 to clear.          |
| 23:16 | TX_PFC_FLOW_ACT | R    | 0h    | Receive Priority Based Flow Control Active (priority 7 down to 0).                                                                                 |
| 15:8  | RX_PFC_FLOW_ACT | R    | 0h    | Transmit Priority Based Flow Control Active (priority 7 down to 0).                                                                                |
| 7     | RESERVED        | NONE | 0h    | Reserved                                                                                                                                           |
| 6     | EXT_TX_FLOW_EN  | R    | 0h    | External Transmit Flow Control Enable - This is the value of the EXT_TX_FLOW_EN input bit.                                                         |
| 5     | EXT_RX_FLOW_EN  | R    | 0h    | External Receive Flow Control Enable - This is the value of the EXT_RX_FLOW_EN input bit.                                                          |

**Table 5-472. CPSW\_NC\_ETH\_MAC\_PN\_MAC\_STATUS\_REG\_K Register Field Descriptions (continued)**

| Bit | Field          | Type | Reset | Description                                                                                                                                                                                                                                                                                                             |
|-----|----------------|------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4   | EXT_GIG        | R    | 0h    | External GIG - This is the value of the EXT_GIG input bit.                                                                                                                                                                                                                                                              |
| 3   | EXT_FULLDUPLEX | R    | 0h    | External Fullduplex - This is the value of the EXT_FULLDUPLEX input bit.                                                                                                                                                                                                                                                |
| 2   | RESERVED       | NONE | 0h    | Reserved                                                                                                                                                                                                                                                                                                                |
| 1   | RX_FLOW_ACT    | R    | 0h    | Receive Flow Control Active - When asserted, indicates that receive flow control is enabled and triggered.                                                                                                                                                                                                              |
| 0   | TX_FLOW_ACT    | R    | 0h    | Transmit Flow Control Active - When asserted, this bit indicates that the pause time period is being observed for a received pause frame. No new transmissions will begin while this bit is asserted except for the transmission of pause frames. Any transmission in progress when this bit is asserted will complete. |

### 5.1.2.158 CPSW\_NC\_ETH\_MAC\_PN\_MAC\_SOFT\_RESET\_REG\_K Register

|-------|------------|------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | RESERVED   | NONE | 0h    | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 30:26 | PACEVAL    | R/W  | 0h    | Pacing Current Value - A non-zero value in this field indicates that transmit pacing is active. A transmit frame collision or deferral causes paceval to loaded with decimal 31, good frame transmissions (with no collisions or deferrals) cause paceval to be decremented down to zero. When paceval is nonzero, the transmitter delays 4 IPGs between new frame transmissions after each successfully transmitted frame that had no deferrals or collisions. Transmit pacing helps reduce capture effects improving overall network bandwidth. |
| 25:16 | RNDNUM     | R/W  | 0h    | Backoff Random Number Generator - This field allows the Backoff Random Number Generator to be read (or written in test mode only). This field can be written only when pn_mtest has previously been set. Reading this field returns the generator's current value. The value is reset to zero and begins counting on the clock after the de-assertion of reset.                                                                                                                                                                                   |
| 15:12 | COLL_COUNT | R    | 0h    | Collision Count - The number of collisions the current frame has experienced.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| 1:0  | POINTER  | R/W  | 0h    | InterVLAN location pointer - This field points to the InterVLAN location that will be read/written by accesses to Enet_Pn_InterVLANx_A/B/C (the InterVLAN locations are accessed by a mailbox). Valid pointer locations are 1 to x (where x is the number of locations - pointer location zero is unused). For example, if configured with 2 intervlan routes then only the values of 1 and 2 are valid. |

| 0    | SOFT_RESET | R/W  | 0h    | Software reset - Writing a one to this bit causes the entire CPSW logic to be reset. Software reset occurs when the DMA Controllers are in an idle state to avoid locking up the VBUSP bus. After writing a one to this bit, it may be polled to determine if the reset has occurred. If a one is read, the reset has not yet occurred. If a zero is read then reset has occurred. |

| 8    | FH_OWNERSHIP   | R/W  | 0h    | CPDMA FHost Ownership Write Bit Value.<br>0 - The CPDMA writes the FHost buffer descriptor ownership bit to zero at the end of packet processing as specified in CPPI 3.0.<br>1 - The CPDMA writes the FHost buffer descriptor ownership bit to one at the end of packet processing. Users who do not use the ownership mechanism can use this mode to preclude the necessity of software having to set this bit each time the buffer descriptor is used. Software must set this bit when building the packet chain. |
| 7    | TH_CH_OVERRIDE | R/W  | 0h    | CPDMA THost Channel Classification Match Override Enable<br>0 - The THost channel is not overridden with the ALE classification match.<br>1 - The THOST channel is overridden with the lower 3-bits of the ALE classification match value (if a classification match occurred).                                                                                                                                                                                                                                      |
| 6    | TH_TS_ENCAP    | R/W  | 0h    | CPDMA THost Packet Timestamp Encapsulation<br>0 - THost packets do not contain a 64-bit timestamp<br>1 - THost packets contain a 64-bit timestamp prepended to the packet data (32-bit lword first).                                                                                                                                                                                                                                                                                                                 |
| 5    | TH_VLAN_ENCAP  | R/W  | 0h    | CPDMA THost Packet VLAN Encapsulation<br>0 - THost packets are not VLAN encapsulated<br>1 - THost packets are VLAN encapsulated                                                                                                                                                                                                                                                                                                                                                                                      |

**Table 5-544. CPSW\_NC\_CPDMA\_REGS\_CONTROL\_REG Register Field Descriptions (continued)**

| Bit | Field           | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----|-----------------|------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4   | TH_CEF          | R/W  | 0h    | CPDMA THost Copy Error Frames Enable - Enables THost DMA overrun frames to be transferred to memory (up to the point of buffer overrun). The overrun error bit will be set in the frame EOP buffer descriptor. Overrun frame data will be filtered when thost_cef is not set. THost frames with other error bits set are not affected by this bit. This is related only to frames that overrun on the THost DMA due to buffer limitations.<br>0 - Frames containing overrun errors are filtered.<br>1 - Frames containing overrun errors are transferred to memory. |
| 3   | CMD_IDLE        | R/W  | 0h    | CPDMA Command Idle<br>0 - Idle not commanded<br>1 - Idle Commanded (read idle in CPDMA_Status register)                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 2   | TH_OFFLEN_BLOCK | R/W  | 0h    | CPDMA THost Offset/Length word write block<br>0 - Do not block the DMA writes to the THost buffer descriptor offset/buffer length word. The offset/buffer length word is written as specified in CPPI 3.0.<br>1 - Block all CPDMA DMA controller writes to the THost buffer descriptor offset/buffer length words during CPPI packet processing. When this bit is set, the CPDMA will never write the third word to any THost buffer descriptor.                                                                                                                    |
| 1   | TH_OWNERSHIP    | R/W  | 0h    | CPDMA THost Ownership Write Bit Value<br>0 - The CPDMA writes the THost buffer descriptor ownership bit to zero at the end of packet processing as specified in CPPI 3.0.<br>1 - The CPDMA writes the THost buffer descriptor ownership bit to one at the end of packet processing. Users who do not use the ownership mechanism can use this mode to preclude the necessity of software having to set this bit each time the buffer descriptor is used. Software must set this bit when building the packet chain.                                                 |
| 0   | FH_PTYPE        | R/W  | 0h    | CPDMA FHost Queue Priority Type<br>0 - The queue uses a round robin scheme to select the next channel.<br>1 - The queue uses a fixed (channel 7 highest priority) priority scheme to select the next channel.                                                                                                                                                                                                                                                                                                                                                       |

| 11:0  | TH_BUFFER_OFFSET | R/W  | 0h    | CPDMA THost Buffer Offset Value - The thost_buffer_offset will be written by the port into each frame SOP buffer descriptor buffer_offset field. The frame data will begin after the thost_buffer_offset value of bytes. A value of 0x0 indicates that there are no unused bytes at the beginning of the data and that valid data begins on the first byte of the buffer. A value of 0xF (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. This value is used for all channels. |

| 31:0 | DMA_IN_VECTOR | R    | 0h    | The value of CPDMA_In_Vector is reset to zero, but will change to the IN_VECTOR input bus value one clock after reset is deasserted. Thereafter, this value will change to a new IN_VECTOR input value one clock after the IN_VECTOR value changes. |

### 5.1.2.190 CPSW\_NC\_CPDMA\_INT\_EOI\_VECTOR\_REG Register

#### 1 CPSW\_NC\_CPDMA\_INT\_EOI\_VECTOR\_REG Register (Offset = 34094h) [reset = 0h]

The CPDMA\_EOI\_VECTOR(4:0) output bus reflects the value written to this location one VBUSP\_GCLK cycle after a write to this location. The EOI\_WR signal is asserted for a single clock cycle after a latency of two VBUSP\_GCLK cycles when a write is performed to this location.

| 15:0  | TH0_FREEBUFFER | R/W  | 0h    | This field contains the count of host free buffers available. The th(0..7)_pendthresh value is compared with this field to determine if the THost threshold pending interrupt should be asserted (if enabled). This is a write to increment field. This field rolls over to zero on overflow. If THost threshold pending interrupts are used, the host must initialize this field to the number of available buffers (one register per channel). The port decrements (by the number of buffers in the frame) the associated channel register for each frame. This is a write to increment field. The host must write this field with the number of buffers that have been freed due to host processing. |

| 15:0  | TH1_FREEBUFFER | R/W  | 0h    | This field contains the count of host free buffers available. The th(0..7)_pendthresh value is compared with this field to determine if the THost threshold pending interrupt should be asserted (if enabled). This is a write to increment field. This field rolls over to zero on overflow. If THost threshold pending interrupts are used, the host must initialize this field to the number of available buffers (one register per channel). The port decrements (by the number of buffers in the frame) the associated channel register for each frame. This is a write to increment field. The host must write this field with the number of buffers that have been freed due to host processing. |

| 15:0  | TH4_FREEBUFFER | R/W  | 0h    | This field contains the count of host free buffers available. The th(0..7)_pendthresh value is compared with this field to determine if the THost threshold pending interrupt should be asserted (if enabled). This is a write to increment field. This field rolls over to zero on overflow. If THost threshold pending interrupts are used, the host must initialize this field to the number of available buffers (one register per channel). The port decrements (by the number of buffers in the frame) the associated channel register for each frame. This is a write to increment field. The host must write this field with the number of buffers that have been freed due to host processing. |

| 15:0  | TH7_FREEBUFFER | R/W  | 0h    | This field contains the count of host free buffers available. The th(0..7)_pendthresh value is compared with this field to determine if the THost threshold pending interrupt should be asserted (if enabled). This is a write to increment field. This field rolls over to zero on overflow. If THost threshold pending interrupts are used, the host must initialize this field to the number of available buffers (one register per channel). The port decrements (by the number of buffers in the frame) the associated channel register for each frame. This is a write to increment field. The host must write this field with the number of buffers that have been freed due to host processing. |

| 0    | TS_PUSH  | W    | 0h    | Time stamp event push - When a logic high is written to this bit a time stamp event is pushed onto the event FIFO. The time stamp value is the time of the write of this register, not the time of the event read. The time stamp value can then be read on interrupt via the event registers. Software should not push a second time stamp event onto the event FIFO until the first time stamp value has been read from the event FIFO (there should be only one time stamp event in the event FIFO at any given time). This bit is write only and always reads zero. |

| 0    | EVENT_POP | W    | 0h    | Event Pop - When a logic high is written to this bit an event is popped off the event FIFO. The event FIFO pop occurs as part of the interrupt process after the event has been read from the Event_0-3 registers. Popping an event discards the event and causes the next event, if any, to be moved to the top of the FIFO ready to be read by software on interrupt. |

| 31:0 | TS_LOAD_VAL | R/W  | 0h    | Time Stamp Load high Value - Writing the ts_load_en bit causes the value contained in this register (and the ts_load[63:0]) to be written into the time stamp. The time stamp value is read by initiating a time stamp push event, not by reading this register. When reading this register, the value read is not the time stamp, but is the value that was last written to this register. This value is unused in 32-bit mode. |

### 5.1.2.358 CPSW\_NC\_CPTS\_TS\_COMP\_HIGH\_VAL\_REG Register

|------|------------------|------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | TS_COMP_HIGH_VAL | R/W  | 0h    | Time Stamp Comparison High Value - Writing a non-zero value to the TS_Comp_Length[31:0] register causes a pulse of TS_Comp_Length RCLK periods on the TS_COMP output and a comparison event when the time_stamp counter value is equivalent to ts_comp_val[63:0]. This value is unused in 32-bit mode. The upper 32-bits in this register should be written before the lower 32-bits in the TS_Comp_Low register. |

### 5.1.2.379 CPSW\_NC\_ALE\_STATUS Register

#### 1 CPSW\_NC\_ALE\_STATUS Register (Offset = 3E004h) [reset = 80000400h]

The ALE status provides information on the ALE configuration and state. The ramdepth is used to determine how IPv6 entries are stored in the table. IPv6 entries are stored in two entries where IPv6 Entry Hi is designated by the odd slice index and Lo is designated by the even slice index. The slice index is above the ram depth like {SliceIndex,RamIndex}. So, for a 64 deep RAM index of 0x005, the Hi portion of the IPv6 entry is located at 0x005(0x040) and the Lo portion is located at 0x005 & (~0x040).

|-------|-------------|------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | ENABLE_ALE  | R/W  | 0h    | Enable ALE<br>0 - Drop all packets<br>1 - Enable ALE packet processing                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 30    | CLEAR_TABLE | R/W  | 0h    | Clear ALE address table - Setting this bit causes the ALE hardware to write all table bit values to zero. Software must perform a clear table operation as part of the ALE setup/configuration process. Setting this bit causes all ALE accesses to be held up for 64 clocks while the clear is performed. Access to all ALE registers will be blocked (wait states) until the 64 clocks have completed. This bit cannot be read as one because the read is blocked until the clear table is completed at which time this bit is cleared to zero. |
| 29    | AGE_OUT_NOW | R/W  | 0h    | Age Out Address Table Now - Setting this bit causes the ALE hardware to remove (free up) any ageable table entry that does not have a set touch bit. This bit is cleared when the age out process has completed. This bit may be read. The age out process takes four times the number of table entries clock cycles (4096 cycles for 1K addresses) best case (no ale packet processing during ageout) and sixty five times the number of table entries clock cycles (66560 cycles for 1K addresses) absolute worst case.                         |

| 25:24 | MIRROR_DP         | R/W  | 0h    | Mirror Destination Port - This field defines the port to which destination traffic destined will be duplicated. That is all traffic that is forwarded to this port will also be mirrored to the mirror_top port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 23:21 | UPD_BW_CTRL       | R/W  | 0h    | The upd_bw_ctrl field allows for up to 8 times the rate in which adds, updates, touches, writes, and aging updates can occur. At frequencies of 350Mhz, the table update rate should be at it lowest or 5 Million updates per second. When operating the switch core at frequencies or above, the upd_bw_ctrl can be programmed more aggressive. If the upd_bw_ctrl is set but the frequency of the switch subsystem is below the associated value, ALE will drop packets due to insufficient time to complete lookup under high traffic loads.<br>0 - 350Mhz, 5M<br>1 - 359Mhz, 11M<br>2 - 367Mhz, 16M<br>3 - 375Mhz, 22M<br>4 - 384Mhz, 28M<br>5 - 392Mhz, 34M<br>6 - 400Mhz, 39M<br>7 - 409Mhz, 45M |
| 20:18 | RESERVED          | NONE | 0h    | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 17:16 | MIRROR_TOP        | R/W  | 0h    | Mirror To Port - This field defines the destination port for the mirror traffic. If the traffic is received or transmitted on the mirror destination port it will not be duplicated. Traffic defined as mirror traffic only may be dropped by the switch due to congestion.                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 15    | UPD_STATIC        | R/W  | 0h    | Update Static Entries - A static Entry is an entry that is not agable. When clear this bit will prevent any static entry (agable bit clear) from being updated due to port change. When set it allows static entries (agable bit clear) to update the source port if required. This bit should normally be '0' for most switch configurations.                                                                                                                                                                                                                                                                                                                                                         |
| 14    | LRN_HOST_DST      | R/W  | 0h    | Learn Host Destination - This field is set to only learn unicast packet source addresses that are destined to the host port. This bit is only valid for 3 port switches and allows the ALE table to only contain addresses the host port is concerned about. This bit is affectively disabled when en_host_uni_flood is set since any unknown unicast is also sent to the host port for extended bridging operations.                                                                                                                                                                                                                                                                                  |
| 13    | UVLAN_NO_LEARN    | R/W  | 0h    | Unknown VLAN No Learn - This field when set will prevent source addresses of unknown VLAN IDs from being automatically added into the look up table if learning is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 12    | MIRROR_MEN        | R/W  | 0h    | Mirror Match Entry Enable - This field enables the match mirror option. When this bit is set any traffic whose destination, source, VLAN or OUI matches the mirror_midx entry index will have that traffic also sent to the mirror_top port.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 11    | MIRROR_DEN        | R/W  | 0h    | Mirror Destination Port Enable - This field enables the destination port mirror option. When this bit is set any traffic destined for the mirror_dp port will have its transmit traffic also sent to the mirror_top port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 10    | MIRROR_SEN        | R/W  | 0h    | Mirror Source Port Enable - This field enables the source port mirror option. When this bit is set any port with the pX_mirror_sp set in the ALE Port Control registers set will have its received traffic also sent to the mirror_top port.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 9     | RESERVED          | NONE | 0h    | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

**Table 5-1141. CPSW\_NC\_ALE\_CONTROL Register Field Descriptions (continued)**

| Bit | Field             | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----|-------------------|------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 6   | ENABLE_VID0_MODE  | R/W  | 0h    | Enable VLAN ID = 0 Mode<br>0 - Process the priority tagged packet with VID = PORT_VLAN[11:0].<br>1 - Process the priority tagged packet with VID = 0.                                                                                                                                                                                                                                                                                        |
| 5   | ENABLE_OUI_DENY   | R/W  | 0h    | Enable OUI Deny Mode - When set, any packet with a non-matching OUI source address will be dropped to the host unless the packet destination address matches a supervisory destination address table entry. When cleared, any packet source address matching an OUI address table entry will be dropped to the host unless the destination address matches with a supervisory destination address table entry.                               |
| 4   | ENABLE_BYPASS     | R/W  | 0h    | ALE Bypass - When set, packets received on non-host ports are sent to the host. It is expected that packets from the host are directed to the particular port.<br>0 - no bypass<br>1 - bypass the ALE                                                                                                                                                                                                                                        |
| 3   | BCAST_MCAST_CTL   | R/W  | 0h    | Rate Limit Transmit mode<br>0 - Broadcast and multicast rate limit counters are received port based<br>1 - Broadcast and multicast rate limit counters are transmit port based                                                                                                                                                                                                                                                               |
| 2   | ALE_VLAN_AWARE    | R/W  | 0h    | ALE VLAN Aware - Determines how traffic is forwarded using VLAN rules.<br>0 - Simple switch rules, packets forwarded to all ports for unknown destinations.<br>1 - VLAN Aware rules, packets forwarded based on VLAN members                                                                                                                                                                                                                 |
| 1   | ENABLE_AUTH_MODE  | R/W  | 0h    | Enable MAC Authorization Mode - Mac authorization mode requires that all table entries be made by the host software. There is no auto learning of addresses in authorization mode and the packet will be dropped if the source address is not found (and the destination address is not a multicast address with the super table entry bit set).<br>0 - The ALE is not in MAC authorization mode<br>1 - The ALE is in MAC authorization mode |
| 0   | ENABLE_RATE_LIMIT | R/W  | 0h    | Enable Broadcast and Multicast Rate Limit<br>0 - Broadcast/Multicast rates not limited<br>1 - Broadcast/Multicast packet reception limited to the port control register rate limit fields.                                                                                                                                                                                                                                                   |

### 5.1.2.381 CPSW\_NC\_ALE\_CTRL2 Register

#### 1 CPSW\_NC\_ALE\_CTRL2 Register (Offset = 3E00Ch) [reset = 0h]

The ALE Control 2 Register is used to set the extended features used for all ports.

**Table 5-1144. CPSW\_NC\_ALE\_CTRL2 Register Field Descriptions**

| Bit | Field        | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                |
|-----|--------------|------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31  | TRK_EN_DST   | R/W  | 0h    | Trunk Enable Destination Address - This field enables the destination MAC address to be used with the hash function $G(X) = 1 + X + X^3$ and affect the trunk port transmit link determination.                                                                                                                                                            |
| 30  | TRK_EN_SRC   | R/W  | 0h    | Trunk Enable Source Address - This field enables the source MAC address to be used with the hash function $G(X) = 1 + X + X^3$ and affect the trunk port transmit link determination.                                                                                                                                                                      |
| 29  | TRK_EN_PRI   | R/W  | 0h    | Trunk Enable Priority - This field enables the VLAN Priority bits to be used with the hash function $G(X) = 1 + X + X^3$ and affect the trunk port transmit link determination. In the event that DSCP mapping is enabled and there is no VLAN the DSCP priority will be used. For all other non IP frames without VLAN the port default priority is used. |
| 28  | RESERVED     | NONE | 0h    | Reserved                                                                                                                                                                                                                                                                                                                                                   |
| 27  | TRK_EN_IVLAN | R/W  | 0h    | Trunk Enable Inner VLAN - This field enables the inner VLAN ID value (C-VLANID) to be used with the hash function $G(X) = 1 + X + X^3$ and affect the trunk port transmit link determination.                                                                                                                                                              |
| 26  | RESERVED     | NONE | 0h    | Reserved                                                                                                                                                                                                                                                                                                                                                   |
| 25  | TRK_EN_SIP   | R/W  | 0h    | Trunk Enable Source IP Address - This field enables the source IP address to be used with the hash function $G(X) = 1 + X + X^3$ and affect the trunk port transmit link determination. This feature supports No tag, Priority tagged, VLAN tagged, Q-in-Q double tagging for both IPV6 and IPV4.                                                          |

**Table 5-1144. CPSW\_NC\_ALE\_CTRL2 Register Field Descriptions (continued)**

| Bit   | Field          | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------|----------------|------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 24    | TRK_EN_DIP     | R/W  | 0h    | Trunk Enable Destination IP Address - This field enables the destination IP address to be used with the hash function $G(X) = 1 + X + X^3$ and affect the trunk port transmit link determination. This feature supports No tag, Priority tagged, VLAN tagged, Q-in-Q double tagging for both IPV6 and IPV4.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 23    | DROP_BADLEN    | R/W  | 0h    | Drop Bad Length will drop any packet that the 802.3 length field is larger than the packet. Ethertypes 0-1500 are 802.3 lengths, all others are Ether types.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 22    | NODROP_SRCMCST | R/W  | 0h    | No Drop Source Multicast will disable the dropping of any source address with the multicast bit set.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 21    | DEFNOFRAG      | R/W  | 0h    | Default No Frag field will cause an IPv4 fragmented packet to be dropped if a VLAN entry is not found.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 20    | DEFLMTNXTHDR   | R/W  | 0h    | Default limit next header field will cause an IPv4 protocol or IPv6 next header packet to be dropped if a VLAN entry is not found and the protocol or next header does not match the ALE_NXT_HDR register values.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 19    | RESERVED       | NONE | 0h    | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 18:16 | TRK_BASE       | R/W  | 0h    | Trunk Base - This field is the hash formula starting value. Changing this value will cause the packet distribution on trunk ports to be changed. If all the trk_en_dst, trk_en_src, trk_en_pri and trk_en_vlan are '0', this value is used as the distribution index. That is a '0' will select the 1st bit of an 'N' link trunk, a '1' will select the second, etc. Below is the distribution across the trunk links. The first number in the italic sequence indicates the traffic is sent to the lowest numbered port of a trunk group. For example if you have a 3 port trunk, the hash result 0 will go to the base port (0), hash result 1 will go to the highest port of the trunk group (2), hash result 2 will go to the middle port (1), etc.<br>1 - 00000000<br>2 - 01010101<br>3 - 02102102<br>4 - 03210321 |
| 15    | MULTIHOST      | R/W  | 0h    | The ~multihost allows host traffic to be sent back to the host if the DA is market for the host port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| 8:0   | MIRROR_MIDX    | R/W  | 0h    | Mirror Index - This field is the ALE lookup table entry index that when a match occurs will cause this traffic to be mirrored to the mirror_top port. That is any VLAN, ONU or address with or without VLAN can be selected for traffic mirroring.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

### 5.1.2.382 CPSW\_NC\_ALE\_PRESCALE Register

#### 1 CPSW\_NC\_ALE\_PRESCALE Register (Offset = 3E010h) [reset = 0h]

The ALE Prescale Register is used to set the Broadcast and Multicast rate limiting prescaler value.

| 19:0  | ALE_PRESCALE | R/W  | 0h    | ALE Prescale - The input clock is divided by this value for use in the multicast/broadcast rate limiters. The minimum operating value is 0x10. The prescaler is off when the value is zero. |

### 5.1.2.383 CPSW\_NC\_ALE\_AGING\_CTRL Register

#### 1 CPSW\_NC\_ALE\_AGING\_CTRL Register (Offset = 3E014h) [reset = 0h]

The ALE Aging Control sets the aging interval which will cause periodic aging to occur. This value specifies the minimum time between aging starts.

### 5.1.2.384 CPSW\_NC\_ALE\_NXT\_HDR Register

#### 1 CPSW\_NC\_ALE\_NXT\_HDR Register (Offset = 3E01Ch) [reset = 0h]

The ALE Next Header is used to limit the IPv6 Next header or IPv4 Protocol values found in the IP header. It is enabled via the ~iLmtNxtHdr bit in the VLAN entry. All four ~iip\_nxt\_hdr0-3 are compared when enabled, so if only one is required, set them all to the one value to be tested.

### 5.1.2.385 CPSW\_NC\_ALE\_TBLCTL Register

#### 1 CPSW\_NC\_ALE\_TBLCTL Register (Offset = 3E020h) [reset = 0h]

The ALE table control register is used to read or write that ALE table entries. After writing to this register any read or write to any ALE register will be stalled until the read or write operation completes.

### 5.1.2.389 CPSW\_NC\_ALE\_I0\_PORTCTL0 Register

#### 1 CPSW\_NC\_ALE\_I0\_PORTCTL0 Register (Offset = 3E040h) [reset = 0h]

The ALE Port Control Register sets the port specific modes of operation.

**Table 5-1168. CPSW\_NC\_ALE\_I0\_PORTCTL0 Register Field Descriptions**

| Bit   | Field                      | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------|----------------------------|------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:24 | I0_REG_P0_BCAST_LIMIT      | R/W  | 0h    | Broadcast Packet Rate Limit - Each prescale pulse loads this field into the port broadcast rate limit counter. The port counters are decremented with each packet received or transmitted depending on whether the mode is transmit or receive. If the counters decrement to zero, then further packets are rate limited until the next prescale pulse.<br>Broadcast rate limiting is enabled by a non-zero value in this field.                                                                                                  |
| 23:16 | I0_REG_P0_MCAST_LIMIT      | R/W  | 0h    | Multicast Packet Rate Limit - Each prescale pulse loads this field into the port multicast rate limit counter. The port counters are decremented with each packet received or transmitted depending on whether the mode is transmit or receive. If the counters decrement to zero, then further packets are rate limited until the next prescale pulse.<br>Multicast rate limiting is enabled by a non-zero value in this field. The mcast_limit is the number of Multicast packets that will be forwarded per ale_prescale time. |
| 15    | I0_REG_P0_DROP_DOUBLE_VLAN | R/W  | 0h    | Drop Double VLAN - When set cause any received packet with double VLANs to be dropped. That is if there are two ctag or two stag fields in the packet it will be dropped.                                                                                                                                                                                                                                                                                                                                                         |
| 14    | I0_REG_P0_DROP_DUAL_VLAN   | R/W  | 0h    | Drop Dual VLAN - When set will cause any received packet with dual VLAN stag followed by ctag to be dropped.                                                                                                                                                                                                                                                                                                                                                                                                                      |

**Table 5-1168. CPSW\_NC\_ALE\_I0\_PORTCTL0 Register Field Descriptions (continued)**

| Bit | Field                       | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----|-----------------------------|------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 13  | I0_REG_P0_MACONLY_CAF       | R/W  | 0h    | Mac Only Copy All Frames - When set a Mac Only port will transfer all received good frames to the host. When clear a Mac Only port will transfer packets to the host based on ALE destination address lookup operation (which operates more like an Ethernet Mac). A Mac Only port is a port with maonly set.                                                                                                                                                                                                                                                                           |
| 12  | I0_REG_P0_DIS_PAUTH_MOD     | R/W  | 0h    | Disable Port authorization - When set will allow unknown addresses to arrive on a switch in authorization mode. It is intended for device to device network connection on ports which do not require MACSEC encryption.                                                                                                                                                                                                                                                                                                                                                                 |
| 11  | I0_REG_P0_MACONLY           | R/W  | 0h    | MAC Only - When set enables this port be treated like a MAC port for the host. All traffic received is only sent to the host. The host must direct traffic to this port as the lookup engine will not send traffic to the ports with the p0_maonly bit set and the p0_no_learn also set. If p0_maonly bit is set and the p0_no_learn is not set, the host can send non-directed packets that can be sent to the destination of a MacOnly port. It is also possible that The host can broadcast to all ports including MacOnly ports in this mode.                                       |
| 10  | I0_REG_P0_TRUNKEN           | R/W  | 0h    | Trunk Enable - This field is used to enable a port into a trunk. Any port can be used as a trunk port, any two or more ports with the p0_trunken its set and having the same p0_trunknum will be placed in the same trunk. There is no requirement for trunk ports to be adjacent. If all ports are enabled in the same trunk, no traffic can flow as traffic received within a trunk is never trasnmitted out the same trunk. If only a single port is a member of a trunk, it looks like a normal port with exception of entries in the look up table will be noted as a trunk entry. |
| 9:8 | I0_REG_P0_TRUNKNUM          | R/W  | 0h    | Trunk Number - This field is used as the trunk number when the p0_trunken is also set. Ports with the same trunk number that have the p0_trunken also set will have traffic distributed within the trunk based on the result of the hash function described above.                                                                                                                                                                                                                                                                                                                      |
| 7   | I0_REG_P0_MIRROR_SP         | R/W  | 0h    | Mirror Source Port - This field enables the source port mirror option. When this bit is set any traffic received on the port with the reg_p0_mirror_sp bit set will have its received traffic also sent to the mirror_top port.                                                                                                                                                                                                                                                                                                                                                         |
| 6   | RESERVED                    | NONE | 0h    | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 5   | I0_REG_P0_NO_SA_UP_DATE     | R/W  | 0h    | No Source Address Update - When set will not update the source addresses for this port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 4   | I0_REG_P0_NO_LEARN          | R/W  | 0h    | No Learn - When set will not learn the source addresses for this port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 3   | I0_REG_P0_VID_INGRESS_CHECK | R/W  | 0h    | VLAN Ingress Check - When set if a packet received is not a member of the VLAN, the packet will be dropped.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| 2:0  | OAM_LB_CTRL | R/W  | 0h    | The oam_lb_ctrl allows any port to be put into OAM loopback, that is any packet received will be returned to the same port with an egressop of 0xFF which swaps the source and destination address. BPDUs will still flow through as normal so that OAM can be remotely requested and disabled. |

### 5.1.2.397 CPSW\_NC\_ALE\_EGRESSOP Register

#### 1 CPSW\_NC\_ALE\_EGRESSOP Register (Offset = 3E0FCh) [reset = 0h]

The Egress Operation register allows enabled classifiers with any match like IPSA or IPDA match to use the CPSW Egress Packet Operations Inter VLAN Routing sub functions. If the packet was destined for the host or is destined to any port without any errors, but matches a classifier that has a programmed egress opcode, it will be forwarded to the destination ports where the destination ports will use the thier egress opcode entry to modify the packet. InterVLAN Routing and mirroring need to be understood, they are orthogonal functions. Care must be taken not to violate VLAN rules as this can redirect packets based on classifier matches.

### 5.1.2.403 CPSW\_NC\_ALE\_POLICECFG6 Register

#### 1 CPSW\_NC\_ALE\_POLICECFG6 Register (Offset = 3E118h) [reset = 0h]

The PIR counter is a 37 bit internal counter where ~ipir\_idle\_inc\_val is added every clock and the frame size << 18 is subtracted at EOF if not RED at LUT time. If the counter is negative the packet will be marked RED, else it can be YELLOW or GREEN based on the CIR counter. If only this counter is used (aka cir\_idle\_inc\_val==0) Packet are marked RED or GREEN based on PIR counter only.

| 31:0 | CIR_IDLE_INC_VAL | R/W  | 0h    | Committed Information Idle Increment Value - The number added to the CIR counter every clock cycle. If zero the CIR counter is disabled and packets will never be marked or processed as YELLOW. |

### 5.1.2.405 CPSW\_NC\_ALE\_POLICETBLCTL Register

#### 1 CPSW\_NC\_ALE\_POLICETBLCTL Register (Offset = 3E120h) [reset = 0h]

The Policing Table Control is used to read or write the selected policing/classifier entry. The selected policing/classifier entry is only read or written after this register is written based on the value of the ~iwrite\_enable bit.

| 4:0  | POL_TBL_IDX  | R/W  | 0h    | Policer Entry Index - This field specifies the policing/classifier entry to be read or written. When writing to this field without setting the write_enable=1 will cause the selected policing/classifier entry to be loaded into the POLICECFG0-7 registers. When writing to this field with setting the write_enable=1 will cause the selected policing/classifier entry to be updated from the POLICECFG0-7 registers. |

### 5.1.2.406 CPSW\_NC\_ALE\_POLICECONTROL Register

#### 1 CPSW\_NC\_ALE\_POLICECONTROL Register (Offset = 3E124h) [reset = 0h]

The Control Enables color marking as well as internal ALE packet dropping rules.

### 5.1.2.407 CPSW\_NC\_ALE\_POLICETESTCTL Register

#### 1 CPSW\_NC\_ALE\_POLICETESTCTL Register (Offset = 3E128h) [reset = 0h]

The Policing Test Control enables the ability to determine which policing entry has been hit and whether they reported a red or yellow rate condition.

### 5.1.2.410 CPSW\_NC\_ALE\_THREADMAPCTL Register

#### 1 CPSW\_NC\_ALE\_THREADMAPCTL Register (Offset = 3E138h) [reset = 0h]

The THREAD Mapping Control register allows the highest matched classifier to return a particular thread ID for traffic sent to the host. This allows particular classifier matched traffic to be placed an a particular hosts queue.

#### 5.3.2 ECC\_AGGR Registers

#### ECC\_AGGR Registers

### 5.3.2.1 ECC\_AGGR\_AGGR\_REVISION Register

#### 1 ECC\_AGGR\_AGGR\_REVISION Register (Offset = 0h) [reset = 66A0C200h]

The Revision Register contains the major and minor revisions for the ECC aggregator module. It does not support byte accesses.

#### 5.4.2 ELM Registers

#### ELM Registers

### 5.4.2.1 ELM\_REVISION Register

#### 1 ELM\_REVISION Register (Offset = 0h) [reset = 20h]

This register contains the IP revision code.  
(A write to this register has no effect, the same as the reset).

### 5.4.2.2 ELM\_SYSSTS Register

#### 1 ELM\_SYSSTS Register (Offset = 14h) [reset = 0h]

Internal Reset monitoring (OCP domain)

Undefined since:

From HW perspective reset state is 0

From SW user perspective when module is accessible is 1

### 5.4.2.3 ELM\_IRQSTS Register

#### 1 ELM\_IRQSTS Register (Offset = 18h) [reset = 0h]

Interrupt status. This register doubles as a status register for the error location processes.

### 5.4.2.7 ELM\_SYNDROME\_FRAGMENT\_0 Register

#### 1 ELM\_SYNDROME\_FRAGMENT\_0 Register (Offset = 400h) [reset = 0h]

Input syndrome polynomial bits 0 to 31.

Return to [Summary Table](#)

Offset = Base + (j \* 40h); where j = 0 to 7d

**Table 5-1413. Instance Table**

| Instance Name | Physical Address     |
|---------------|----------------------|
| ELM0          | 527F 0400h + formula |

|-----|-------|------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3:0 | KEY   | R/W  | 0h    | <p>This field controls behavior of the Error Pin. Note, during reset the field is 4'b0000, but the Error Pin is asserted (active low). Immediately after reset, the Error Pin de-asserts. This field is only reset by a Power-On-Reset (not warm reset).</p> <p>4'b0000 : Normal Mode - Error Pin will activate when an enabled Error Event occurs</p> <p>4'b1010 : Force Error Mode - Forces the Error Pin active. To clear the Error Pin (return to the ESM_IDLE state) write this field back to Normal Mode (Writing a CLEAR event will also work). You may only write to Force Error Mode while in IDLE. Attempting Force Error while in another state will have no effect</p> <p>4'b0101 : CLEAR Event - generates a CLEAR event to the ESM state machine. key will return to Normal Mode (4'b0000) on the next cycle.</p> <p>All Other Values - Normal Mode. Writing any of these values will have no effect. Reading any of these values indicate that one or more bits have experienced a single event upset and software should write the field back to 4'b0000. The ESM will continue to operate in Normal Mode</p> |

### 5.5.2.15 ESM\_PIN\_STS Register

#### 1 ESM\_PIN\_STS Register (Offset = 44h) [reset = 0h]

This register reflects the status of the error\_pin\_n output.

| 31:24 | RESERVED | NONE | 0h     | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 23:0  | COUNT    | R    | 186A0h | This field indicates the current value of the PWM High Time Interval Counter. The reset value is the 24'h0186A0. If pwm_en is set to PWM mode, then this register is enabled. This register is reloaded to the PWM high PIN_CNTR_PRE.count value when the error output pin toggles high. It will decrement by 1 each cycle when the error output pin is high. Once the counter has reached 0, the error output pin will toggle low. This field is only reset by a Power-On-Reset (not warm reset). A global soft reset will set this field to 24'h0186A0 |

### 5.5.2.19 ESM\_PWMH\_PIN\_CNTR\_PRE Register

#### 1 ESM\_PWMH\_PIN\_CNTR\_PRE Register (Offset = 54h) [reset = 186A0h]

This register contains the value that is loaded in to the Error PWM High Counter.

| 23:0  | COUNT    | R    | 186A0h | This field indicates the current value of the PWM Low Time Interval Counter. The reset value is the 24'h0186A0. If pwm_en is set to PWM mode, then this register is enabled. This register is reloaded to the PWM low counter_preload value when the error output pin toggles low. It will decrement by 1 each cycle when the error output pin is low. Once the counter has reached 0, the error output pin will toggle high. This field is only reset by a Power-On-Reset (not warm reset). A global soft reset will set this field to 24'h0186A0. |

### 5.5.2.21 ESM\_PWML\_PIN\_CNTR\_PRE Register

#### 1 ESM\_PWML\_PIN\_CNTR\_PRE Register (Offset = 5Ch) [reset = 186A0h]

This register contains the value that is loaded in to the Error PWM Low Counter.

## **5.9.2 GPMC Registers**

### **GPMC Registers**

### 5.9.2.1 GPMC\_REVISION Register

#### 1 GPMC\_REVISION Register (Offset = 0h) [reset = 60h]

This register contains the IP revision code .

### 5.9.2.2 GPMC\_SYSSTATUS Register

#### 1 GPMC\_SYSSTATUS Register (Offset = 14h) [reset = 0h]

This register provides status information about the module, excluding the interrupt status information

### 5.9.2.3 GPMC\_IRQSTATUS Register

#### 1 GPMC\_IRQSTATUS Register (Offset = 18h) [reset = 0h]

This interrupt status register regroups all the status of the module internal events that can generate an interrupt.

### 5.9.2.4 GPMC\_IRQENABLE Register

#### 1 GPMC\_IRQENABLE Register (Offset = 1Ch) [reset = 0h]

The interrupt enable register allows to mask/unmask the module internal sources of interrupt, on a event-by-event basis.

### 5.9.2.7 GPMC\_ERR\_TYPE Register

#### 1 GPMC\_ERR\_TYPE Register (Offset = 48h) [reset = 0h]

The GPMC\_ERR\_TYPE register stores the type of error when an error occurs .

### 5.9.2.18 GPMC\_BCH\_SWDATA Register

#### 1 GPMC\_BCH\_SWDATA Register (Offset = 2D0h) [reset = 0h]

This register is used to directly pass data to the BCH ECC calculator without accessing the actual NAND flash interface.

### 5.9.2.19 GPMC\_CONFIG1 Register

#### 1 GPMC\_CONFIG1 Register (Offset = 60h) [reset = 0h]

The configuration 1 register sets signal control parameters per chip select

Return to [Summary Table](#)

Offset = Base + (j \* 30h); where j = 0 to 3d

**Table 5-1861. I2C\_ICSTR Register Field Descriptions**

| Bit   | Field   | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------|---------|------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:15 | NU2     | NU2  | 0h    | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 14    | SDIR    | R/W  | 0h    | Target Direction. This bit is clear to '0' indicating the I2C is a controller transmitter/receiver or a target receiver. This bit is also clear by STOP condition or START condition. It is set to '1' when the I2C target is a transmitter. In DLB mode [which the configuration should be controller-transmitter target-receiver] this bit is clear to '0'. Writing a "1" to this bit to clear it.                                                                                                                         |
| 13    | NACKSNT | R/W  | 0h    | A No Acknowledge is sent due to NACKMOD is set to a "1".<br>NACKSNT<br>0:A No Acknowledge is not sent. NACKSNT<br>1:A No Acknowledge is sent. Writing a "1" to this bit to clear it.                                                                                                                                                                                                                                                                                                                                         |
| 12    | BB      | R/W  | 0h    | Bus Busy. This bit indicates the state of the serial bus. BB<br>0:The bus is free. BB<br>1:The bus is occupied. On reception of a "start" condition the device sets BB to 1. This bit is also set if the I2C detects SCL low state. BB is clear to 0 after reception of a "stop" condition. BB is kept to "0" regardless SCL state when the I2C is in reset [IRS_ =0]. If the IRS_ is set to "1" during transaction between other I2C devices the BB bit is set at the first falling edge of SCL or START condition. - [RW ] |

**Table 5-1861. I2C\_ICSTR Register Field Descriptions (continued)**

| Bit | Field  | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----|--------|------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 11  | RSFULL | R/W  | 0h    | Receive shift full. This bit indicates whether the receiver has experienced overrun. Overrun occurs when the receive shift register [ICRSR] is full and ICDRR has not been read since the ICRSR-to-ICDRR transfer. The FSM is holding for ICDRR read access. RSFULL is clear when Reading the ICDRR. RSFULL is set to "1" when the I2C has recognized an overrun. The contents of ICDRR are NOT lost in this case. In repeat mode since double buffer [ICRSR and ICDRR] behaves like a single buffer RSFULL is set to "1" every time the data is received. RSFULL is clear as a result of Reading the ICDRR. - [RW ]                                                                                                                 |
| 10  | XSMT   | R/W  | 0h    | Transmit shift empty not. This bit indicates whether the transmitter has experienced underflow. Underflow occurs when the transmit shift register [ICXSR] is empty and ICDXR has not been loaded. The FSM is holding for ICDXR write access. XSMT_ is cleared when underflow has occurred. XSMT_ is set to "1" as a result of Writing to ICDXR. In repeat mode if the I2C in controller transmitter mode is holding transfer with XSMT_ =0 [i.e. waiting for further action] and the STT or STP bit is set XSMT_ is set to "1" by hardware.                                                                                                                                                                                          |
| 9   | AAS    | R/W  | 0h    | Address As Target. This bit is set to 1 by the device when it has recognized its own target address or an address of all [8] zeros. The AAS bit is reset by stop condition or detection of any address byte that does not match ICOAR. - [RW ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 8   | AD0    | R/W  | 0h    | Address Zero Status: This bit is set to 1 by device if it detects the address of all [8] zeros [i.e. general call]. The AD0 bit is reset to 0 [default value] when a "start" or "stop" condition is detected. - [RW ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 7:6 | NU1    | NU1  | 0h    | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 5   | SCD    | R/W  | 0h    | Stop Condition Detection bit SCD is set when the I2C sends or receives STOP condition. This bit is cleared by Reading ICIVR [as 110] or Writing '1' to itself.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 4   | ICXRDY | R/W  | 0h    | Transmit Data Ready interrupt flag bit. ICXRDY is set to "1" is generated when the transmitted data has been copied from ICDXR to the transmit-shift register [ICXSR]. ICXRDY is clear to "0" when the ICDXR is written. This bit can also be polled by the CPU to write a new transmitted data into the ICDXR. Write '1' to this bit will set it and DXR Write will clear it.                                                                                                                                                                                                                                                                                                                                                       |
| 3   | ICRRDY | R/W  | 0h    | Receive Data Ready interrupt flag bit. ICRRDY is set to "1" when the received data has been copied from ICRSR into the ICDRR. ICRRDY is cleared to "0" when the ICDRR is read. This bit can also be polled by the CPU to read the received data in the ICDRR. Write '1' or DRR Read will clear it.                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 2   | ARDY   | R/W  | 0h    | Register-access-ready interrupt flag bit. ARDY is generated by the hardware if the I2C is in the controller mode when the previously programmed data and command has been performed and status bit has been updated. This flag is used by the CPU to let it knows that the I2C registers are ready to be accessed again. When RM=0 ARDY is set when the internal data count is passed 0 if STP register bit has not been set. When RM=1 ARDY is set at each byte end. If the I2C is in FDF mode[FDF=1] ARDY is set just after Start condition. This bit is automatically cleared by hardware when Writing data to ICDXR in transmit mode Reading data from ICDRR in receive mode or setting STT or STP bit. Write '1' will clear it. |
| 1   | NACK   | R/W  | 0h    | No-Acknowledgement interrupt flag bit. The No Acknowledge flag bit is set when the hardware in "controller" mode detects no acknowledge has been received. This bit is NOT set by no-acknowledgement after Start byte Write '1' or Read the ICIVR [as 010] will clear it.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

**Table 5-1861. I2C\_ICSTR Register Field Descriptions (continued)**

| Bit | Field | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----|-------|------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | AL    | R/W  | 0h    | Arbitration-Lost interrupt flag bit. The Arbitration Lost flag bit is set to 1 when the device in the "controller" mode senses it has lost an arbitration when two or more transmitters start a transmission almost simultaneously or when the I2C attempts to start a transfer while BB [bus busy] is 1. When this is set to 1 due to arbitration lost the MST/STT/STP bits are clear the I2C becomes a target. Write '1' or Read the ICIVR [as 001] will clear it. |

### 5.10.2.4 I2C\_ICCLKL Register

#### 1 I2C\_ICCLKL Register (Offset = Ch) [reset = 0h]

I2C Clock Divider Low register

| 15    | NACKMOD | R/W  | 0h    | No Acknowledge [NACK] mode. This bit is used to send an Acknowledge [ACK] or a No Acknowledge [NACK] to the transmitter. This bit is only applicable when the I2C is in receiver mode. In controller receiver mode when the internal data count counter decrements to zero the I2C sends a NACK. The controller receiver I2C finishes a transfer when it sends a NACK. The I2C ignores ICCNT when NACKMOD is '1'. The NACKMOD bit should be set before the rising edge of the last data bit [bit 8] if a NACK must be sent and this bit is cleared once a NACK has been sent. NACKMOD=0 the I2C sends an ACK to the transmitter during the acknowledge cycle. NACKMOD=1 the I2C sends a NACK to the transmitter during the acknowledge cycle. |
| 14    | FREE    | R/W  | 0h    | Free Running. This bit is used to determine the state of the I2C when a breakpoint is encountered in the HLL debugger. FREE 0:[default] Stops immediately if SCL is low and keep driving SCL low whether I2C is controller transmitter/receiver. If SCL is high I2C waits until SCL becomes low and then stops. If the I2C is a target it will stop when the transmission/receiving completes. FREE 1:The I2C runs free.                                                                                                                                                                                                                                                                                                                      |

**Table 5-1882. I2C\_ICMDR Register Field Descriptions (continued)**

| Bit | Field | Type                     | Reset           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                                                                                                                                                                                                                                                                                                                    |     |            |                 |   |   |                   |       |   |                      |      |   |                       |   |                       |                          |   |   |                  |               |

TRX<br>1:The I 2 C is in the"transmitter" mode and the data in ICDXR is shifted out on data line SDA. The operating modes [not in FDF mode] are defined as follows. In FDF mode TRX must be configured even if the I2C is in target mode because there is no address/ direction byte in FDF mode.                                                                                                                                                                                                                                                                                                                                                                            | <table><tr><th>MST</th><th>TRX</th><th>Operating Modes</th></tr><tr><td>0</td><td>x</td><td>"target receiver"</td></tr><tr><td>0</td><td>x</td><td>"target transmitter"</td></tr><tr><td>1</td><td>0</td><td>"controller receiver"</td></tr><tr><td>1</td><td>1</td><td>"controller transmitter"</td></tr></table> | MST | TRX        | Operating Modes | 0 | x | "target receiver" | 0     | x | "target transmitter" | 1    | 0 | "controller receiver" | 1 | 1                     | "controller transmitter" |   |   |                  |               |

| 2:0                     | INTCODE                         | R/W  | 0h    | <p>Interrupt code. The binary-coded-interrupt vector indicates which interrupt has occurred. Reading the ICIVR clears the interrupt code except ARDY[011] RRDY[100] and XRDY[101]. Interrupt code for ARDY RRDY and XRDY is cleared when ARDY ICRRDY and ICXRDY bits in the ICSTR is cleared to default value respectively. If other interrupts are pending a new interrupt is generated. If there are more than one interrupt flag Reading the ICIVR clears the highest priority interrupt code. Reading the ICIVR also clears corresponding status bit in the ICSTR except ARDY ICRRDY ICXRDY and AAS. Note that users must read [clear] the ICIVR before doing another start otherwise the ICIVR could contain incorrect [old interrupt flags] value.</p> <table><tr><td>Interrupt Code</td><td>Interrupt Occurred</td></tr><tr><td>_000_[default]</td><td>None</td></tr><tr><td>_001_[highest priority]</td><td>Arbitration Lost interrupt</td></tr><tr><td>_010</td><td>No Acknowledgement interrupt</td></tr><tr><td>_011</td><td>Register Access Ready interrupt</td></tr><tr><td>_100</td><td>Receive Data Ready interrupt</td></tr><tr><td>_101</td><td>Transmit Data Ready interrupt</td></tr><tr><td>_110</td><td>Stop Condition Detection</td></tr><tr><td>_111_[lowest priority]</td><td>Address As Target - [RW]</td></tr></table> | Interrupt Code | Interrupt Occurred | _000_[default] | None | _001_[highest priority] | Arbitration Lost interrupt | _010 | No Acknowledgement interrupt | _011 | Register Access Ready interrupt | _100 | Receive Data Ready interrupt | _101 | Transmit Data Ready interrupt | _110 | Stop Condition Detection | _111_[lowest priority] | Address As Target - [RW] |

| Bit  | Field  | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------|--------|------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:1 | NU     | R/W  | 0h    | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 0    | PFUNC0 | R/W  | 0h    | Controls the function of the I2C SCL and SDA pins. 0 = Pins function as SCL and SDA 1 = Pins functions as GPIO Note: No hardware protection is required to disable I2C function when the PFUNC[0] and IRS_ bits are both set to one. When PFUNC[0] is "1" [GPIO mode] the sub-module which controls the I2C function receives the value "1" for SCL and SDA. IRS_ can be set to "1" regardless of PFUNC[0] and the I2C function works whenever the IRS_ bit is "1". The user is expected to hold I2C in reset via IRS_ bit when changing to/from GPIO mode via the PFUNC[0] bit. |

### **5.11.2 LIN Registers**

#### **LIN Registers**

### 5.11.2.1 LIN\_SCIGCR0 Register

#### 1 LIN\_SCIGCR0 Register (Offset = 0h) [reset = 0h]

The SCIGCR0 register defines the module reset.

### 5.11.2.2 LIN\_SCIGCR1 Register

#### 1 LIN\_SCIGCR1 Register (Offset = 4h) [reset = 0h]

The SCIGCR1 register defines the frame format, protocol, and communication mode used by the SCI.

| Bit   | Field        | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------|--------------|------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 24    | RXENA        | R/W  | 0h    | <p>Receive enable.</p> <p>This bit is effective in LIN or SCI-compatible mode. RXENA allows or prevents the transfer of data from SCIRXSHF to SCIRD or the receive multibuffers.</p> <p>Note: Clearing RXENA stops received characters from being transferred into the receive buffer or multi-buffers, prevents the RX status flags [see Table 7] from being updated by receive data, and inhibits both receive and error interrupts. However, the shift register continues to assemble data regardless of the state of RXENA.</p> <p>Note: If RXENA is cleared before the time the reception of a frame is complete, the data from the frame is not transferred into the receive buffer.</p> <p>Note: If RXENA is set before the time the reception of a frame is complete, the data from the frame is transferred into the receive buffer. If RXENA is set while SCIRXSHF is in the process of assembling a frame, the status flags are not guaranteed to be accurate for that frame. To ensure that the status flags correctly reflect what was detected on the bus during a particular frame, RXENA should be set before the detection of that frame</p> <p>0 Prevents the receiver from transferring data from the shift buffer to the receive buffer or multi-buffers</p> <p>1 Allows the receiver to transfer data from the shift buffer to the receive buffer or multi-buffers</p> |

| Bit | Field    | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----|----------|------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 12  | HGENCTRL | R/W  | 0h    | <p>HGEN control bit.</p> <p>This bit is effective in LIN mode only. This bit controls the type of mask filtering comparison.</p> <p>0 ID filtering using ID-Byte.</p> <p>RECEIVEDID and IDBYTE fields in the LINID register are used for detecting a match (using TX/RXMASK values). Mask of 0xFF in LINMASK register will result in NO match.</p> <p>1 ID filtering using ID-SlaveTask byte (Recommended).</p> <p>RECEIVEDID and IDSLAVETASKBYTE fields in the LINID register are used for detecting a match (using TX/RXMASK values). Mask of 0xFF in LINMASK register will result in ALWAYS match</p>                                                                                                                                                                                                                                                                                            |
| 11  | CTYPE    | R/W  | 0h    | <p>Checksum type.</p> <p>This bit is effective in LIN mode only. This bit controls the type of checksum to be used: classic or enhanced.</p> <p>0 Classic checksum is used.</p> <p>This checksum is compatible with LIN 1.3 slave nodes. The classic checksum contains the modulo-256 sum with carry over all data bytes. Frames sent with Identifier 60 (0x3C) to 63 (0x3F) must always use the classic checksum.</p> <p>1 Enhanced checksum is used.</p> <p>The enhanced checksum is compatible with LIN 2.0 and newer slave nodes. The enhanced checksum contains the modulo-256 sum with carry over all data bytes AND the protected Identifier.</p>                                                                                                                                                                                                                                            |
| 10  | MBUFMODE | R/W  | 0h    | <p>Multibuffer mode.</p> <p>This bit is effective in LIN or SCI-compatible mode. This bit controls receive/transmit buffer usage, that is, whether the RX/TX multibuffers are used or a single register, RD0/TD0, is used.</p> <p>0 The multi-buffer mode is disabled.</p> <p>1 The multi-buffer mode is enabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 9   | ADAPT    | R/W  | 0h    | <p>Adapt mode enable.</p> <p>This mode is effective in LIN mode only. This bit has an effect during the detection of the Sync Field. There are two LIN protocol bit rate modes that could be enabled with this bit according to the Node capability file definition: automatic or select. Software and network configuration will decide which of the previous two modes. When this bit is cleared, the LIN 2.0 protocol fixed bit rate should be used. If the ADAPT bit is set, a LIN slave node detecting the baudrate will compare it to the prescalers in BRSR register and update it if they are different. The BRSR register will be updated with the new value. If this bit is not set there will be no adjustment to the BRSR register. This field is writable in LIN mode only.</p> <p>0 Automatic baudrate adjustment is disabled.</p> <p>1 Automatic baudrate adjustment is enabled.</p> |

**Table 5-1929. LIN\_SCIGCR1 Register Field Descriptions (continued)**

| Bit | Field      | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----|------------|------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 8   | SLEEP      | R/W  | 0h    | <p>SCI sleep.</p> <p>SCI compatibility mode only. In a multiprocessor configuration, this bit controls the receive sleep function. Clearing this bit brings the SCI out of sleep mode.</p> <p>The receiver still operates when the SLEEP bit is set; however, RXRDY is updated and SCIRD is loaded with new data only when an address frame is detected. The remaining receiver status flags are updated and an error interrupt is requested if the corresponding interrupt enable bit is set, regardless of the value of the SLEEP bit. In this way, if an error is detected on the receive data line while the SCI is asleep, software can promptly deal with the error condition. The SLEEP bit is not automatically cleared when an address byte is detected.</p> <p>This field is writable in SCI mode only.</p> <p>0 Sleep mode is disabled.<br/>1 Sleep mode is enabled.</p> |
| 7   | SWNRST     | R/W  | 0h    | <p>Software reset [active low].</p> <p>This bit is effective in LIN or SCI-compatible mode. The SCI/LIN should only be configured while SWnRST = 0.</p> <p>Only the following configuration bits can be changed in runtime [i.e., while SWnRESET = 1]:</p> <ul style="list-style-type: none"> <li>- STOP EXT Frame [SCIGCR1[13]]</li> <li>- CC bit [SCIGCR2[17]]</li> <li>- SC bit [SCIGCR2[16]]</li> </ul> <p>0 The SCI/LIN is in its reset state; no data will be transmitted or received. Writing a 0 to this bit initializes the SCI/LIN state machines and operating flags. All affected logic is held in the reset state until a 1 is written to this bit.</p> <p>1 The SCI/LIN is in its ready state; transmission and reception can occur. After this bit is set to 1, the configuration of the module should not change.</p>                                               |
| 6   | LINMODE    | R/W  | 0h    | <p>LIN mode</p> <p>This bit controls the mode of operation of the module.</p> <p>0 LIN mode is disabled; SCI compatibility mode is enabled.<br/>1 LIN mode is enabled; SCI compatibility mode is disabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 5   | CLK_MASTER | R/W  | 0h    | <p>SCI internal clock enable or LIN Master/Slave configuration.</p> <p>In the SCI mode, this bit enables the clock to the SCI module. In LIN mode, this bit determines whether a LIN node is a slave or master.</p> <p>0 SCI-compatible mode: Reserved.<br/>LIN mode: The module is in slave mode.<br/>1 SCI-compatible mode: Enable clock to the SCI module.<br/>LIN mode: The node is in master mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 4   | STOP       | R/W  | 0h    | <p>SCI number of stop bits.</p> <p>This bit is effective in SCI-compatible mode only.</p> <p>Note: The receiver checks for only one stop bit. However in idle-line mode, the receiver waits until the end of the second stop bit [if STOP = 1] to begin checking for an idle period.</p> <p>This field is writable in SCI mode only.</p> <p>0 One stop bit is used.<br/>1 Two stop bits are used.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

**Table 5-1929. LIN\_SCIGCR1 Register Field Descriptions (continued)**

| Bit | Field      | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----|------------|------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3   | PARITY     | R/W  | 0h    | <p>SCI parity odd/even selection.</p> <p>This bit is effective in SCI-compatible mode only. If the PARITY ENA bit [SCIGCR1.2] is set, PARITY designates odd or even parity. The parity bit is calculated based on the data bits in each frame and the address bit [in address-bit mode]. The start and stop fields in the frame are not included in the parity calculation.</p> <p>This field is writable in SCI mode only.</p> <p>0      Odd parity is used. The SCI transmits and expects to receive a value in the parity bit that makes odd the total number of bits in the frame with the value of 1.</p> <p>1      Even parity is used. The SCI transmits and expects to receive a value in the parity bit that makes even the total number of bits in the frame with the value of 1.</p> |
| 2   | PARITYENA  | R/W  | 0h    | <p>Parity enable.</p> <p>Enables or disables the parity function.</p> <p>0      SCI-compatible mode: Parity disabled; no parity bit is generated during transmission or is expected during reception.</p> <p>LIN mode: ID-parity verification is disabled.</p> <p>1      SCI compatible mode: Parity enabled. A parity bit is generated during transmission and is expected during reception.</p> <p>LIN mode: ID-parity verification is enabled.</p>                                                                                                                                                                                                                                                                                                                                           |

### 5.11.2.3 LIN\_SCIGCR2 Register

#### 1 LIN\_SCIGCR2 Register (Offset = 8h) [reset = 0h]

The SCIGCR2 register is used to send or compare a checksum byte during extended frames, to generate a wakeup and for low-power mode control of the LIN module.

| 0    | POWERDOWN  | R/W  | 0h    | <p>Power down.</p> <p>This bit is effective in LIN or SCI-compatible mode. When the powerdown bit is set, the SCI/LIN module attempts to enter local low-power mode. If the POWERDOWN bit is set while the receiver is actively receiving data and the wakeup interrupt is disabled, then the SCI/LIN will delay low-power mode from being entered until completion of reception. In LIN mode the user may set the POWERDOWN bit on Sleep Command reception or on idle bus detection [more than 4 seconds, i.e. 80,000 cycles at 20kHz]</p> <p>0 Normal operation<br/>1 Request local low-power mode</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

### 5.11.2.4 LIN\_SCISSETINT Register

#### 1 LIN\_SCISSETINT Register (Offset = Ch) [reset = 0h]

The SCISSETINT register is used to enable the various interrupts available in the LIN module.

| 1   | SETWAKEUPINT  | R/W1TS | 0h    | <p>Set wake-up interrupt.</p> <p>This bit is effective in LIN or SCI-compatible mode. Setting this bit enables the SCI/LIN to generate a wake-up interrupt and thereby exit low-power mode. The wake-up interrupt is asserted on falling edge of the wake-up pulse. If enabled, the wake-up interrupt is asserted when local low-power mode is requested while the receiver is busy or if a low level is detected on the SCIRX pin during low-power mode. Wake-up interrupt is not asserted upon a wakeup pulse if the module is not in power down mode.</p> <p>0        Interrupt is disabled. Writing a 0 to this bit has no effect.</p> <p>1        Interrupt is enabled.</p> |
| 0   | SETBRKDTINT   | R/W1TS | 0h    | <p>Set break-detect interrupt.</p> <p>This bit is effective in SCI-compatible mode only. Setting this bit enables the SCI/LIN to generate an interrupt if a break condition is detected on the LINRX pin.</p> <p>This field is writable in SCI mode only.</p> <p>0        Interrupt is disabled. Writing a 0 to this bit has no effect.</p> <p>1        Interrupt is enabled.</p>                                                                                                                                                                                                                                                                                                |

### 5.11.2.5 LIN\_SCICLEARINT Register

#### 1 LIN\_SCICLEARINT Register (Offset = 10h) [reset = 0h]

The SCICLEARINT register is used to disable the enabled interrupts without accessing the SCISSETINT register.

### 5.11.2.6 LIN\_SCISSETINTLVL Register

#### 1 LIN\_SCISSETINTLVL Register (Offset = 14h) [reset = 0h]

The SCISSETINTLVL register is used to map individual interrupt sources to the INT1 interrupt line.

Return to [Summary Table](#)

**Table 5-1939. Instance Table**

| Instance Name | Physical Address |
|---------------|------------------|
| LIN0          | 5240 0014h       |

### 5.11.2.7 LIN\_SCICLEARINTLVL Register

#### 1 LIN\_SCICLEARINTLVL Register (Offset = 18h) [reset = 0h]

The SCICLEARINTLVL register is used to map individual interrupt sources to the INT0 line.

Return to [Summary Table](#)

### 5.11.2.8 LIN\_SCIFLR Register

#### 1 LIN\_SCIFLR Register (Offset = 1Ch) [reset = 904h]

The SCIFLR register indicates the current status of the various interrupt sources of the LIN module.

Return to [Summary Table](#)

**Table 5-1945. Instance Table**

| Instance Name | Physical Address |
|---------------|------------------|
| LIN0          | 5240 001Ch       |
| LIN1          | 5240 101Ch       |
| LIN2          | 5240 201Ch       |
| LIN3          | 5240 301Ch       |
| LIN4          | 5240 401Ch       |

| Bit | Field | Type   | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----|-------|--------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 30  | PBE   | R/W1TC | 0h    | <p>Physical Bus Error Flag.</p> <p>This bit is effective in LIN mode only. This bit is set when there has been a physical bus error. This is detected by the bit monitor in TED. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- Setting the SWnRESET bit [SCIGCR1.7]</li> <li>- RESET bit [SCIGCR0.0]</li> <li>- System reset</li> <li>- Writing a 1 to this bit</li> <li>- Reception of a new sync break</li> </ul> <p>Note: this PBE will only be flagged if no sync break can be generated. [because of a bus shortage to VBAT] or if no sync break delimiter can be generated [because of a bus shortage to GND]. This field is writable in LIN mode only.</p> <p>0 No physical bus error detected.<br/>1 Physical bus error detected.</p> |
| 29  | CE    | R/W1TC | 0h    | <p>Checksum Error Flag.</p> <p>This bit is effective in LIN mode only. This bit is set when there is checksum error detected by a receiving node. The type of checksum to be used depends on the SCIGCR1.CTYPE bit. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- Setting the SWnRESET bit [SCIGCR1.7]</li> <li>- RESET bit [SCIGCR0.0]</li> <li>- System reset</li> <li>- Writing a 1 to this bit</li> <li>- Reception of a new sync break</li> </ul> <p>This field is writable in LIN mode only.</p> <p>0 No Checksum error detected.<br/>1 Checksum error detected.</p>                                                                                                                                                                    |
| 28  | ISFE  | R/W1TC | 0h    | <p>Inconsistent Sync Field Error Flag.</p> <p>This bit is effective in LIN mode only. This bit is set when there has been an inconsistent Sync Field error detected by the synchronizer during header reception. See the "Header Reception and Adaptive Baudrate" section for more information. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- Setting the SWnRESET bit [SCIGCR1.7]</li> <li>- RESET bit [SCIGCR0.0]</li> <li>- System reset</li> <li>- Writing a 1 to this bit</li> <li>- Reception of a new sync break</li> </ul> <p>This field is writable in LIN mode only.</p> <p>0 No Inconsistent Sync Field error detected.<br/>1 Inconsistent Sync Field error detected.</p>                                                          |

**Table 5-1947. LIN\_SCIFLR Register Field Descriptions (continued)**

| Bit | Field | Type   | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----|-------|--------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 27  | NRE   | R/W1TC | 0h    | <p>No-Response Error Flag.</p> <p>This bit is effective in LIN mode only. This bit is set when there is no response to a master's header completed within TFRAME_MAX. This timeout period is applied for message frames of unknown length [identifiers 0 to 61]. This error is detected by the synchronizer of the module. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- Setting the SWnRESET bit [SCIGCR1.7]</li> <li>- RESET bit [SCIGCR0.0]</li> <li>- System reset</li> <li>- Writing a 1 to this bit</li> <li>- Reception of a new sync break</li> </ul> <p>This field is writable in LIN mode only.</p> <p>0 No No-Response error detected.<br/>1 No-Response error detected.</p>                                                                                                                                                                                         |
| 26  | FE    | R/W1TC | 0h    | <p>Framing error flag.</p> <p>This bit is effective in LIN or SCI-compatible mode. This bit is set when an expected stop bit is not found. In SCI compatible mode, only the first stop bit is checked. The missing stop bit indicates that synchronization with the start bit has been lost and that the character is incorrectly framed. Detection of a framing error causes the SCI to generate an error interrupt if the RXERR INT ENA bit is set. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- Setting the SWnRESET bit [SCIGCR1.7]</li> <li>- RESET bit [SCIGCR0.0]</li> <li>- System reset</li> <li>- Writing a 1 to this bit</li> <li>- Reception of a new character [SCI-compatible mode], or frame [LIN mode]</li> </ul> <p>In multibuffer mode the frame is defined in the SCIFORMAT register.</p> <p>0 No framing error detected.<br/>1 Framing error detected.</p> |
| 25  | OE    | R/W1TC | 0h    | <p>Overrun error flag.</p> <p>This bit is effective in LIN or SCI-compatible mode. This bit is set when the transfer of data from SCIRXSHF to SCIRD overwrites unread data already in SCIRD or the RDy buffers. Detection of an overrun error causes the LIN to generate an error interrupt if the SET OE INT bit is one. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- Setting the SWnRESET bit [SCIGCR1.7]</li> <li>- RESET bit [SCIGCR0.0]</li> <li>- System reset</li> <li>- Writing a 1 to this bit</li> </ul> <p>0 No overrun error detected.<br/>1 Overrun error detected.</p>                                                                                                                                                                                                                                                                                           |

| 24    | PE         | R/W1TC | 0h    | <p>Parity error flag.</p> <p>This bit is effective in LIN or SCI-compatible mode. This bit is set when a parity error is detected in the received data. In SCI address-bit mode, the parity is calculated on the data and address bit fields of the received frame. In idle-line mode, only the data is used to calculate parity. An error is generated when a character is received with a mismatch between the number of 1s and its parity bit. For more information on parity checking, see the "SCI Global Control Register [SCIGCR1]" description. If the parity function is disabled [that is, SCIGCR1.2 = 0], the PE flag is disabled and read as 0. Detection of a parity error causes the LIN to generate an error interrupt if the SET PE INT bit = 1. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- Setting the SWnRESET bit [SCIGCR1.7]</li> <li>- RESET bit [SCIGCR0.0]</li> <li>- System reset</li> <li>- Reception of a new character [SCI-compatible mode] or frame [LIN mode]</li> <li>- Writing a 1 to this bit</li> </ul> <p>0 No parity error or parity disabled.<br/>1 Parity error detected.</p> |

| Bit | Field  | Type   | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----|--------|--------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 10  | TXWAKE | R/W    | 0h    | <p>SCI transmitter wakeup method select.</p> <p>This bit is effective in SCI-compatible mode only. The TXWAKE bit controls whether the data in SCITD should be sent as an address or data frame using multiprocessor communication format. This bit is set to 1 or 0 by software before a byte is written to SCITD and is cleared by the SCI when data is transferred from SCITD to SCITXSHF or by a system reset. TXWAKE is not cleared by the SWnRESET bit [SCIGCR1.7].</p> <p>0 Address-bit mode: Frame to be transmitted will be data (address bit = 0).</p> <p>Idle-line mode: Frame to be transmitted will be data.</p> <p>1 Address-bit mode: Frame to be transmitted will be an address (address bit=1).</p> <p>Idle-line mode: Following frame to be transmitted will be an address (writing a 1 to this bit followed by writing dummy data to the SCITD will result in a idle period of 11 bit periods before the next frame is transmitted).</p>                                                                                                                                                          |
| 9   | RXRDY  | R/W1TC | 0h    | <p>Receiver ready flag.</p> <p>In SCI compatibility mode, the receiver sets this bit to indicate that the SCIRD contains new data and is ready to be read by the CPU. In LIN mode, RXRDY is set once a valid frame is received in multibuffer mode, a valid frame being a message frame received with no errors. In non multibuffer mode RXRDY is set for each received byte and will be set for the last byte of the frame if there are no errors. The SCI/LIN generates a receive interrupt when RXRDY flag bit is set if the interrupt-enable bit is set [SCISSETINT.9]. RXRDY is cleared by:</p> <ul style="list-style-type: none"> <li>- RESET bit [SCIGCR0.0]</li> <li>- Setting the SWnRESET</li> <li>- System reset</li> <li>- Writing a 1 to this bit</li> <li>- Reading SCIRD in while in SCI compatibility mode</li> <li>- Reading last data byte RDy of the response in LIN mode</li> </ul> <p>Note: The RXRDY flag cannot be cleared by Reading the corresponding interrupt offset in the SCIINTVECT0/1 register.</p> <p>0 No new data in SCIRD/RDy.</p> <p>1 New data ready to be read from SCIRD.</p> |

**Table 5-1947. LIN\_SCIFLR Register Field Descriptions (continued)**

| Bit | Field      | Type   | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----|------------|--------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 8   | TXRDY      | R      | 1h    | <p>Transmitter buffer register ready flag.</p> <p>When set, this bit indicates that the transmit buffer[s] register [SCITD in compatibility mode and LINTD0, LINTD1 in MBUF mode] is/are ready to get another character from a CPU write.</p> <p>In SCI compatibility mode, Writing data to SCITD automatically clears this bit. In LIN mode, this bit is cleared once byte 0 [TD0] is written to LINTD0. This bit is set after the data of the TX buffer are shifted into the SCITXSHF register. This event can trigger a transmit DMA event if the DMA enable bit is set. This bit is set to 1 by:</p> <ul style="list-style-type: none"> <li>- RESET bit [SCIGCR0.0]</li> <li>- Setting the SWnRESET [SCIGCR1.7]</li> <li>- System reset</li> </ul> <p>Note: The TXRDY flag cannot be cleared by Reading the corresponding interrupt offset in the SCIINTVECT0/1 register.</p> <p>Note: The transmit interrupt request can be eliminated until the next series of data is written into the transmit buffers LINTD0 and LINTD1, by disaLINg the corresponding interrupt via the SCICLEARINT register or by disaLINg the transmitter via the TXENA bit [SCIGCR1.25=0].</p> <p>0      Compatible mode: SCITD is full.<br/>LIN<br/>mode: The multibuffers are full.</p> <p>1      Compatible mode: SCITD is ready to receive the next character.<br/>LIN mode: The multibuffers are ready to receive the next character(s).</p> |
| 7   | TOA3WUS    | R/W1TC | 0h    | <p>Timeout After 3 Wakeup Signals flag.</p> <p>This bit is effective in LIN mode only. This flag is set if there is no Sync Break received after 3 wakeup signals and a period of 1.5 seconds have passed. Such expiration time is used before issuing another round of wakeup signals. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- Setting the SWnRESET bit [SCIGCR1.7]</li> <li>- RESET bit [SCIGCR0.0]</li> <li>- System reset</li> <li>- Writing a 1 to this bit</li> </ul> <p>This field is writable in LIN mode only.</p> <p>0      No timeout after 3 wakeup signals.<br/>1      Timeout after 3 wakeup signals and 1.5s time.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 6   | TOAWUS     | R/W1TC | 0h    | <p>Timeout After Wakeup Signal flag.</p> <p>This bit is effective in LIN mode only. This bit is set if there is no Sync Break received after a wakeup signal has been sent. A minimum of 150 ms expiration time is used before issuing another wakeup signal. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- Setting the SWnRESET bit [SCIGCR1.7]</li> <li>- RESET bit [SCIGCR0.0]</li> <li>- System reset</li> <li>- Writing a 1 to this bit</li> </ul> <p>This field is writable in LIN mode only.</p> <p>0      No timeout after one wakeup signal (150 ms).<br/>1      Timeout after one wakeup signal.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

**Table 5-1947. LIN\_SCIFLR Register Field Descriptions (continued)**

| Bit | Field   | Type   | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----|---------|--------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4   | TIMEOUT | R/W1TC | 0h    | <p>LIN Bus IDLE timeout flag.</p> <p>This bit is effective in LIN mode only. This bit is set if there is no LIN bus activity for at least 4 seconds. LIN bus activity being a transition from recessive to dominant. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- Setting the SWnRESET bit [SCIGCR1.7]</li> <li>- RESET bit [SCIGCR0.0]</li> <li>- System reset</li> <li>- Writing a 1 to this bit</li> </ul> <p>This field is writable in LIN mode only.</p> <p>0 No bus idle detected.<br/>1 LIN bus idle detected.</p>                                                                                                                                                                                                                       |
| 3   | BUSY    | R      | 0h    | <p>Bus BUSY flag.</p> <p>This bit is effective in LIN mode and SCI-compatible mode. This bit indicates whether the receiver is in the process of receiving a frame. As soon as the receiver detects the beginning of a start bit, the BUSY bit is set to 1. When the reception of a frame is complete, the BUSY bit is cleared. If SET WAKEUP INT is set and power down is requested while this bit is set, the SCI/LIN automatically prevents low-power mode from being entered and generates wakeup interrupt. The BUSY bit is controlled directly by the SCI receiver but can be cleared by:</p> <ul style="list-style-type: none"> <li>- Setting the SWnRESET bit [SCIGCR1.7]</li> <li>- RESET bit [SCIGCR0.0]</li> <li>- System reset.</li> </ul> <p>0 Receiver is not currently receiving a frame.<br/>1 Receiver is currently receiving a frame.</p> |
| 2   | IDLE    | R      | 1h    | <p>SCI receiver in idle state.</p> <p>This bit is effective in SCI-compatible mode only. While this bit is set, the SCI looks for an idle period to resynchronize itself with the bit stream. The receiver does not receive any data while the bit is set. The bus must be idle for 11 bit periods to clear this bit. The SCI enters this state:</p> <ul style="list-style-type: none"> <li>- After a system reset</li> <li>- Setting the SWnRESET bit [SCIGCR1.7]</li> <li>- After coming out of power down</li> </ul> <p>This bit is writable in SCI mode only.</p> <p>0 Idle period detected, the SCI is ready to receive.<br/>1 Idle period not detected, the SCI will not receive any data.</p>                                                                                                                                                        |
| 1   | WAKEUP  | R/W1TC | 0h    | <p>Wake-up flag.</p> <p>This bit is effective in LIN mode only. This bit is set by the SCI/LIN when receiver or transmitter activity has taken the module out of power-down mode. An interrupt is generated if the SET WAKEUP INT bit [SCISETINT.1] is set. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register.</li> <li>- Setting the SWnRESET bit [SCIGCR1.7]</li> <li>- RESET bit [SCIGCR0.0]</li> <li>- System reset</li> <li>- Writing a 1 to this bit.</li> </ul> <p>This field is writable in LIN mode only.</p> <p>0 Do not wake up from power-down mode.<br/>1 wake up from power-down mode.</p>                                                                                                                                                        |

**Table 5-1947. LIN\_SCIFLR Register Field Descriptions (continued)**

| Bit | Field | Type   | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----|-------|--------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | BRKDT | R/W1TC | 0h    | <p>SCI break-detect flag.</p> <p>This bit is effective in SCI-compatible mode only. This bit is set when the SCI detects a break condition on the LINRX pin. A break condition occurs when the LINRX pin remains continuously low for at least 10 bits after a missing first stop bit, that is, after a framing error. Detection of a break condition causes the SCI to generate an error interrupt if the BRKDT INT ENA bit is set. The BRKDT bit is cleared by the following:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register.</li> <li>- Setting the SWnRESET bit [SCIGCR1.7]</li> <li>- RESET bit [SCIGCR0.0]</li> <li>- System reset</li> <li>- By Writing a 1 to this bit.</li> </ul> <p>This bit is writable in SCI mode only.</p> <p>0        No break condition detected.<br/>1        Break condition detected.</p> |

### 5.11.2.9 LIN\_SCIINTVECT0 Register

#### 1 LIN\_SCIINTVECT0 Register (Offset = 20h) [reset = 0h]

The SCIINTVECT0 register indicates the offset for the INT0 interrupt line.

| 4:0   | INTVECT1   | R    | 0h    | Interrupt vector offset for INT1.<br>This register indicates the offset for interrupt line INT1. A read to this register updates its value to the next highest priority pending interrupt in SCIFLR and clears the flag corresponding to the offset that was read.<br>Note: The flags for the receive [SCIFLR.9] and the transmit [SCIFLR.8] interrupts cannot be cleared by Reading the corresponding offset vector in this register [see detailed description in SCIFLR register]. |

### 5.11.2.11 LIN\_SCIFORMAT Register

#### 1 LIN\_SCIFORMAT Register (Offset = 28h) [reset = 0h]

The SCIFORMAT register is used to set up the character and frame lengths.

### 5.11.2.13 LIN\_SCIED Register

#### 1 LIN\_SCIED Register (Offset = 30h) [reset = 0h]

The SCIED register is a duplicate copy of SCIRD register that has no effect on the RXRDY flag for use with an emulator.

| 7:0  | RD         | R    | 0h    | Received Data.<br>This bit is effective in SCI-compatible mode only. When a frame has been completely received, the data in the frame is transferred from the receiver shift register SCIRXSHF to this register. As this transfer occurs, the RXRDY flag is set and a receive interrupt is generated if RX INT ENA [SCISSETINT0.9] is set. When the data is read from SCIRD, the RXRDY flag is automatically cleared.<br>When the SCI receives data that is fewer than eight bits in length, it loads the data into this register in a left justified format padded with trailing zeros. Therefore, your software should perform a logical shift on the data by the correct number of positions to make it right justified. |

### 5.11.2.15 LIN\_SCITD Register

#### 1 LIN\_SCITD Register (Offset = 38h) [reset = 0h]

The SCITD register is where data to be transmitted is written to by application software.

| 7:0  | TD         | R/W  | 0h    | Transmit data<br>This bit is effective in SCI-compatible mode only. Data to be transmitted is written to this register. The transfer of data from this register to the transmit shift register SCITXSHF sets the TXRDY flag [SCIFLR.23], which indicates that SCITD is ready to be loaded with another byte of data. Note: If TX INT ENA [SCISSETINT.8] is set, this data transfer also causes an interrupt.<br>Note: Data written to the SCIRD register that is fewer than eight bits long must be right justified, but it does not need to be padded with leading zeros. |

### 5.11.2.16 LIN\_SCIPIO0 Register

#### 1 LIN\_SCIPIO0 Register (Offset = 3Ch) [reset = 0h]

The SCIPIO0 register is used to enable the LINTX and LINRX pins.
