Register 18: EPI Read FIFO Count (EPIRFIFOCNT), offset 0x06C

This register returns the number of values in the NBRFIFO (the data in the NBRFIFO can be read via the **EPIREADFIFO** register). A race is possible, but that only means that more values may come in after this register has been read.

EPI Read FIFO Count (EPIRFIFOCNT)

Register 19: EPI Read FIFO (EPIREADFIFO0), offset 0x070

Register 20: EPI Read FIFO Alias 1 (EPIREADFIFO1), offset 0x074

Register 21: EPI Read FIFO Alias 2 (EPIREADFIFO2), offset 0x078

Register 22: EPI Read FIFO Alias 3 (EPIREADFIFO3), offset 0x07C

Register 23: EPI Read FIFO Alias 4 (EPIREADFIFO4), offset 0x080

Register 24: EPI Read FIFO Alias 5 (EPIREADFIFO5), offset 0x084

Register 25: EPI Read FIFO Alias 6 (EPIREADFIFO6), offset 0x088

Register 26: EPI Read FIFO Alias 7 (EPIREADFIFO7), offset 0x08C

Important: This register is read-sensitive. See the register description for details.

This register returns the contents of the NBRFIFO or 0 if the NBRFIFO is empty. Each read returns the data that is at the top of the NBRFIFO, and then empties that value from the NBRFIFO. The alias registers can be used with the LDmia instruction for more efficient operation (for up to 8 registers). See *Cortex™-M3/M4 Instruction Set Technical User's Manual (literature number SPMU159)* for more information on the LDmia instruction.

Register 27: EPI FIFO Level Selects (EPIFIFOLVL), offset 0x200

This register allows selection of the FIFO levels which trigger an interrupt to the interrupt controller or, more efficiently, a DMA request to the μ DMA. The NBRFIFO select triggers on fullness such that it triggers on match or above (more full) in order for the processor or the μ DMA to extract the read data. The WFIFO triggers on emptiness such that it triggers on match or below (less entries) in order for the processor or the μ DMA to insert more write data.

It should be noted that the FIFO triggers are not identical to other such FIFOs in TM4C129XKCZAD peripherals. In particular, empty and full triggers are provided to avoid wait states when using blocking operations.

The settings in this register are only meaningful if the μ DMA is active or the interrupt is enabled.

Additionally, this register allows protection against writes stalling and notification of performing blocking reads which stall for extra time due to preceding writes. The two functions behave in a non-orthogonal way because read and write are not orthogonal.

The write error bit configures the system such that an attempted write to an already full WFIFO abandons the write and signals an error interrupt to prevent accidental latencies due to stalling writes.

The read error bit configures the system such that after a read has been stalled due to any preceding writes in the WFIFO, the error interrupt is generated. Note that the excess stall is not prevented, but an interrupt is generated after the fact to notify that it has happened.

Register 28: EPI Write FIFO Count (EPIWFIFOCNT), offset 0x204

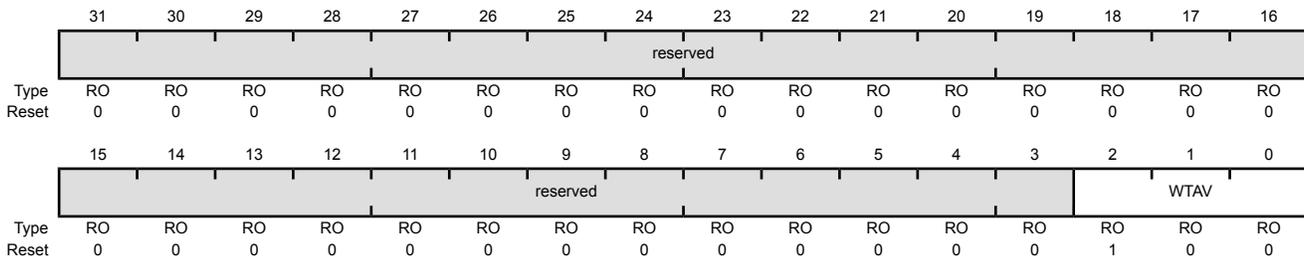

This register contains the number of slots currently available in the WFIFO. This register may be used for polled writes to avoid stalling and for blocking reads to avoid excess stalling (due to undrained writes). An example use for writes may be:

```
for (idx = 0; idx < cnt; idx++) {
while (EPIWFIFOCNT == 0) ;
*ext_ram = *mydata++;
}
```

The above code ensures that writes to the address mapped location do not occur unless the WFIFO has room. Although polling makes the code wait (spinning in the loop), it does not prevent interrupts being serviced due to bus stalling.

EPI Write FIFO Count (EPIWFIFOCNT)

Base 0x400D.0000

| 2:0 | WTAV | RO | 0x4 | Available Write Transactions The number of write transactions available in the WFIFO. When clear, a write is stalled waiting for a slot to become free (from a preceding write completing). |

Register 29: EPI DMA Transmit Count (EPIDMATXCNT), offset 0x208

This register is used to program the total number of transfers (byte, halfword or word) by the μ DMA to WRFIFO. As each transfer is processed by the EPI, the TXCNT bit field value is decreased by 1. When TXCNT = 0, the EPI's uDMA request signal is deasserted.

Register 31: EPI Raw Interrupt Status (EPIRIS), offset 0x214

This register is the raw interrupt status register. On a read, it gives the current state of each interrupt source. A write has no effect.

Note that raw status for read and write is set or cleared based on FIFO fullness as controlled by **EPIFIFOLVL**.

Raw status for error is held until the error is cleared by writing to the **EPIEISC** register.

Register 32: EPI Masked Interrupt Status (EPIMIS), offset 0x218

This register is the masked interrupt status register. On read, it gives the current state of each interrupt source (read, write, and error) after being masked via the **EPIIM** register. A write has no effect.

The values returned are the ANDing of the **EPIIM** and **EPIRIS** registers. If a bit is set in this register, the interrupt is sent to the interrupt controller.

Register 33: EPI Error and Interrupt Status and Clear (EPIEISC), offset 0x21C

This register is used to clear a pending error interrupt. Clearing any defined bit in the **EPIEISC** has no effect; setting a bit clears the error source and the raw error returns to 0. When any of bits[2:0] of this register are read as set, it indicates that the **ERRRIS** bit in the **EPIRIS** register is set and an EPI controller error is sent to the interrupt controller if the **ERIM** bit in the **EPIIM** register is set. If any of bits [2:0] are written as 1, the register bit being written to, as well as the **ERRRIS** bit in the **EPIRIS** register and the **ERIM** bit in the **EPIIM** register are cleared. If the **DMAWRIC** or **DMARDIC** bit in this register is set, then the corresponding bit in the **EPIRIS** and **EPIMIS** register is cleared. Note that writing to this register and reading back immediately (pipelined by the processor) returns the old register contents. One cycle is needed between write and read.

Register 46: EPI Host-Bus PSRAM (EPIHBPSRAM), offset 0x360

This register holds the PSRAM configuration register value. When the `WRCRE` bit in the `EPIHB16CFGn` register is set, all 21 bits of the `EPIHBPSRAM` register's `CR` value are written to the PSRAM's configuration register. When the `RDCRE` bit is set in the `EPIHB16CFGn` register, a read of the PSRAM's configuration register takes place and the value is written to bits[15:0] of the `EPIHBPSRAM`. Bits[20:16] will not contain any valid data.

EPI Host-Bus PSRAM (EPIHBPSRAM)

Base 0x400D.0000
 Offset 0x360
 Type RW, reset 0x0000.0000

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|----------|---|
| 31:21 | reserved | RO | 0x000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 20:0 | CR | RW | 0x000000 | PSRAM Config Register During a configuration write, all 21 bits of the <code>CR</code> bit field are written to the PSRAM. During configuration reads, <code>CR</code> bits[15:0] of this register contain the configuration read of the PSRAM. <code>CR</code> [20:16] will not contain valid data. |

12 Cyclical Redundancy Check (CRC)

The Cyclical Redundancy Check (CRC) computation module can be used for message transfer and safety system checks, as well as in conjunction with the AES and DES modules. The following features are supported:

- Support four major CRC forms:
 - CRC16-CCITT as used by CCITT/ITU X.25
 - CRC16-IBM as used by USB and ANSI
 - CRC32-IEEE as used by IEEE802.3 and MPEG2
 - CRC32C as used by G.Hn
- Allows word and byte feed
- Supports auto-initialization and manual initialization
- Supports MSb and LSb
- Supports CCITT post-processing
- Can be fed by μ DMA, Flash memory and code

12.1 Functional Description

The following sections describe the features of CRC.

12.1.1 CRC Support

The purpose of the CRC engine is to accelerate CRC and TCP checksum operation. The result of the CRC operation is a 32- and 16-bit signature which can be used to check the sanity of data. The required mode of operation is selected through the `TYPE` bit in the **CRC Control (CRCCTRL)** register, offset 0x400. A μ DMA software channel can be used to burst data into the CRC module. CRCs are computed combinatorially in one clock.

The CRC module contains all of the control registers to which the input context interfaces. Because CRC calculations are a single cycle, as soon as data is written to **CRC Data Input (CRCDIN)** register, the result of CRC/CSUM is updated in the **CRC SEED/Context (CRCSEED)** register, offset 0x410. The input data is computed by the selected CRC polynomial or CSUM.

12.1.1.1 CRC Checksum engine

Software can offload the CRC and checksum task to the CRC checksum engine accelerator. The accelerator has registers that need to be programmed to initiate processing. These registers should be fed with data in order to calculate CRC/CSUM. Software should configure the μ DMA channel for data movement through the **DMA Channel Map Select n (DMACHMAPn)** register in the μ DMA module. Further μ DMA configuration guidelines are available in the “Micro Direct Memory Access (μ DMA)” on page 708.

The starting seed for the CRC and checksum operation is programmed in the **CRC SEED/Context (CRCSEED)** register at offset 0x410. Depending on the encoding of the `INIT` field in the **CRCCTRL** register, the value of the `SEED` field can be initialized to any one of the following:

- A unique context value written to the **CRCSEED** register (`INIT=0x0`)
- All 0s (`INIT=0x2`)
- All 1s (`INIT=0x3`)

Once the operation is done, software should read the result from the **CRC Post Processing Result (CRCRSLTPP)** register, offset 0x418, and a software channel μ DMA interrupt should be used to identify completion.

12.1.1.2 Data Size

The CRC module supports data being fed 32-bit words and 8 bits at a time and can dynamically switch back and forth. The data size is configured by programming the `SIZE` bit in the **CRCCTRL** register, offset 0x400.

Because CRC is a division on a long stream of bits, the application must take into consideration the bit order. When processing message data that is read out by words, bit order is not an issue. For example, if the data value in the message is 0x12345678, the most significant eight byte is 0x12 (00010010 in binary). If the data is processed as bytes, 0x12, 0x34, 0x56, and 0x78 are copied into memory in that order and the word is stored as 0x78563412, where 0x12 is written as byte 0, 0x34 is written as byte 1, and so on.

12.1.1.3 Endian Configuration

The following endian configuration is provided by the `ENDIAN` field in the **CRCCTRL** register:

- Swap byte in half-word
- Swap half word

Input data width is four bytes, hence the configuration only affects the four-byte word. The `ENDIAN` bit field supports the following configurations, assuming the input word is {B3, B2, B1, B0}

Table 12-1. Endian Configuration

| ENDIAN Encoding | Definition | Configuration |
|-----------------|--|------------------|
| 0x0 | Configuration unchanged. | {B3, B2, B1, B0} |
| 0x1 | Bytes are swapped in half-words but half-words are not swapped | {B2, B3, B0, B1} |
| 0x2 | Half-words are swapped but bytes are not swapped in half-word. | {B1, B0, B3, B2} |
| 0x3 | Bytes are swapped in half-words and half-words are swapped. | {B0, B1, B2, B3} |

Bit reversal is supported by the `BR` bit in the **CRCCTRL** register. The bit reversal operation works in tandem with endian control. For example, the above table with the `BR` option set would look like this:

Table 12-2. Endian Configuration with Bit Reversal

| ENDIAN Encoding | Initial Endian Configuration | Configuration with Bit Reversal (BR = 1) |
|-----------------|---|--|
| 0x0 | Configuration unchanged. {B3[31:24], B2[23:16], B1[15:8], B0[7:0]} | B3[24:31], B2[16:23], B1[8:15], B0[0:7] |

Table 12-2. Endian Configuration with Bit Reversal (continued)

| ENDIAN Encoding | Initial Endian Configuration | Configuration with Bit Reversal (BR = 1) |
|-----------------|---|--|
| 0x1 | Bytes are swapped in half-words but half-words are not swapped {B2[23:16], B3[31:24], B0[7:0], B1[15:8]} | B2[16:23],B3[24:31],B0[0:7],B1[8:15] |
| 0x2 | Half-words are swapped but bytes are not swapped in half-word. {B1[15:8], B0[7:0], B3[31:24], B2[23:16]} | B1[8:15],B0[0:7],B3[24:31],B2[16:23] |
| 0x3 | Bytes are swapped in half-words and half-words are swapped {B0[7:0], B1[15:8], B2[23:16], B3[31:24]} | B0[0:7],B1[8:15],B2[16:23],B3[24:31] |

12.2 Initialization and Configuration

The following describes the initialization and configuration procedures of the CRC module.

12.2.1 CRC Initialization and Configuration

The CRC engine works in push through mode, which means it works on streaming data. This section describes the steps for initializing the CRC module:

1. Enable the CRC by setting the **R0** bit in the CRC and Cryptographic Modules (RCGCCM) register, System Control offset 0x674.
2. Configure the desired CRC data size, bit order, endian configuration and CRC type by programming the **CRC Control (CRCCTRL)** register, offset 0x400.
3. If the CRC value has not been initialized to all 0s or all 1s using the **INIT** field in the **CRCCTRL** register, program the initial value in the **CRC SEED/Context (CRCSEED)** register, offset 0x410.
4. Repeatedly write the **DATAIN** field in the **CRC Data Input (CRCDIN)** register, offset 0x414. If the **SIZE** bit in the **CRCCTRL** register is set to select byte, the CRC engine operates in byte mode and only the least significant byte is used for CRC calculation.
5. When CRC is finished, read the **CRCSEED** register for the final result. If using post-processing, the raw CRC result is stored in the **CRCSEED** register and the final, post-processed result can be read from the **CRC Post-Processing Result (CRCRSLTPP)** register, offset 0x418. Post-processing options are selectable through the **OBR** and **OLNV** bits of the **CRCCTRL** register.

Alternatively a software μ DMA channel can be configured to copy data from the source into the **CRCDIN** register. When configuring the μ DMA, the destination should be configured to not increment. For more information on how to configure the μ DMA, refer to “Micro Direct Memory Access (μ DMA)” on page 708.

12.2.1.1 Data Endian Convention for the CRC Engine

If the input stream is expressed as a byte stream, D_{in} , where $D_{in} = \{D_0, D_1, D_2, D_3, D_4, D_5, D_6, D_7, D_8, D_9, D_{11}, D_{12}, D_{13}, D_{14}, D_{15}, D_{16} \dots\}$, then data should be fed to the CRC engine as follows:

- If operating in Byte mode, the **CRCDIN** register should be written in the following order:
 1. {00, 00, 00, D0}

2. {00, 00, 00, D1}
3. {00, 00, 00, D2}
4. {00, 00, 00, D3}
5. {00, 00, 00, D4}
6. {00, 00, 00, D5}
7. {00, 00, 00, D6}
8.
9.

- If operating in word mode, the **CRC DIN** register should be written in the following order:

1. {D3, D2, D1, D0}
2. {D7, D6, D5, D4}
3. {D11, D10, D9, D8}
4.
5.

12.3 Register Map

Table 12-3 on page 982 lists the CRC Module registers. The offset listed is a hexadecimal increment to the register's address, relative to the base address 0x4403.0000.

Table 12-3. CCM Register Map

| Offset | Name | Type | Reset | Description | See page |
|--------|-----------|------|-------------|----------------------------|----------|
| 0x400 | CRCCTRL | RW | 0x0000.0000 | CRC Control | 983 |
| 0x410 | CRCSEED | RW | 0x0000.0000 | CRC SEED/Context | 985 |
| 0x414 | CRC DIN | RW | 0x0000.0000 | CRC Data Input | 986 |
| 0x418 | CRCRSLTPP | RO | 0x0000.0000 | CRC Post Processing Result | 987 |

12.4 CRC Module Register Descriptions

This section lists and describes the CRC registers, in numerical order by address offset.

Note: The CRC module can only be accessed through privileged mode. If the μ DMA is used for CRC transfers, then the μ DMA's **DMA Channel Control (DMACHCTL)** register also needs to be programmed to allow for privileged accesses.

Register 1: CRC Control (CRCCTRL), offset 0x400

The **CRC Control (CRCCTRL)** register is used to configure control of the CRC.

CRC Control (CRCCTRL)

Register 2: CRC SEED/Context (CRCSEED), offset 0x410

The **CRC SEED/Context (CRCSEED)** register is initially written with one of the following three values depending on the encoding of the **INIT** field in the **CRCCTRL** register:

- The context value written to the **CRCSEED** register. This encoding is for **SEED** values from a previous CRC calculation or a specific protocol. (**INIT**=0x0)
- 0x0000.0000 (**INIT**=0x2)
- 0x1111.1111 (**INIT**=0x3)

13 Advance Encryption Standard Accelerator (AES)

This section describes the Advanced Encryption Standard (AES) cryptographic hardware-accelerated module.

13.1 AES Overview

This section introduces the AES and describes the AES main functions and connections in the device.

The advanced encryption standard (AES) security modules provide hardware-accelerated data encryption and decryption operations based on a binary key. The AES is a symmetric cipher module that supports a 128-bit, 192-bit, or 256-bit key in hardware for both encryption and decryption. The AES module is based on a symmetric algorithm, meaning that the encryption and decryption keys are identical. To encrypt data means to convert it from plain text to an unintelligible form called cipher text. Decrypting cipher text converts previously encrypted data back to its original plain text form.

The main features of the AES accelerator are:

- Support for basic AES encrypt and decrypt operations:
 - Galois/Counter Mode (GCM), with basic GHASH operation
 - Counter Mode with CBC-MAC (CCM)
 - XTS Mode
- Availability of the following feedback operating modes:
 - Electronic Code Book Mode (ECB)
 - Cipher Block Chaining Mode (CBC)
 - Counter Mode (CTR)
 - Cipher Feedback Mode (CFB), 128-bit
 - F8 Mode
- Key sizes 128-, 192- and 256-bits
- Support for CBC_MAC and Fedora 9 (F9) authentication modes
- Basic GHASH operation (when selecting no encryption)
- Key scheduling in hardware
- Support for μ DMA transfers
- Fully synchronous design

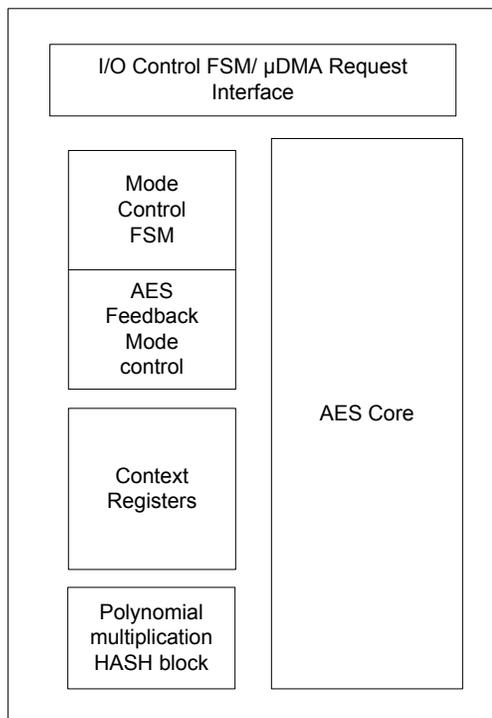

13.2 AES Functional Description

The following sections describe the features of the AES Module.

13.2.1 AES Block Diagram

Figure 13-1 on page 989 shows the AES block diagram. A single-core/dual-interface architecture is used.

Figure 13-1. AES Block Diagram

AES is an efficient implementation of the Rijndael cipher (the AES algorithm) and a 128-bit polynomial multiplication (referred to here as GHASH, as per the AES-GCM specification). Rijndael is a block cipher in which each data block is 128 bits. The polynomial multiplication multiplies two 128-bit vectors using the smallest 128-bit irreducible polynomial, represented by the following 128-bit string: $\{0^{120}\}||10000111$. The two implementations are combined into the AES wide-bus engine.

Depending on the availability of context and data, the AES wide-bus engine is automatically triggered to process the data. The AES wide-bus engine is directly connected to the context and data registers so that it can immediately start processing when all data is available. The AES wide-bus engine also interfaces to the I/O Control FSM/ μ DMA Request Interface.

AES comprises the following major functional blocks:

- Global control FSM and μ DMA interface
- Register interface module
- The AES wide-bus engine

The AES wide-bus engine, which is the major top-level component, comprises the following functional blocks:

- Mode control FSM: Manages the data flow to and from the AES wide-bus engine and starts each encryption/decryption operation.

- Feedback modes: The logic that implements the various feedback modes supported by AES.
- GHASH core: The polynomial multiplication algorithm used for AES-GCM
- AES key scheduler: Generates AES encryption and decryption (round) keys
- AES encryption core: The AES encryption algorithm
- AES decryption core: The AES decryption algorithm
- Substitution-boxes (S-Boxes): Contain AES S-Box GF(2⁸) implementations

AES encryption requires a specific number of rounds, depending on the key length. The supported key lengths are 128-, 192-, and 256-bit, which require 10, 12, and 14 rounds, respectively, or 32, 38, and 44 clock cycles, respectively, because {number of clock cycles} = 2 + 3 x {number of rounds}.

The larger key lengths provide greater encryption strength at the expense of additional rounds and therefore reduced throughput. The overall throughput of the AES executing polynomial multiplication is adjusted based on the overall cryptographic performance. The AES module contains one Electronic Codebook (ECB) core and a dedicated 32-cycle polynomial multiplication module for performing GHASH operations. Polynomial multiplication operates in parallel with the AES core, if data is available for both modules.

Depending on the key size (128/192/256 bits), this core requires 32, 38, or 44 clock cycles to process one 128-bit data block. While one data block processes, the next block can be preloaded immediately. When a block is preloaded, the previous block must finish before additional data can be loaded. Therefore, once the pipeline is full, sequential data blocks can be passed every 32, 38, or 44 clock cycles.

13.2.1.1 Interfaces

The interface signals to the AES module can be grouped into the following four categories:

- Clock and reset signals
- Register interface
- μ DMA/INT interface, used to request new context and packet data or to indicate available result data (encrypted/decrypted data or authentication result)

13.2.1.2 Register Interface

The register interface block performs all address decoding and control. However, not all registers are located in this block. The context and data input registers are in the AES wide-bus engine. The data output registers are available in this block.

13.2.1.3 AES Wide-Bus Engine

The AES wide-bus engine performs the cryptographic operations. The composition of the AES core is:

- The main data path operates on the input block, performing the required substitution, shift, and mix operations.
- The key scheduler generates the round keys. A new subkey is generated and XORed with the data each round.

AES Key Scheduler

The AES key scheduler generates the round keys. During each round, a new subkey is generated from the input key to be XORed with the data. Round keys are generated on-the-fly and parallel to data processing to minimize register requirements.

For encryption operations, the key sequencer transfers the initial key data to the AES core. For decryption operations, the key scheduler must provide the final subkey to the AES core so it can generate the subkeys in reverse order.

AES Encryption Core

The AES encryption core implements the Rijndael algorithm as specified in [FIPS-197]. This core operates on the input block and performs the required substitution, shift, and mix operations. For each round, the encryption core receives the proper round key from the AES key scheduler. A fundamental component of the AES algorithm is the S-Box. The S-Box provides a unique 8-bit output for each 8-bit input. This implementation of the AES encryption core has a 64-bit data path.

AES Decryption Core

The architecture of the AES decryption core is generally the same as the architecture of the encryption core. One difference is that the generation of round keys for decryption requires an initial conversion of the input key (always supplied by the host in the form of an encryption key) to the corresponding decryption key. This conversion is done by performing a dummy encryption operation and storing the final round key as a decryption key. The key scheduler is then reversed to generate the round keys for the decryption operation. Consequently, for each sequence of decryption operations under the same key, a single throughput reduction equal to the time to encrypt a single block occurs. Once a decryption key is generated, subsequent decryption operations with the same key use this generated decryption key directly.

AES Feedback Mode Block

The AES feedback mode block buffers the feedback parameters and controls the various feedback modes. For more information about the ECB, CBC, CTR, and CFB modes of operation, see the [NIST-SP800-38A](#) specification.

CTR implements the standard incrementing function, as described in the NIST-SP800-38A specification, with m set to 16 or a multiple of 32.

AES-XTS mode requires a polynomial multiplication for initialization vector (IV) generation of the AES operation. This multiplication can be simplified when the first result is available due to the definition and use of the block number within a unit. The input for the polynomial multiplication is not directly j , but α^j , where $\alpha = x^2$ in the $GF(2^{128})$ domain.

In addition, f8 encryption/decryption mode and f9 and (X)CBC-MAC authentication modes are available.

GHASH Block

The data sequencer manages the data flow to and from the AES core. For data input, the data sequencer monitors the input buffer until a 16-byte block is available. If the AES core is idle, the data sequencer writes this data block to the internal working registers of the AES core, thus clearing the buffer for the next block.

After completing an encryption or decryption operation, the data sequencer writes the AES output to the output buffer. If the output buffer is full at the time of completion, the AES core is held until the buffer clears. Although the data sequencer is designed to support uninterrupted packet encryption, the host must properly manage the input and output packet buffers to achieve optimal performance.

13.2.2 AES Algorithm

The AES algorithm generates block ciphers. The AES block size is 16 bytes. The AES key(s) can be coded on 128, 192, or 256 bits. The larger key sizes provide a higher level of security, but at the cost of a moderate decrease in throughput.

For the AES algorithm:

- The length of the input and output blocks is 128 bits, which is represented by $N_b = 4$, which reflects the number of 32-bit words.
- The length of the cipher key (K) is 128, 192, or 256 bits. The key length is represented by $N_k = 4, 6, \text{ or } 8$, which reflects the number of 32-bit words in the cipher key.
- The number of rounds to be performed during the execution of the algorithm is dependent on the key size. The number of rounds is represented by N_r , where $N_r = 10$ when $N_k = 4$ (128-bit key); $N_r = 12$ when $N_k = 6$ (192-bit key); and $N_r = 14$ when $N_k = 8$ (256-bit key).

Table 13-1 on page 992 lists the combinations of keys, blocks, and rounds.

Table 13-1. Key-Block-Round Combinations

| Key | Key Length (N_k) | Block Size (N_b) | Number of Rounds (N_r) |
|----------|----------------------|----------------------|----------------------------|
| 128 bits | 4 | 4 | 10 |
| 192 bits | 6 | 4 | 12 |
| 256 bits | 8 | 4 | 14 |

The AES algorithm for cipher and inverse cipher uses a round function composed of four different byte-oriented transformations:

- Byte substitution using a substitution table (S-Box)

This transformation is a non-linear byte substitution that operates independently on each byte of the state (the state is an intermediate processed block of 128 bits inside the AES; the state is arranged as an array of $[4 \times N_k]$ bytes) using an S-Box. This S-Box transformation is reversible.
- Shifting rows of the state array by different offsets

In this transformation, the bytes in the last three rows of the state are cyclically shifted over different numbers of bytes (offsets). The first row ($r = 0$) is not shifted.
- Mixing the data within each column of the state array

This transformation operates on the state column-by-column, treating each column as a four-term polynomial. The columns are considered polynomials over $GF(2^8)$ and multiplied modulo $x^4 + 1$ with a fixed polynomial $a(x)$.
- Adding a round key to the state

In this transformation, a round key is added to the state by a simple bitwise XOR operation. Each round key consists of N_b words from the key schedule.

The AES algorithm takes the cipher key (K) and performs a key expansion routine to generate a key schedule. The key expansion generates a total of $N_b \times (N_r + 1)$ words: The algorithm requires an initial set of N_b words, and each of the N_r rounds requires N_b words of key data. The resulting key schedule consists of a linear array of 4-byte words, denoted $[w_i]$, with i in the range $0 \leq i < N_b \times (N_r + 1)$.

13.2.3 AES Operating Modes

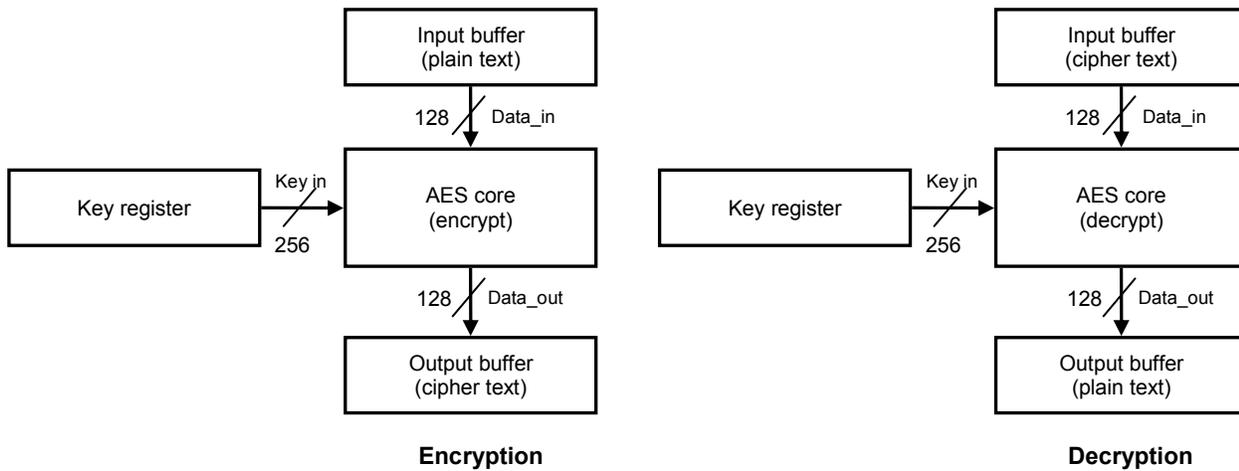

13.2.3.1 Supported Modes of Operation

ECB Feedback Mode

Figure 13-2 on page 993 shows the basic ECB feedback mode of operation, where the input data is passed directly to the basic cryptographic core and the output is passed directly to the output buffer.

For decryption, the cryptographic core operates in reverse: the decryption data path is used for data processing, whereas encryption uses the encryption data path.

Figure 13-2. AES - ECB Feedback Mode

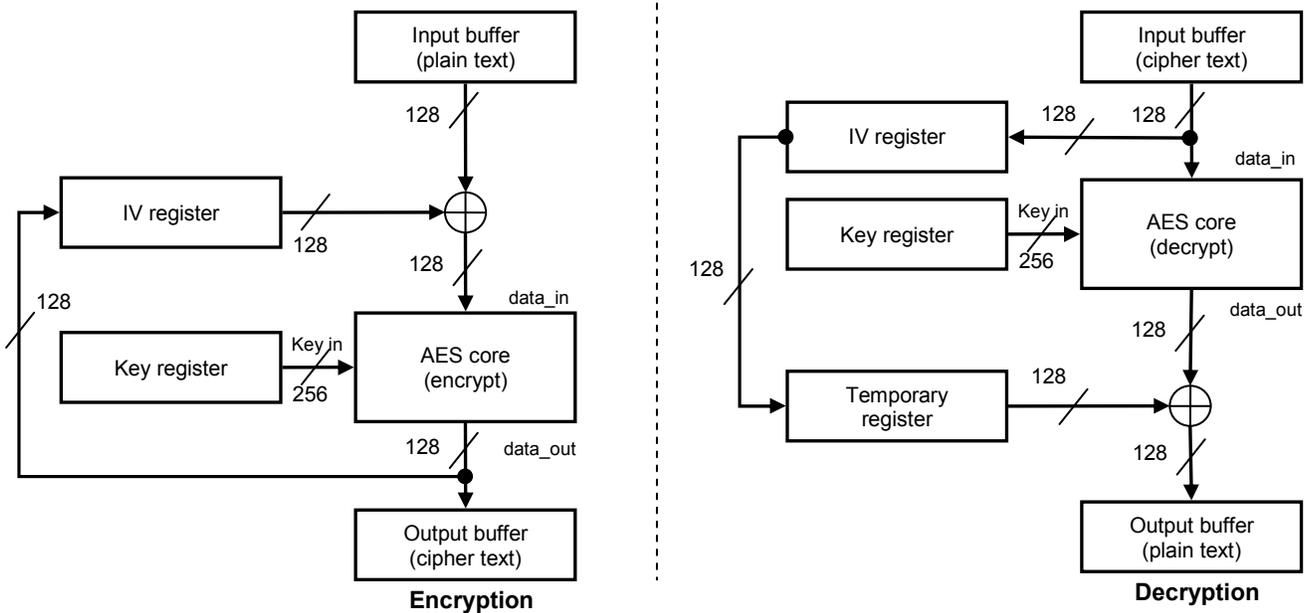

CBC Feedback Mode

Figure 13-3 on page 994 shows the CBC feedback mode of operation, where the input data is XORed with the IV before it is passed to the basic cryptographic core. The output of the cryptographic core passes directly to the output buffer and becomes the next IV.

The operation is reversed for decryption, resulting in an XOR at the output of the cryptographic core. The input cipher text of the current operation is the IV for the next operation.

Figure 13-3. AES - CBC Feedback Mode

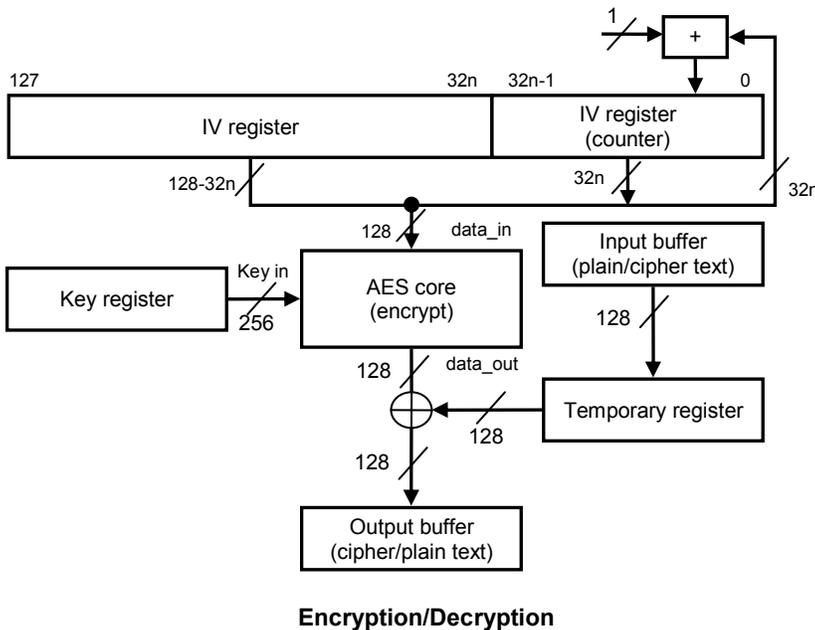

CTR and ICM Feedback Modes

Figure 13-4 on page 994 shows the counter feedback (CTR/ICM) mode of operation. This operation encrypts the IV. The output of the cryptographic core (encrypted IV) is XORed with the data, thus creating the output result.

The IV is built out of two components: a fixed part and a counter part. The counter part is incremented with each block. The counter width is selectable per context and can be 16, 32, 64, 96, or 128 bits wide. In this mode, encryption and decryption use the same operation.

Figure 13-4. AES Encryption With CTR/ICM Mode

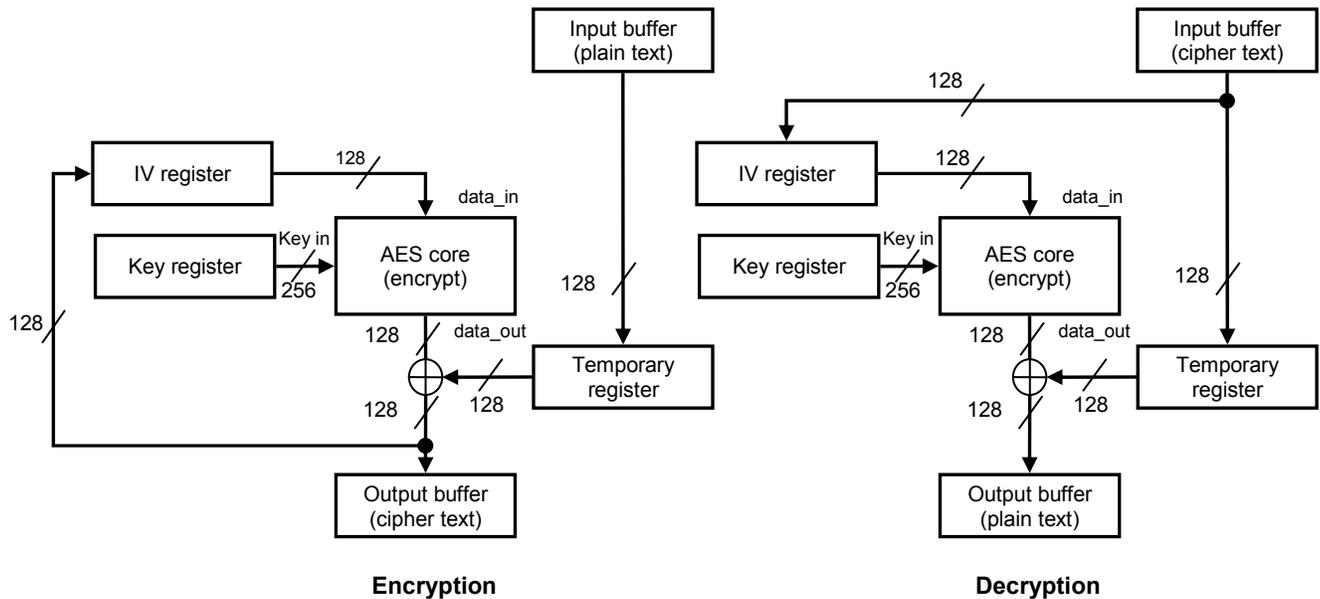

Note: The value for n can be 1, 2, 3, or 4 for CTR mode and is ½ for ICM mode.

CFB Mode

Figure 13-5 on page 995 shows the full block (128 bits) CFB mode of operation for encryption and decryption. The input for the cryptographic core is the IV; the result is XORed with the data. The result is fed back through the IV register as the next input for the cryptographic core. The decryption operation is reversed, but the cryptographic core still performs encryption.

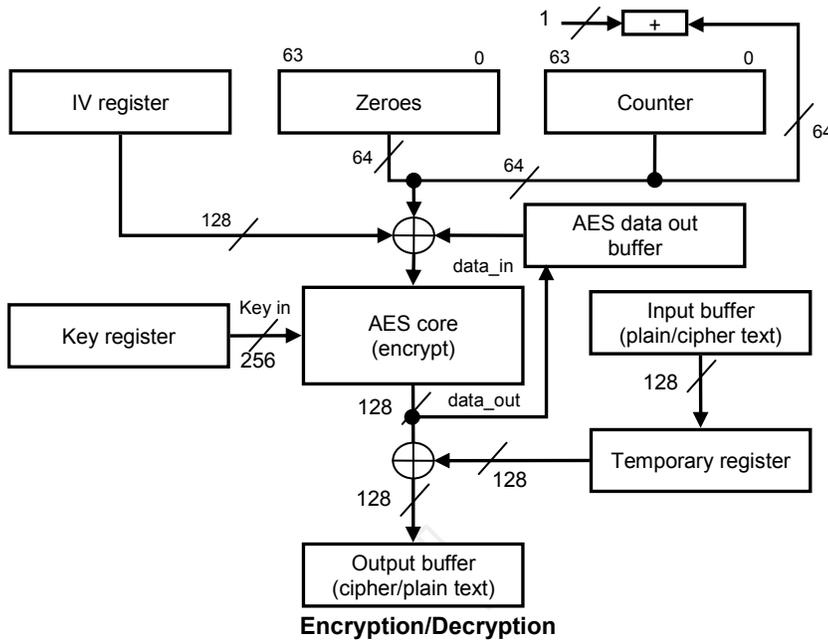

Figure 13-5. AES - CFB Feedback Mode

F8 Mode

Figure 13-6 on page 996 shows the F8 feedback mode of operation for encryption and decryption. The input to the cryptographic core is the result of the XOR operation of the previous cryptographic core output, a constant IV, and a block counter. The output of the cryptographic core is XORed with the input to create the result. In this mode, encryption and decryption use the same operations.

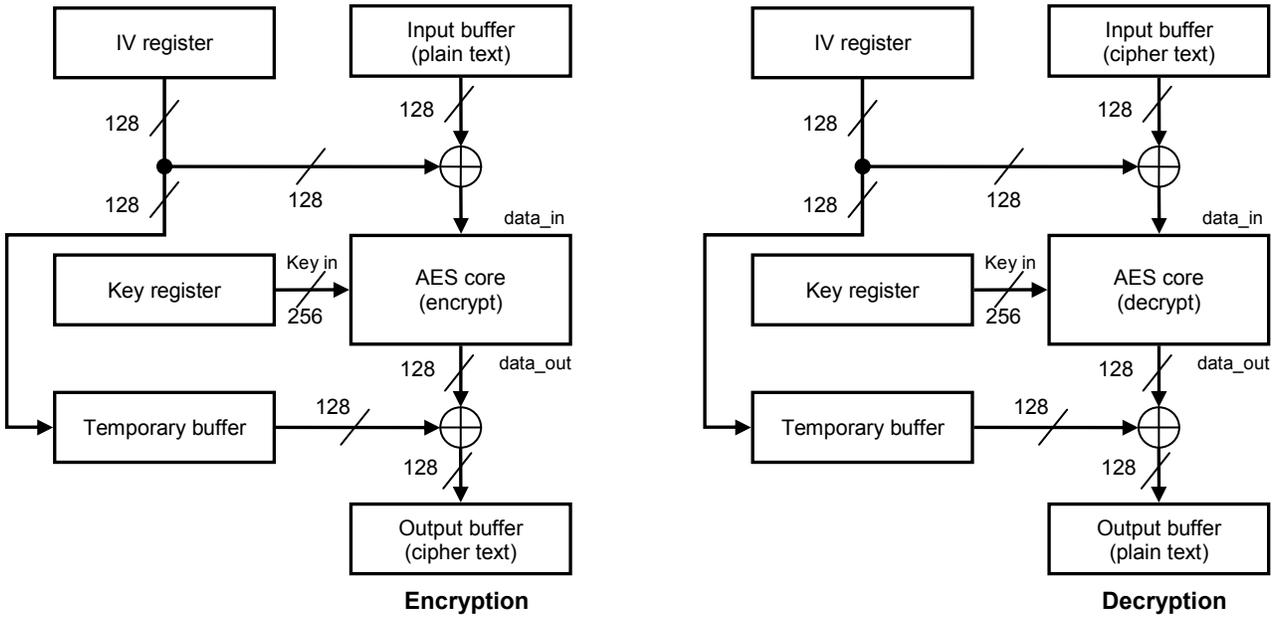

Figure 13-6. AES - F8 Mode

XTS Operation

Figure 13-7 on page 996 shows the XTS mode of operation for encryption and decryption. The input to the cryptographic core is XORed with the IV; the output of the cryptographic core is XORed with the same IV. For decryption, the cryptographic core operates in reverse, but the XOR operations are the same.

Figure 13-7. AES - XTS Operation

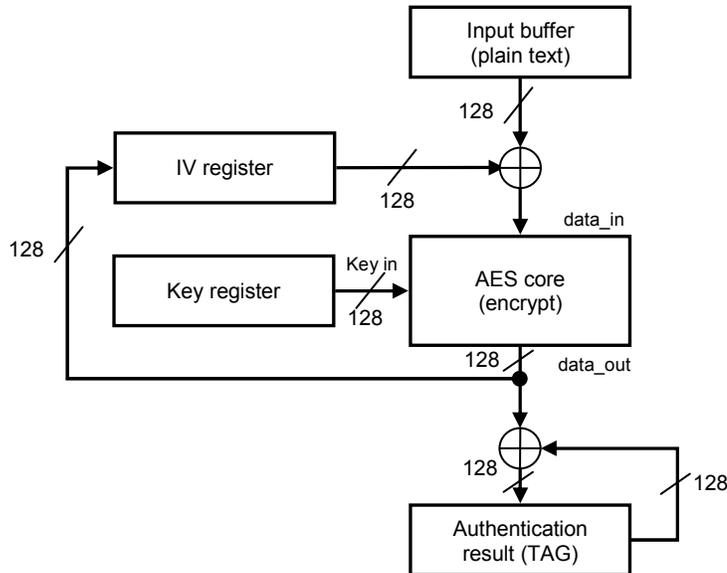

Note: The IV is created with an initial encryption, followed by an LFSR operation for each new block.

F9 Operation

Figure 13-8 on page 997 shows the F9 authentication mode of operation, where the input to the cryptographic core is XORed with the IV, and the output is XORed with the previous result to create the next result. The cryptographic core output is fed back as IV for the next block. The result is the output of the last XOR operation of the cryptographic core output.

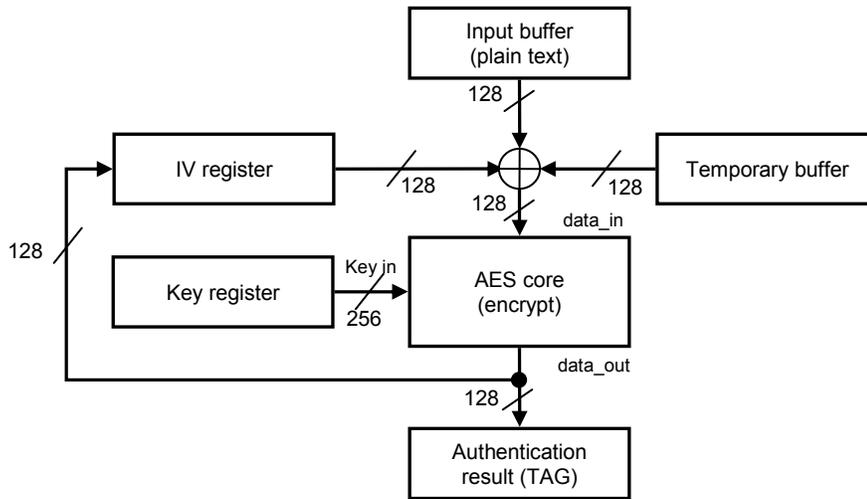

Figure 13-8. AES - F9 Operation

CBC-MAC Operation

Figure 13-9 on page 998 shows the CBC-MAC authentication mode of operation, where the input to the cryptographic core is XORed with the IV. The cryptographic core output is then fed back as IV for the next block. The last data input block is XORed with an additional input value stored in the temporary buffer; this can be any precalculated value and is dependent on the alignment of the last input block. The result is the cryptographic core output of the last encryption operation.

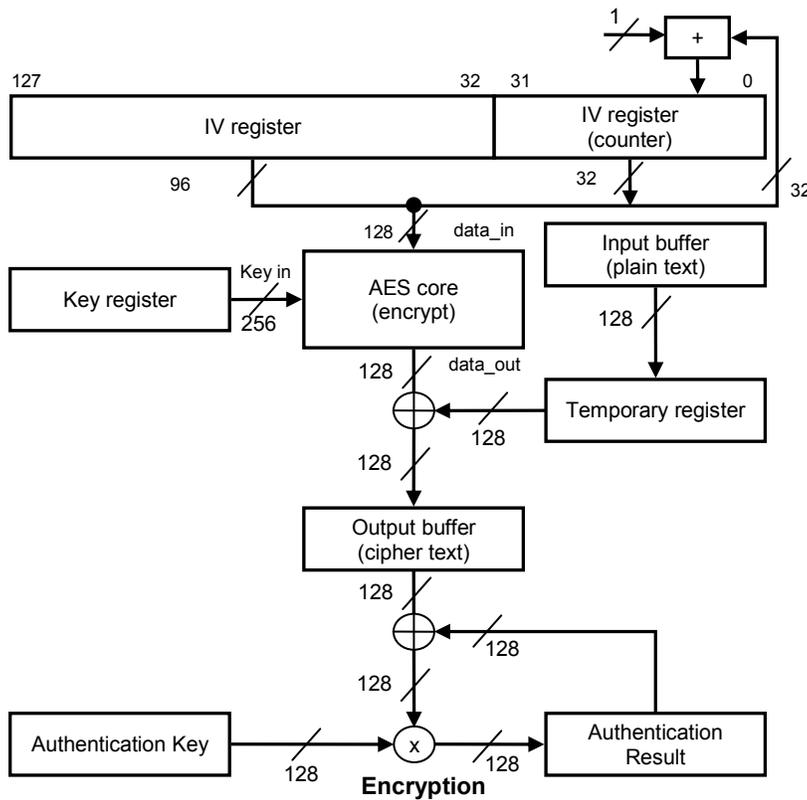

Figure 13-9. AES - CBC-MAC Authentication Mode

GCM Operation

Figure 13-10 on page 999 shows one round of a GCM operation for encryption and decryption. A 32-bit counter is used as IV (as it is for CTR mode). The data is encrypted in the same way as in CTR mode, by XORing the cryptographic core output with the input. After the encryption/decryption, the ciphertext is XORed with the intermediate authentication result. The XORed result is used as input for the polynomial multiplication to create the next (intermediate) authentication result. For more information about the GCM protocol, see the section called “GCM Protocol Operation” on page 1000.

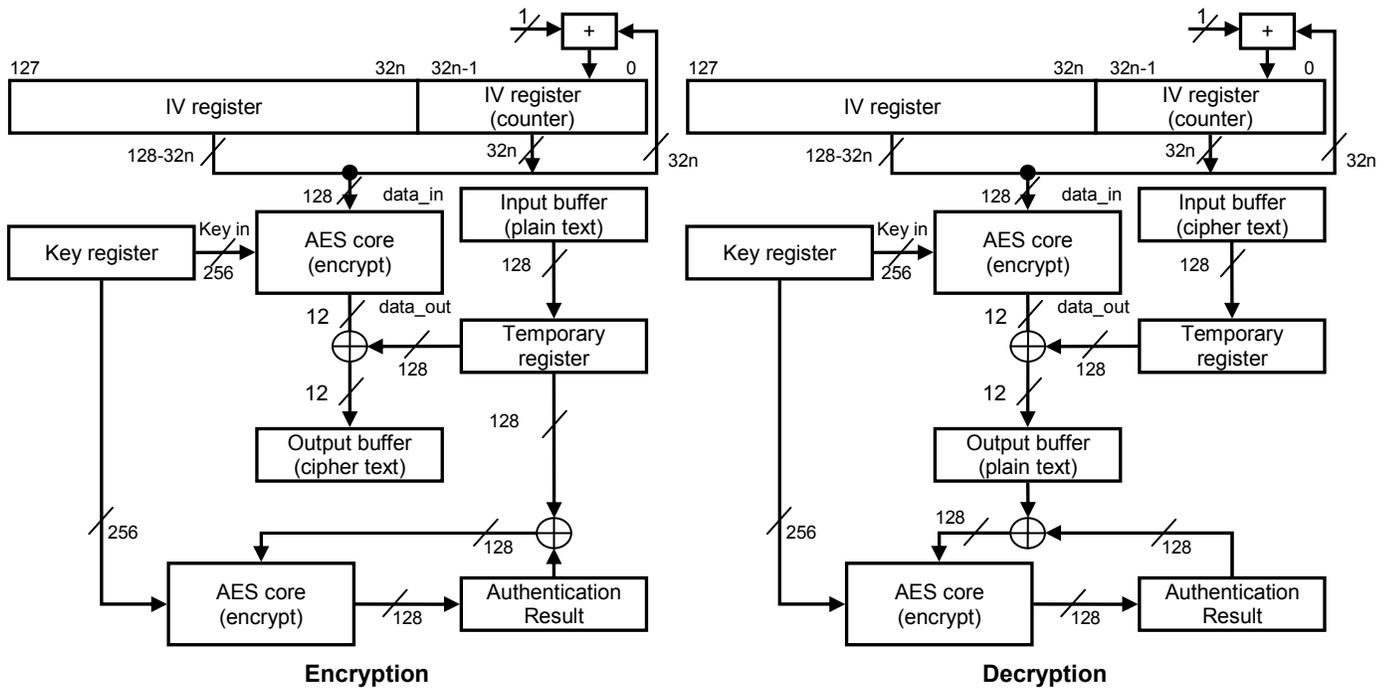

Figure 13-10. AES - GCM Operation

CCM Operation

Figure 13-11 on page 1000 shows one round of a CCM (counter with CBC-MAC) operation for encryption and decryption. A 32-bit counter is used as IV (as it is for CTR mode). The data is encrypted in the same way as in CTR mode, by XORing the cryptographic core output with the input. Immediately after the encryption operation, the plaintext is XORed with the intermediate authentication result. The XOR result is used as input for a second encryption operation to calculate the next (intermediate) authentication result.

Figure 13-11. AES - CCM Operation

13.2.3.2 Extended and Combined Modes of Operations

This section describes the protocols (or autonomous precalculations) supported by the AES wide-bus engine.

GCM Protocol Operation

A GCM protocol operation is a combined operation consisting of encryption/decryption and authentication. A part of the input data stream can be authenticated only, while normally most of the input data is encrypted/decrypted and authenticated. The authentication-only data must always be in front of the data requiring encryption. Within GCM, the authentication-only data is called the additional authentication data (AAD). The AAD is fetched independently of other data.

The intermediate (temporary) result data is used as input to the remaining authentication operation. Because the authentication operation does not require the cryptographic core but only the polynomial multiplication, encryption/decryption and authentication can be performed in parallel. After encryption of the last data block, additional polynomial multiplication and encryption are required to authenticate a 128-bit length vector and finally encrypt the authentication result.

CCM Protocol Operation

The CCM protocol operation is a combined operation consisting of encryption/decryption and authentication. The authentication and encryption/decryption operations use the cryptographic core; these are executed sequentially on the AES core. A part of the data stream can require authentication only. The authentication-only data must always be in front of the data requiring encryption.

Authentication starts with the encryption of a predefined block B0. This block consists of flags, nonce, and message length. The next blocks contain the authentication data length concatenated with the authentication-only data. After processing the authentication-only data, the encryption/decryption operations are performed, each followed by the related authentication of the plaintext data block (which equals the input in the case of encryption, and the output in the case of

decryption). The final authentication result must be encrypted using the output of the encryption of the IV block A0. This block contains the IV (consisting of flags and nonce) concatenated with the counter, which is zero for A0.

13.2.4 AES Software Reset

To perform a software reset of the AES module, write a 1 to the `SOFTRESET` bit in the **AES System Configuration (AES_SYSCONFIG)** register. The `RESETDONE` bit in the **AES Secure System Status (AES_SYSSTATUS)** register indicates that the software reset is complete when its value is 1. When the software reset completes, the `SOFTRESET` bit in the **AES_SYSCONFIG** register is automatically reset. Software must ensure that the software reset completes before doing any operations.

The behavior of the software reset is the same as the hardware reset, except that the software reset bit resets this module without affecting the reset core domain of the entire device.

13.2.5 Power Management

To save power, the application can disable the clock to the AES module when not in use. The AES is clock gated by setting the `AESCFG` bit in the **Cryptographic Modules Clock Gating Request (CCMCGREQ)** register, CRC and Cryptographic Modules (CCM) offset 0x204. The AES in addition to the DES, SHA/MD5 and CRC can also be clock gated as a group by setting the `D0` bit in the **CRC and Cryptographic Modules (DCGCCM)** register, System Control Module offset 0x874.

13.2.6 Hardware Requests

The AES module can assert a μ DMA request for context in, context out, input data, or output data read. The **AES uDMA Interrupt Mask (AES_DMAIM)** register can be set to generate interrupts during the following events:

- Context In μ DMA request (AES0 Cin)
- Context Out μ DMA request (AES0 Cout)
- Data In μ DMA request (AES0 Din)
- Data Out μ DMA request (AES0 Dout)

The AES Module can be programmed to assert an interrupt when the uDMA has completed its last transfer. Please refer to “AES μ DMA Interrupt Register Descriptions (CCM Offset)” on page 1033 for more information.

If context and data transfers are to be handled through software, then the **AES Interrupt Enable (AES_IRQENABLE)**, offset 0x090, can be used to enable interrupt triggering when context out, context in, data in or data out is ready. The **AES Interrupt Status (AES_IRQSTATUS)**, offset 0x08C, indicates when an interrupt is triggered.

Table 13-2. Interrupts and Events

| Event | Description |
|--|--------------------------|
| <code>AES_IRQSTATUS[3]: CONTEXT_OUT</code> | Context output interrupt |
| <code>AES_IRQSTATUS[2]: DATA_OUT</code> | Data output interrupt |
| <code>AES_IRQSTATUS[1]: DATA_IN</code> | Data input interrupt |
| <code>AES_IRQSTATUS[0]: CONTEXT_IN</code> | Context input interrupt |

13.3 AES Performance Information

Table 13-3 on page 1002 lists the performance for all supported key sizes and modes of operations. It assumes that the engine is kept fully utilized (that is, the host is supplying input blocks and retrieving output blocks in such a way that the engine never has to wait for input), and that the previous output has been retrieved before the next output is ready.

Table 13-3. AES Module Performance (Input/Output Block Size = 128)

| Key Size | Mode of Operation | Cycles per Block ^a | Throughput (bits/cycle) |
|---------------------------|---------------------------|-------------------------------|-------------------------|
| 128 | ECB-encrypt / decrypt | 32 | 4.00 |
| | CBC-decrypt | | |
| | CTR/ICM-encrypt / decrypt | | |
| | CFB128-decrypt | | |
| | CBC-encrypt | 33 | 3.88 |
| | OFB-encrypt / decrypt | | |
| | f8-encrypt / decrypt | | |
| | CFB128-encrypt | | |
| | XTS-encrypt / decrypt | | |
| | GCM-outbound / inbound | 66 | 1.94 |
| | CCM-encrypt / decrypt | | |
| | CBC-MAC ^b | 33 | 3.88 |
| | f9 ^b | | |
| | 192 | ECB-encrypt / decrypt | 38 |
| CBC-decrypt | | | |
| CTR/ICM-encrypt / decrypt | | | |
| CFB128-decrypt | | | |
| CBC-encrypt | | 39 | 3.28 |
| OFB-encrypt / decrypt | | | |
| f8-encrypt / decrypt | | | |
| CFB128-encrypt | | | |
| XTS-encrypt / decrypt | | | |
| GCM-outbound / inbound | | 78 | 1.64 |
| CCM-encrypt / decrypt | | | |
| CBC-MAC ^b | | 39 | 3.28 |
| f9 ^b | | | |

Table 13-3. AES Module Performance (Input/Output Block Size = 128) (continued)

| Key Size | Mode of Operation | Cycles per Block ^a | Throughput (bits/cycle) |
|----------|---------------------------|-------------------------------|-------------------------|
| 256 | ECB-encrypt / decrypt | 44 | 2.91 |
| | CBC-decrypt | | |
| | CTR/ICM-encrypt / decrypt | | |
| | CFB128-decrypt | | |
| | CBC-encrypt | 45 | 2.84 |
| | OFB-encrypt / decrypt | | |
| | f8-encrypt / decrypt | | |
| | CFB128-encrypt | | |
| | XTS-encrypt / decrypt | | |
| | GCM-outbound inbound | 90 | 1.42 |
| | CCM-encrypt / decrypt | | |
| | CBC-MAC ^b | 45 | 2.84 |
| | f9 ^b | | |

a. Standard Block Size (128 bits)

b. Input Only

The "Cycles per block" numbers do not apply to the first block after selection of a new key and/or mode of operation, or the last block before switching to a new algorithm. The next table indicates the additional clock cycles; required for changing context data.

Table 13-4. AES Module Packet Mode Switch Overhead

| New Context | Cycles needed for first block/and to finish the last block | Total |
|-----------------------------------|--|-------|
| mode is encrypt | 1 / 1 | 2 |
| mode is decrypt, key size is 128 | 32 / 1 | 33 |
| mode is decrypt, key size is 192 | 38 / 1 | 39 |
| mode is decrypt, key size is 256 | 44 / 1 | 45 |
| mode is XTS, key size is 128 | 34 / 1 | 35 |
| mode is XTS, key size is 192 | 40 / 1 | 41 |
| mode is XTS, key size is 256 | 46 / 1 | 47 |
| outbound GCM, AES key size is 128 | 33 ^a / 52 | 85 |
| outbound GCM, AES key size is 192 | 39 ^a / 52 | 91 |
| outbound GCM, AES key size is 256 | 45 ^a / 52 | 97 |
| inbound GCM, AES key size is 128 | 33 ^a / 27 | 60 |
| inbound GCM, AES key size is 192 | 39 ^a / 27 | 66 |
| inbound GCM, AES key size is 256 | 45 ^a / 27 | 72 |
| outbound CCM, AES key size is 128 | 33 ^b / 33 | 66 |
| outbound CCM, AES key size is 192 | 39 ^b / 39 | 78 |
| outbound CCM, AES key size is 256 | 45 ^b / 45 | 90 |
| inbound CCM, AES key size is 128 | 33 ^b / 33 | 66 |
| inbound CCM, AES key size is 192 | 39 ^b / 39 | 78 |

Table 13-4. AES Module Packet Mode Switch Overhead (continued)

| New Context | Cycles needed for first block/and to finish the last block | Total |
|----------------------------------|--|-------|
| inbound CCM, AES key size is 256 | 45 ^b / 45 | 90 |

- a. Numbers for regular GCM mode (H is precalculated and Y0-encrypted need to be calculated internally using the new IV). If H needs to be calculated by the core (complete GCM mode), this number needs to be doubled. If Y0-encrypted is not calculated (forced to zero, such that the hash result is not encrypted) this number is zero.
- b. Numbers for regular CCM mode. Dependent on the AAD length it is possible that one additional encryption needs to be done to finalize the AAD authentication; if the additional operation is required, this number needs to be doubled.

13.4 AES Module Programming Guide

13.4.1 AES Low - Level Programming Models

This section describes the low-level hardware programming sequences for configuring and using the AES Module.

13.4.1.1 Global Initialization

The following list describes the requirements for initializing the AES and surrounding modules when AES is used for the first time after a device reset.

1. When reset has completed, enable the AES by setting the `R0` bit in the **CRC and Cryptographic Modules Run Mode Clock Gating Control (RCGCCM)**, System Control offset 0x674. When the `R0` bit is set in the **CRC and Cryptographic Modules Peripheral Ready (PRCCM)**, System Control offset 0xA74 register, the AES is powered and ready to be configured.
2. Configure the AES μ DMA channels for Context In, Context Out, Data In, and/or Data Out by programming the appropriate encoding value in the **DMA Channel Map Select n (DMACHMAPn)** register in the μ DMA module, offset 0x510. For more information on how to program channel assignments as well as enabling burst and the configured channels, refer to “Micro Direct Memory Access (μ DMA)” on page 708.
3. Execute a software reset by setting the `SOFTRESET` bit in the **AES_SYSCONFIG** register. When reset is complete, the `RESETDONE` bit reads as 1 in the **AES_SYSSTATUS** register.
4. If the AES channels are configured in the μ DMA, enable the required AES DMA requests by programming bits [9:5] of the **AES_SYSCONFIG** register, in addition to the completion interrupts in the **AES DMA Interrupt Mask (AES_DMAIM)** register, CCM offset 0x020.
5. Specify the size of the keys by programming the `KEY_SIZE` bit field in the **AES_CTRL** register.
6. Load **AES Key 1 (AES_KEY1_n)** register.
7. Load **AES Key 2 (AES_KEY2_n)** register if it is used by the configuration mode. Refer to Table 13-6 on page 1012 for information regarding which configuration modes require a load to this register.
8. Configure the AES for the appropriate encryption/decryption mode (see the section called “Subsequence: Initialize CCM AES Core Mode” on page 1005 through the section called “Subsequence: Initialize CBC AES Core Mode” on page 1006).
9. Select encryption or decryption by programming the `DIRECTION` bit in the **AES Control (AES_CTRL)** register, offset 0x050.

13.4.1.2 Initialization Subsequence

The following sections list the initialization subsequences for the available encryption/decryption modes:

Subsequence: Initialize CCM AES Core Mode

The CCM mode initialization is as follows:

1. Define the width of the length field and the length of the authentication field by programming the `CCM_L` and `CCM_M` bit fields in the **AES_CTRL** register at offset 0x050.
2. Enable counter mode by setting the `CTR` bit in the **AES_CTRL** register.
3. Load the authentication data length in the `AUTH` field of the **AES Authentication Data Length (AES_AUTH_LENGTH)** register at offset 0x05C.
4. Select the IV counter by programming the `CTR_WIDTH` field in the **AES_CTRL** register.
5. Load the **AES Initialization Vector Input n (AES_IV_IN_n)** registers at offset 0x040 to 0x04C.

Subsequence: Initialize GCM AES Core Mode

The following steps to enable GCM mode is as follows:

1. Enable counter mode by setting the `CTR` bit in the **AES_CTRL** register.
2. Load the authentication data length in the `AUTH` field of the **AES Authentication Data Length (AES_AUTH_LENGTH)** register at offset 0x05C.
3. Select the IV counter by programming the `CTR_WIDTH` field in the **AES_CTRL** register.
4. Load the **AES Initialization Vector Input n (AES_IV_IN_n)** registers at offset 0x040 to 0x04C.

Subsequence: Initialize CBC-MAC AES Core Mode

To initialize CBC-MAC Mode:

1. Enable CBC-MAC Mode by setting the `CBCMAC` bit in the **AES_CTRL** register.
2. Select encryption mode by setting the `DIRECTION` bit in the **AES_CTRL** register at offset 0x050.
3. Load the **AES Initialization Vector Input n (AES_IV_IN_n)** registers at offset 0x040 to 0x04C.

Subsequence: Initialize F9 AES Core Mode

The steps for configuring the AES for F9 mode is as follows:

1. Enable F9 Mode by setting the `F9` bit in the **AES_CTRL** register.
2. Set the key size to 128 bits by programming the `KEY_SIZE` field to 0x1 in the **AES_CTRL** register.
3. Load the **AES Initialization Vector Input n (AES_IV_IN_n)** registers at offset 0x040 to 0x04C.

Subsequence: Initialize F8 AES Core Mode

The steps for configuring the AES for F8 mode is as follows:

1. Enable F8 Mode by setting the F8 bit in the **AES_CTRL** register.
2. Select the counter width by programming the **CTR_WIDTH** field in the **AES_CTRL** register.
3. Set the key size to 128 bits by setting the **KEY_SIZE** field to 0x1 in the **AES_CTRL** register.
4. Load the **AES Initialization Vector Input n (AES_IV_IN_n)** registers at offset 0x040 to 0x04C.

Subsequence: Initialize XTS AES Core Mode

The steps for XTS mode configuration are as follows:

1. Enable XTS Mode by configuring the **XTS** field in the **AES_CTRL** register.
2. If the **XTS** field in the **AES_CTRL** register indicates that the AAD length is required, load the AAD length in the **AES_AUTH_LENGTH** register.
3. Load the **AES Initialization Vector Input n (AES_IV_IN_n)** registers at offset 0x040 to 0x04C.

Subsequence: Initialize CFB AES Core Mode

To initialize the AES code for CFB mode:

1. Enable CFB Mode by setting the **CFB** bit in the **AES_CTRL** register.
2. Load the **AES Initialization Vector Input n (AES_IV_IN_n)** registers at offset 0x040 to 0x04C.

Subsequence: Initialize ICM AES Core Mode

To initialize the AES code for ICM mode:

1. Enable ICM Mode by setting the **ICM** bit in the **AES_CTRL** register.
2. Configure for a 16-bit counter by programming the **CTR_WIDTH** to 0x0 in the **AES_CTRL** register.
3. Load the **AES Initialization Vector Input n (AES_IV_IN_n)** registers at offset 0x040 to 0x04C.

Subsequence: Initialize CTR AES Core Mode

To initialize CTR mode:

1. Enable CTR Mode by setting the **CTR** bit in the **AES_CTRL** register.
2. Select counter width by programming the **CTR_WIDTH** in the **AES_CTRL** register.
3. Load the **AES Initialization Vector Input n (AES_IV_IN_n)** registers at offset 0x040 to 0x04C.

Subsequence: Initialize CBC AES Core Mode

To configure CBC mode:

1. Enable CBC Mode by setting the **MODE** bit in the **AES_CTRL** register.
2. Load the **AES Initialization Vector Input n (AES_IV_IN_n)** registers at offset 0x040 to 0x04C.

13.4.1.3 Operational Modes Configuration

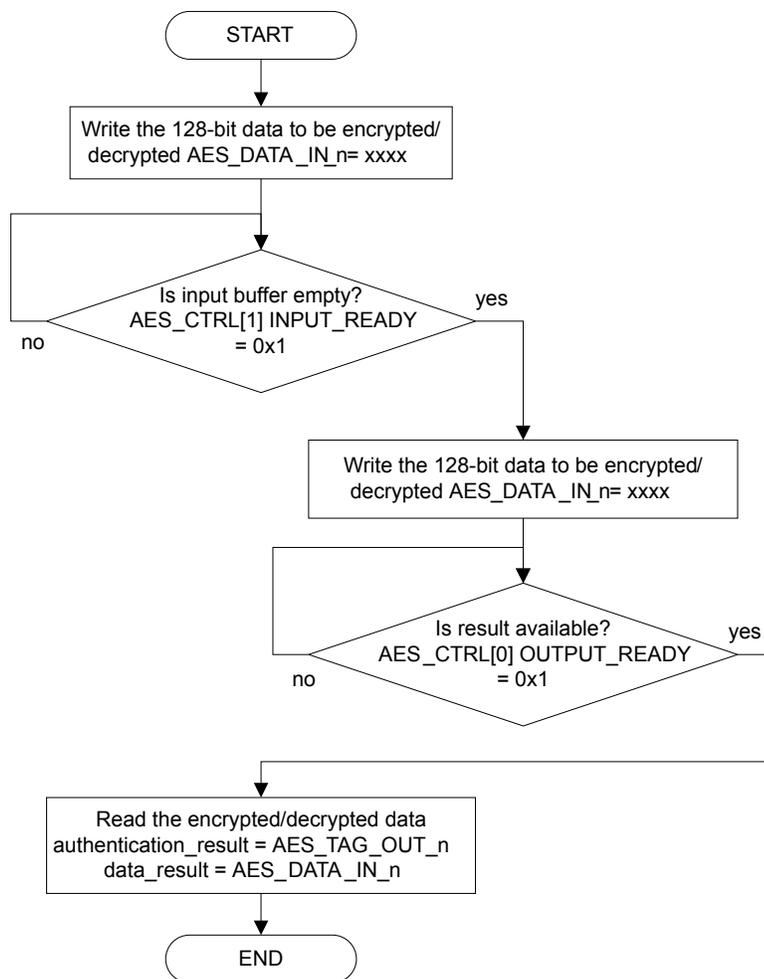

AES Polling Mode

Main Sequence: AES Polling Mode

Figure 13-12 on page 1007 shows AES polling mode. The registers used in AES polling mode are:

- AES Data RW Plaintext/Ciphertext 0 (AES_DATA_IN_0) registers, offset 0x060 to 0x06C
- AES Control (AES_CTRL) register, offset 0x050
- AES Hash Tag Out 0 (AES_TAG_OUT_0), offset 0x070

Figure 13-12. AES Polling Mode

AES Interrupt Mode

The application can use software interrupts to control the flow of Context In, Context Out, Data In, and Data Out requests. To enable these interrupts:

1. Once the device has been initialized, following the initialization sequences described in “Global Initialization” on page 1004 and “Initialization Subsequence” on page 1005, the application can enable the AES module interrupts through the **AES Interrupt Enable (AES_IRQENABLE)** register, offset 0x090. If all four interrupts must be enabled, the application can write 0x0000.000F to the **AES_IRQENABLE** register.
2. Load the input buffers, **AES_DATA_IN_n**, with data.

Note: If the application uses Interrupt Mode, an interrupt is generated for each block of processed data. To support larger data flow, AES μ DMA Mode should be used and the bits in the **AES_IRQENABLE** register should be cleared.

AES DMA Mode

When AES DMA Mode is enabled, the **AES_IRQENABLE** register should be cleared. To enable the μ DMA to transfer data follow these steps:

1. Once the AES module has been initialized, enable the AES module μ DMA channels by programming the **DMA Channel Map Select n (DMACHMAPn)** register in the μ DMA module. Further μ DMA configuration guidelines are available in the “Micro Direct Memory Access (μ DMA)” on page 708.
2. Configure the dma_done interrupts by programming the **AES DMA Masked Interrupt Status (AES_DMAMIS)** register, at CCM offset 0x028.
3. Enable the μ DMA channels in the AES by programming the μ DMA enable bits in the **AES System Configuration (AES_SYSCONFIG)** register, offset 0x084.
4. The input buffer registers, **AES_DATA_IN_n**, at offsets 0x060 to 0x06C, are loaded.

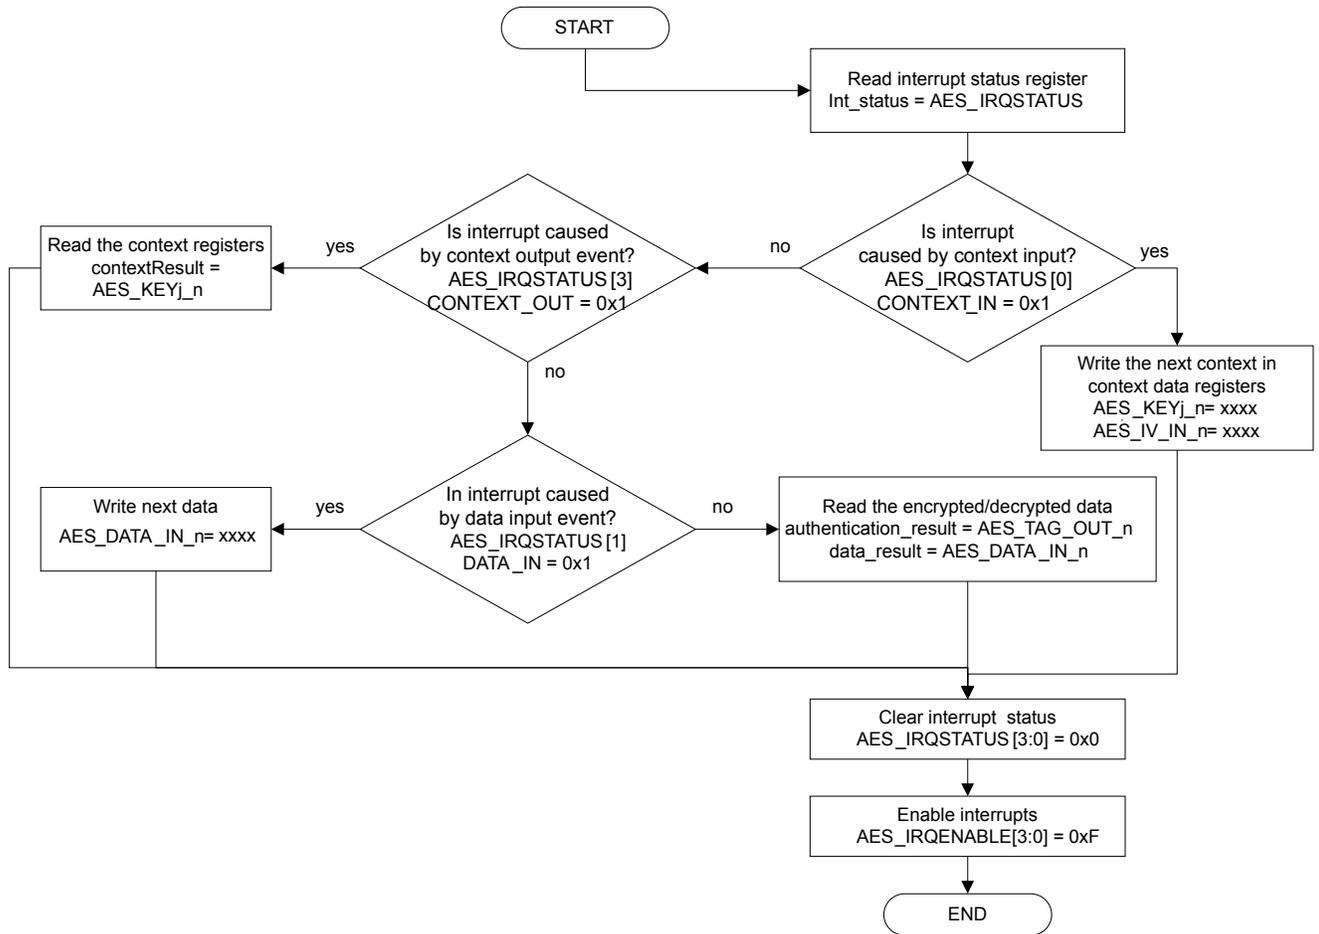

13.4.1.4 AES Events Servicing

Interrupt Servicing

This section describes the event servicing of the module. Figure 13-13 on page 1009 shows the AES interrupt service. The registers used during event servicing are:

- **AES_IRQSTATUS**
- **AES_KEY1_n**
- **AES_KEY2_n**
- **AES_IV_IN_n**
- **AES_DATA_IN_n**
- **AES_TAG_OUT_n**
- **AES_IRQENABLE**

Figure 13-13. AES Interrupt Service

13.5 Register Map

Table 13-5 on page 1009 lists the AES registers. The AES Module comprises registers that exist at an offset relative to the AES Module base address and a small set of AES μ DMA registers that exist at an offset relative to an Encryption Control Module base address. The AES Module register offsets are relative to the base address 0x4403.6000. The AES μ DMA interrupt registers are offset relative to the base address 0x4403.0000.

Table 13-5. AES Register Map

| Offset | Name | Type | Reset | Description | See page |
|---|------------|------|-------------|-------------|----------|
| AES Module Registers (AES Module Offset) | | | | | |
| 0x000 | AES_KEY2_6 | RW | 0x0000.0000 | AES Key 2_6 | 1012 |
| 0x004 | AES_KEY2_7 | RW | 0x0000.0000 | AES Key 2_7 | 1012 |
| 0x008 | AES_KEY2_4 | RW | 0x0000.0000 | AES Key 2_4 | 1012 |

Table 13-5. AES Register Map (continued)

13.6 AES Register Descriptions

This section lists and describes the AES registers, in numerical order by address offset.

- Register 1: AES Key 2_6 (AES_KEY2_6), offset 0x000**
Register 2: AES Key 2_7 (AES_KEY2_7), offset 0x004
Register 3: AES Key 2_4 (AES_KEY2_4), offset 0x008
Register 4: AES Key 2_5 (AES_KEY2_5), offset 0x00C
Register 5: AES Key 2_2 (AES_KEY2_2), offset 0x010
Register 6: AES Key 2_3 (AES_KEY2_3), offset 0x014
Register 7: AES Key 2_0 (AES_KEY2_0), offset 0x018
Register 8: AES Key 2_1 (AES_KEY2_1), offset 0x01C
Register 9: AES Key 1_6 (AES_KEY1_6), offset 0x020
Register 10: AES Key 1_7 (AES_KEY1_7), offset 0x024
Register 11: AES Key 1_4 (AES_KEY1_4), offset 0x028
Register 12: AES Key 1_5 (AES_KEY1_5), offset 0x02C
Register 13: AES Key 1_2 (AES_KEY1_2), offset 0x030
Register 14: AES Key 1_3 (AES_KEY1_3), offset 0x034
Register 15: AES Key 1_0 (AES_KEY1_0), offset 0x038
Register 16: AES Key 1_1 (AES_KEY1_1), offset 0x03C

This register contains the 32-bit key data for the AES module. This value can be expanded to 256-bits depending on the mode of operation. Table 13-6 on page 1012 describes the type of key that is held in register.

Note: Reads return zeros.

Table 13-6. AES Key Register Descriptions

| Register Name | Address Offset | Description |
|---------------|----------------|---|
| AES_KEY2_6 | 0x000 | Secure XTS second key / CBC-MAC third key |
| AES_KEY2_7 | 0x004 | Secure XTS second key (MSW for 256-bit key) / CBC-MAC third key (MSW) |
| AES_KEY2_4 | 0x008 | Secure XTS / CCM second key / CBC-MAC third key (LSW) |
| AES_KEY2_5 | 0x00C | Secure XTS second key (MSW for 192-bit key) / CBC-MAC third key |
| AES_KEY2_2 | 0x010 | Secure XTS / CCM / CBC-MAC second key / Hash Key input |
| AES_KEY2_3 | 0x014 | Secure XTS second key (MSW for 128-bit key) + CCM/CBC-MAC second key (MSW) / Hash Key input (MSW) |
| AES_KEY2_0 | 0x018 | Secure XTS / CCM / CBC-MAC second key (LSW) / Hash Key input (LSW) |
| AES_KEY2_1 | 0x01C | Secure XTS / CCM / CBC-MAC second key / Hash Key input |
| AES_KEY1_6 | 0x020 | Secure Key (LSW for 256-bit key) |
| AES_KEY1_7 | 0x024 | Secure Key (MSW for 256-bit key) |
| AES_KEY1_4 | 0x028 | Secure Key (LSW for 192-bit key) |
| AES_KEY1_5 | 0x02C | Secure Key (MSW for 192-bit key) |

Table 13-6. AES Key Register Descriptions (continued)

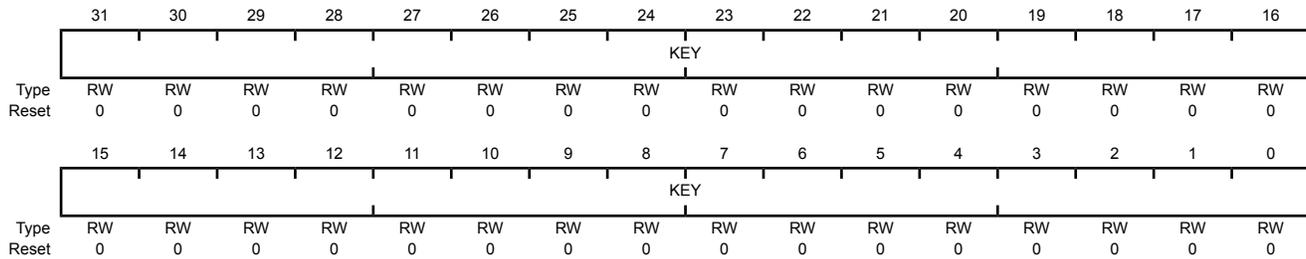

| Register Name | Address Offset | Description |
|---------------|----------------|----------------------------------|
| AES_KEY1_2 | 0x030 | Secure Key |
| AES_KEY1_3 | 0x034 | Secure Key (MSW for 128-bit key) |
| AES_KEY1_0 | 0x038 | Secure Key (LSW for 128-bit key) |
| AES_KEY1_1 | 0x03C | Secure Key |

AES Key (AES_KEYn_n)

Base 0x4403.6000

Offset 0x000

Type RW, reset 0x0000.0000

| Bit/Field | Name | Type | Reset | Description |
|-----------|------|------|------------|-------------|
| 31:0 | KEY | RW | 0x00000000 | Key Data |

This register contains the 32-bit key data for the AES module.

Register 17: AES Initialization Vector Input 0 (AES_IV_IN_0), offset 0x040

Register 18: AES Initialization Vector Input 1 (AES_IV_IN_1), offset 0x044

Register 19: AES Initialization Vector Input 2 (AES_IV_IN_2), offset 0x048

Register 20: AES Initialization Vector Input 3 (AES_IV_IN_3), offset 0x04C

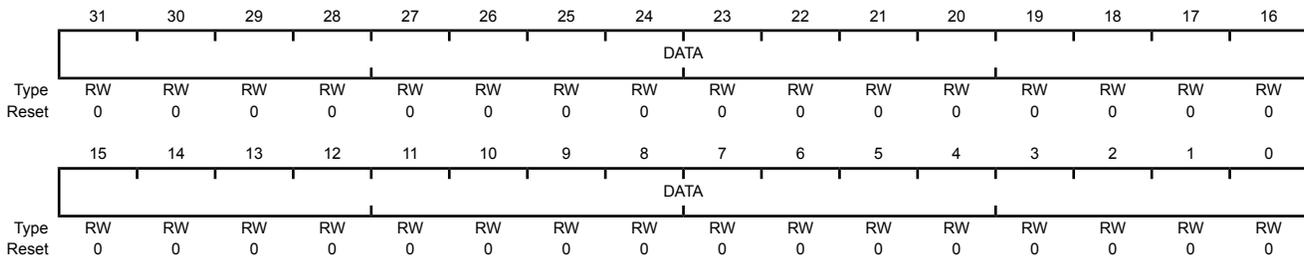

This register contains the initialization vector input.

AES Initialization Vector Input (AES_IV_IN_n)

Base 0x4403.6000

Offset 0x040

Type RW, reset 0x0000.0000

| Bit/Field | Name | Type | Reset | Description |
|-----------|------|------|-------------|--|
| 31:0 | DATA | RW | 0x0000.0000 | Initialization Vector Input This field contains the initialization input vector. The least significant word (LSW) is represented in register AES_IV_IN_0 and the most significant word is stored in AES_IV_IN_3 |

Register 21: AES Control (AES_CTRL), offset 0x050

This register determines the mode of operation of the AES Engine.

AES Control (AES_CTRL)

Base 0x4403.6000
Offset 0x050
Type RW, reset 0x8000.0000

| | | | | | | | | | | | | | | | | |

| Bit/Field | Name | Type | Reset | Description |
|-----------|--------------|------|-------|---|
| 31 | CTXTRDY | RO | 1 | Context Data Registers Ready |
| | | | | Value Description |
| | | | | 0 The context data registers are not ready to be overwritten. |
| | | | | 1 The context data registers can be overwritten and the host is permitted to write the next context. |
| 30 | SVCTXTRDY | RO | 0 | AES TAG/IV Block(s) Ready |
| | | | | Note: This bit is only asserted if the SAVE_CONTEXT bit is set to 1. This bit is mutual exclusive with the CTXTRDY bit. |
| | | | | Value Description |
| | | | | 0 AES authentication TAG and/or IV block(s) is/are not available. |
| | | | | 1 Indicates the AES authentication TAG and /or IV block(s) is/are available for the host to retrieve. |
| 29 | SAVE_CONTEXT | RW | 0 | TAG or Result IV Save |
| | | | | If this bit is set, the CONTEXT_OUT interrupt bit is set in the AES_IRQSTATUS register if the operation is finished and related signals are enabled. |
| | | | | Value Description |
| | | | | 0 No effect. |
| | | | | 1 Indicates an authentication TAG of result IV needs to be stored as a result context. |

| Bit/Field | Name | Type | Reset | Description | | | | | | | | | | | | | | |
|-----------|--|------|-------|---|-------|-------------|-----|------------------------------|-----|--|-----|--|-----|--|-----------|----------|-----|-----------|
| 28:25 | reserved | R | 0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. | | | | | | | | | | | | | | |
| 24:22 | CCM_M | RW | 0 | <p>Counter with CBC-MAC (CCM)</p> <p>Defines M which indicates the length of the authentication field for CCM operations; the authentication field length equals two times the sum of CCM-M plus one.</p> <p>Note: The AES Engine always returns a 128-bit authentication field, of which the M least significant bytes are valid. All values are supported.</p> | | | | | | | | | | | | | | |
| 21:19 | CCM_L | RW | 0 | <p>L Value</p> <p>Defines L, which indicates the width of the length field for CCM operations; the length field in bytes equals the value of CMM-L plus one. Supported values for L are:</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>width = 0</td> </tr> <tr> <td>0x1</td> <td>width = 2</td> </tr> <tr> <td>0x2</td> <td>reserved</td> </tr> <tr> <td>0x3</td> <td>width = 4</td> </tr> <tr> <td>0x4 - 0x6</td> <td>reserved</td> </tr> <tr> <td>0x7</td> <td>width = 8</td> </tr> </tbody> </table> | Value | Description | 0x0 | width = 0 | 0x1 | width = 2 | 0x2 | reserved | 0x3 | width = 4 | 0x4 - 0x6 | reserved | 0x7 | width = 8 |
| Value | Description | | | | | | | | | | | | | | | | | |
| 0x0 | width = 0 | | | | | | | | | | | | | | | | | |

| 0 | OUTPUT_READY | RO | 0 | Output Ready Status |
| | | | | Value Description |
| | | | | 0 No AES output block is available. |
| | | | | 1 An AES output block is available for the host to retrieve. |

Register 22: AES Crypto Data Length 0 (AES_C_LENGTH_0), offset 0x054

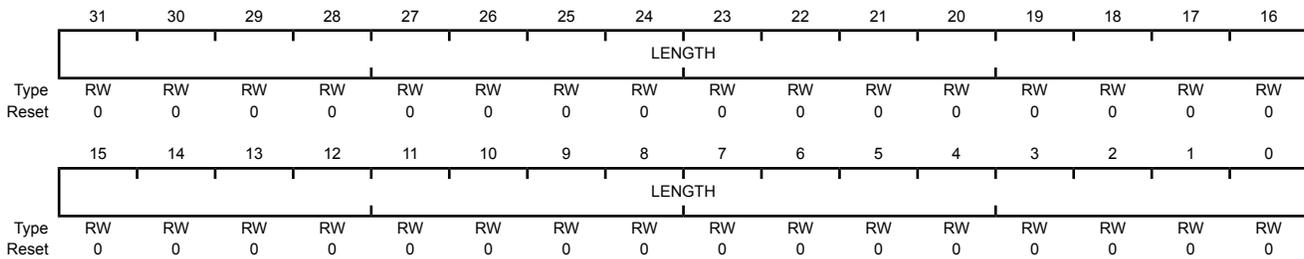

Register 23: AES Crypto Data Length 1 (AES_C_LENGTH_1), offset 0x058

AES Crypto Data Length n (AES_C_LENGTH_n) registers (LSW and MSW) store the cryptographic data length in bytes for all modes. The **AES_C_LENGTH_0** register stores the most significant word and the **AES_C_LENGTH_1** register stores the least significant word. Once processing with this context is started, this length decrements to zero. Data lengths up to $(2^{61} - 1)$ bytes are allowed. For GCM, any value up to 236 - 32 bytes can be used. This is because a 32-bit counter mode is used; the maximum number of 128-bit blocks is $2^{32} - 2$, resulting in a maximum number of bytes of $2^{36} - 32$. A write to this register triggers the engine to start using this context. This is valid for all modes except GCM and CCM. Note that for the combined modes, this length does not include the authentication only data; the authentication length is specified in the **AES_AUTH_LENGTH** register below. All modes must have a length greater than 0. For the combined modes, it is permissible to have one of the lengths equal to zero. For the basic encryption modes (ECB/CBC/CTR/ICM/CFB128) it is permissible to program zero to the length field; in that case the length is assumed infinite. All data must be byte (8-bit) aligned; bit aligned data streams are not supported by the AES Engine.

Note: For a Host read operation, these registers return all zeroes.

AES Crypto Data Length (AES_C_LENGTH_n)

Base 0x4403.6000
 Offset 0x054
 Type RW, reset 0x0000.0000

| Bit/Field | Name | Type | Reset | Description |
|-----------|--------|------|------------|--|
| 31:0 | LENGTH | RW | 0x00000000 | Data Length This field stores the cryptographic data length in bytes for all modes. |

Register 24: AES Authentication Data Length (AES_AUTH_LENGTH), offset 0x05C

The **AES Authentication Data Length (AES_AUTH_LENGTH)** register stores the authentication data length in bytes for combined modes only (GCM or CCM). Supported `AUTH` lengths for CCM are from 0 to $(2^{16} - 28)$ bytes. For GCM any value up to $(2^{32} - 1)$ bytes can be used. Once processing with this context is started, this length decrements to zero. A write to this register triggers the engine to start using this context for GCM and CCM. For XTS, this register is optionally used to load `j`. Loading of `j` is only required if `j` \neq 0. `j` is a 28-bit value and must be written to bits [31-4] of this register. `j` represents the sequential number of the 128-bit block inside the data unit. For the first block in a unit, this value is zero. It is not required to provide a `j` for each new data block within a unit. Note that it is possible to start with a `j` unequal to zero.

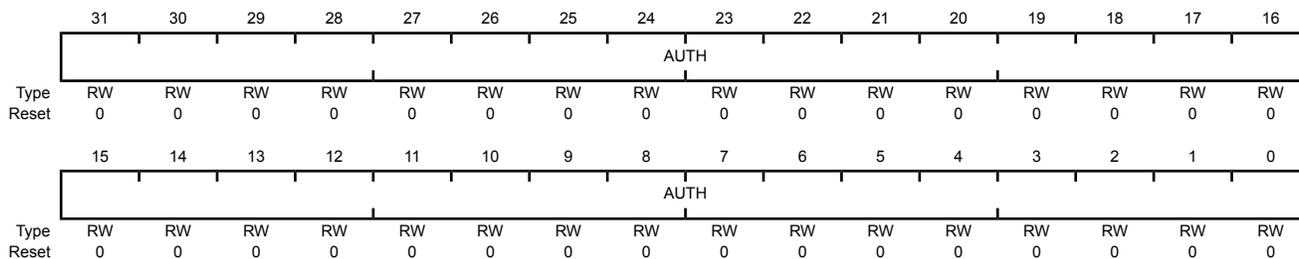

Note: For a Host read operation, these registers return all-zeroes..

AES Authentication Data Length (AES_AUTH_LENGTH)

Base 0x4403.6000

Offset 0x05C

Type RW, reset 0x0000.0000

| Bit/Field | Name | Type | Reset | Description |
|-----------|------|------|------------|--|
| 31:0 | AUTH | RW | 0x00000000 | Authentication Data Length This field stores the authentication data length in bytes for combined modes (GCM or CCM). |

Register 25: AES Data RW Plaintext/Ciphertext 0 (AES_DATA_IN_0), offset 0x060

Register 26: AES Data RW Plaintext/Ciphertext 1 (AES_DATA_IN_1), offset 0x064

Register 27: AES Data RW Plaintext/Ciphertext 2 (AES_DATA_IN_2), offset 0x068

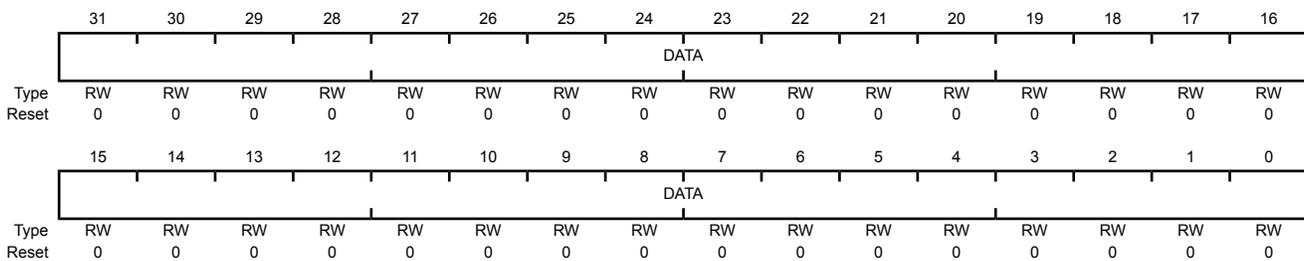

Register 28: AES Data RW Plaintext/Ciphertext 3 (AES_DATA_IN_3), offset 0x06C

The **AES Data RW Plaintext/Ciphertext n (AES_DATA_IN_n)** registers are used to read and write plaintext/ciphertext. The **AES_DATA_IN_0** register contains the most significant word; the **AES_DATA_IN_3** register contains least significant word.

Note: The **AES_DATA_IN_0** register acts as a FIFO and shifts data into the other **AES_DATA_IN_n** registers.

AES Data RW Plaintext/Ciphertext (AES_DATA_IN_n)

Base 0x4403.6000
 Offset 0x060
 Type RW, reset 0x0000.0000

| Bit/Field | Name | Type | Reset | Description |
|-----------|------|------|------------|--|
| 31:0 | DATA | RW | 0x00000000 | Secure Data RW Plaintext/Ciphertext This field holds the plaintext/ciphertext data. |

Register 29: AES Hash Tag Out 0 (AES_TAG_OUT_0), offset 0x070

Register 30: AES Hash Tag Out 1 (AES_TAG_OUT_1), offset 0x074

Register 31: AES Hash Tag Out 2 (AES_TAG_OUT_2), offset 0x078

Register 32: AES Hash Tag Out 3 (AES_TAG_OUT_3), offset 0x07C

This register displays the Hash result. The **AES_TAG_OUT_0** register is the most significant word of the Hash and the **AES_TAG_OUT_3** register is the least significant word.

AES Hash Tag Out (AES_TAG_OUT_n)

Base 0x4403.6000

Offset 0x070

| | | | | 0 The context in interrupt is not active. |
| | | | | 1 The context in interrupt is active and the interrupt output has been triggered. |

Register 37: AES Interrupt Enable (AES_IRQENABLE), offset 0x090

This register contains an enable bit for each unique interrupt generated by the module. It matches the layout of **AES_IRQSTATUS** register. An interrupt is enabled when the bit in this register is set to 1. An interrupt that is enabled is propagated to the NVIC controller. All AES software interrupts need to be enabled explicitly by writing this register.

Note: If the application uses Interrupt Mode, an interrupt is generated for each block of processed data. To support larger data flow, AES μ DMA Mode should be used and the bits in the **AES_IRQENABLE** register should be cleared.

14 Data Encryption Standard Accelerator (DES)

The DES module provides hardware accelerated data encryption and decryption functions. The module runs either the single DES or the triple DES (3DES) algorithm in compliance with the [FIPS 46-3 standard](#) and supports electronic codebook (ECB), cipher block chaining (CBC), and cipher feedback (CFB) modes of operation. It does not support the output feedback (OFB) mode of operation in hardware.

The purpose of the DES algorithm is to encrypt (encipher) or decrypt (decipher) binary coded information. Encrypting data converts it to an unintelligible form called cipher text. Decrypting cipher text converts the data back to its original form called plaintext. DES is a symmetrical algorithm in that the encryption and decryption keys are identical. Each triple DES encrypt/decrypt operation is a compound of DES encrypt and decrypt operations.

The DES accelerator includes the following main features:

- DES/3DES encryption and decryption.
- Feedback modes: ECB, CBC, CFB
- Host interrupt or μ DMA driven modes of operation. μ DMA support for data and context in/result out
- Fully synchronous design
- Internal wide-bus interface

14.1 DES Functional Description

The DES module is an efficient implementation of a DES block cipher. Block ciphers, as opposed to stream ciphers, operate on blocks of plain text and cipher text. The DES block size is 8-byte. The DES key consists of 64 binary digits, but only 56 bits are actually used directly by the algorithm. The other 8 bits are used for error detection.

The 64-bit block of input data to be enciphered is initially permuted, then passed through 16 iterations of a calculation that uses a cipher function and finally permuted to the inverse of the initial permutation. At each of the 16 iterations, a 48-bit key computed from the 64-bit input key is applied to one of the 32-bit sub-blocks of the 64-bit input block using the cipher function. The 48-bit key value changes for each iteration. The result of the cipher function is a 32-bit sub-block, which is concatenated with the second 32-bit input sub-block. The resulting 64-bit output block of each iteration feeds back as the input of the next iteration. To decipher, it is only necessary to apply the same algorithm to the enciphered message block, taking care that each iteration of the computation will use the same 48-bit key which was used during enciphering.

The triple DES is the DES used three times in a row (also known as DES-EDE). It uses three keys key1, key2, and key3, so that key length is 168 bits effective: a 64-bit block plaintext is encrypted with key1, decrypted with key2, and encrypted with key3, and a 64-bit ciphertext is decrypted with key1, encrypted with key2, and decrypted with key3.

There are three keying options defined in ANSI X9.52 for DES-EDE:

- The three keys key1, key2, and key3 are independent.
- key1 and key2 are independent, but key1 = key3
- key1 = key2 = key3

The first option provides highest level of security; the last option is compatible with single DES. See Table 14-1 on page 1041 for key use.

Table 14-1. Key Repartition

| Mode | Key1_L | Key1_H | Key2_L | Key2_H | Key3_L | Key3_H |
|----------------|--------|--------|--------|--------|--------|--------|
| 64-bit (DES) | √ | √ | X | X | X | X |
| 192-bit (3DES) | √ | √ | √ | √ | √ | √ |

ECB, CBC, and CFB modes can be used with DES and 3DES modes.

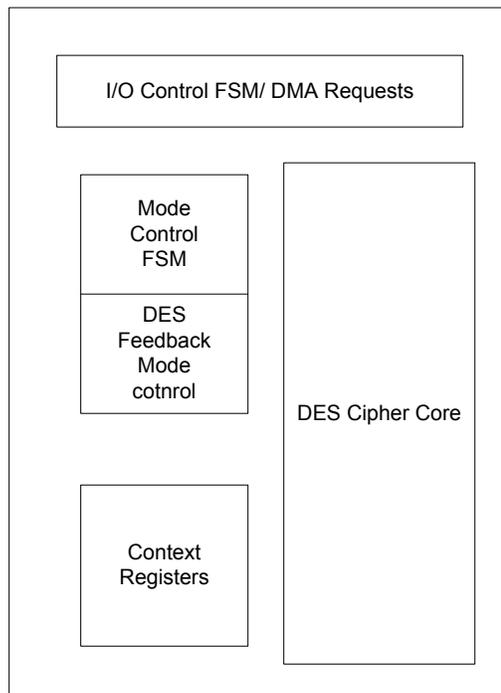

14.2 DES Block Diagram

The module architecture consists of primary blocks, as shown in Figure 14-1 on page 1041. The DES module includes a register interface, and a μ DMA and interrupt interface.

Depending of the availability of context and data, the DES engine is automatically triggered to process the data. The DES engine is directly connected to the context and data registers such that it can immediately start processing when all data is available.

Packets (blocks of 64 bits) must be parsed into blocks and sequentially fed into the DES, which can buffer the block currently being processed as well as an additional block that may be queued in advance.

Figure 14-1. DES Block Diagram

14.2.1 μ DMA Control

The μ DMA and interrupt request logic is controlled by the DES Engine. The DES Engine can have multiple μ DMA request signals active in parallel.

There are three DMA channels available:

- DMA context in - Request a new context (DES0 Cin)
- DMA data in - Request input data (DES0 Din)
- DMA data out - Request output data read (DES0 Dout)

14.2.2 Interrupt Control

There is one interrupt for the DES that is sent to the interrupt controller. This interrupt is an OR of the enabled interrupt bits in the **DES Interrupt Status (DES_IRQSTATUS)** register. These bits are enabled through the **DES Interrupt Enable (DES_IRQENABLE)** register. The following events can generate an interrupt bit to be set in the **DES_IRQSTATUS** register. These are:

- New context input required
- Data input required
- Data output ready

14.2.3 Register Interface

The Register Interface block performs all address decoding and control; however, not all registers are available in this block. The context and data input registers are in the DES engine.

14.2.4 DES Engine

The DES buffered engine consists of the following major functional blocks:

- Cipher core: the DES algorithm
- Mode control FSM: manages the data flow to and from the DES buffered engine and starts each encrypt/decrypt operation
- DES feedback mode block: the logic that implements the various feedback modes supported by the DES buffered engine

14.2.4.1 Mode Control FSM

The Mode control FSM manages the data flow to and from the DES engine. This block also sends a start pulse to the encrypt/decrypt core and triggers the core to use the new mode keys when a new context is needed. This module also controls the 3DES operation, such that the DES core module is triggered three times (with different keys) before the result data becomes available.

14.2.4.2 DES Feedback Mode Block

The DES feedback mode block buffers the input and output blocks and contains all logic to implement the 3DES and various feedback modes. See the FIPS-81 document for details on the ECB, CBC, and CFB modes of operation.

By itself, the DES cipher core outputs data compliant for ECB encryption. However, most applications use DES with feedback. Feedback provides additional security by randomizing repeated patterns in the plain text, which could otherwise be exploited to attack the cipher text. The DES buffered engine supports ECB, CBC, and CFB modes of operations for the DES and 3DES algorithm.

3DES mode performs the DES algorithm three times on a single block and uses a different key for each invocation of the DES algorithm, greatly increasing security of the cipher text but at the cost

of a 3x reduction in throughput. The DES buffered engine implements a 3DES logic wrapper around the 2-round DES core, enabling seamless 3DES encryption.

14.2.4.3 DES Cipher Core

The DES cipher core implements the DES algorithm as specified in the FIPS 46-3. The core operates on the input block and performs the required substitution, shift, and mix operations. The core also applies the correct key-scheduling.

Inherently, considerable parallelism is possible with the DES algorithm. This is exploited in two ways. For high performance, the 64 bits composing the data block are processed concurrently (4-round implementation). For low gate-count, resources are shared on both the main data and key paths (1-round implementation).

A fundamental component of the DES algorithm is the substitution box (S-Box). The S-Box provides a unique 4-bit output for each 6-bit input. The S-Box design is a primary factor for both performance and gate count. The DES Cipher Core has a standard lookup table S-Box that allows room for the synthesizer to optimize on timing or gate count.

14.3 Software Reset

Table 14-2 on page 1043 lists the resets used in the DES module.

Table 14-2. DES Reset Description

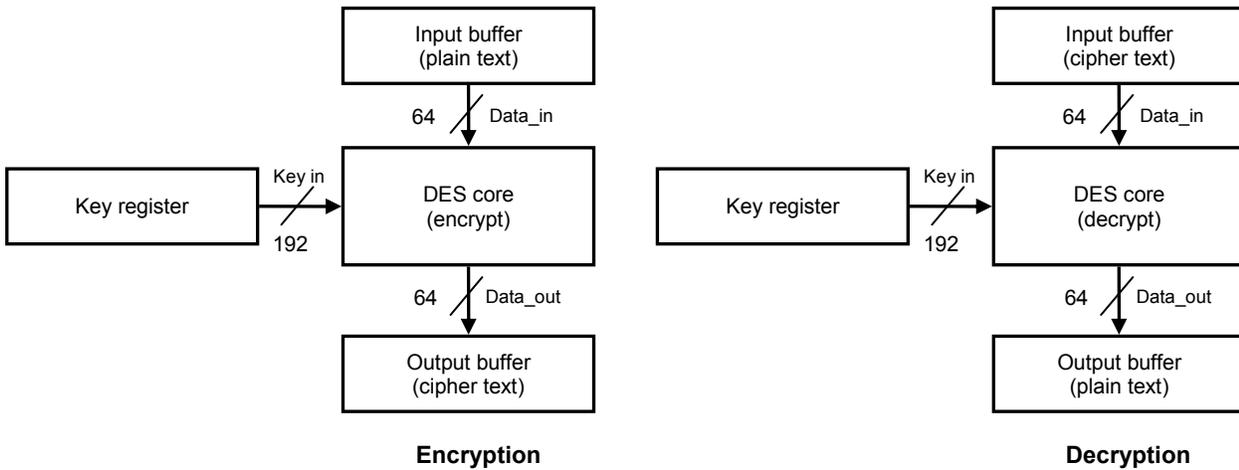

| Type | Name | Source | Description |
|----------|--------------------------------|----------|---|
| Hardware | DES_RST | PRCM | Global reset |
| Software | DES_SYSCONFIG [1] SOFTRESET | Internal | Starts the soft reset sequence. When the DES_SYSSTATUS/DES_P_SYSSTATUS[0] RESETDONE bit goes to 1, the soft reset sequence is finished. |

14.4 DES Supported Modes of Operation

14.4.1 ECB Feedback Mode

Figure 14-2 on page 1044 shows the basic ECB feedback mode of operation, where the input data is passed directly to the basic cryptographic core and the output of the cryptographic core is passed directly to the output buffer. For decryption the DES core operates in reverse, this means the decrypt key sequence is used for the data processing, where encryption uses the encrypt key sequence.

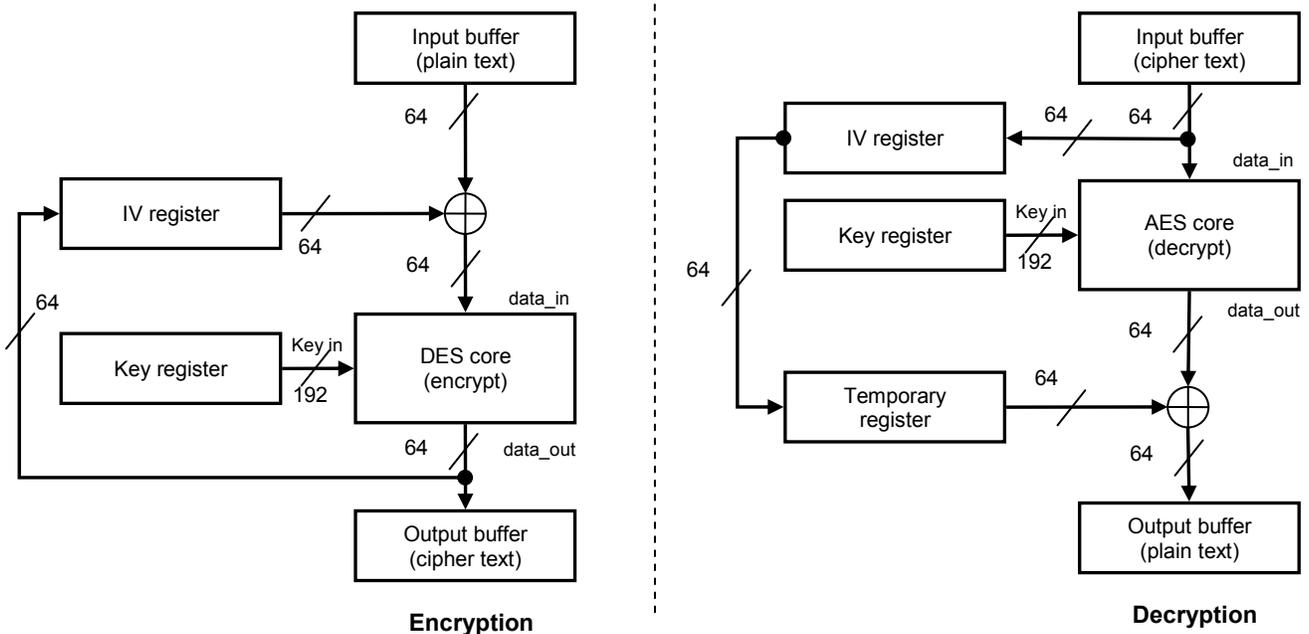

Figure 14-2. DES - ECB Feedback Mode

14.4.1.1 CBC Feedback Mode

Figure 14-3 on page 1044 shows the CBC feedback mode of operation, where the input data is XORed with the initialization vector (IV) before it is passed to the basic crypto core. The output of the crypto core is passed directly to the output buffer. For decryption the operation is reversed, resulting in an XOR at the output of the crypto core.

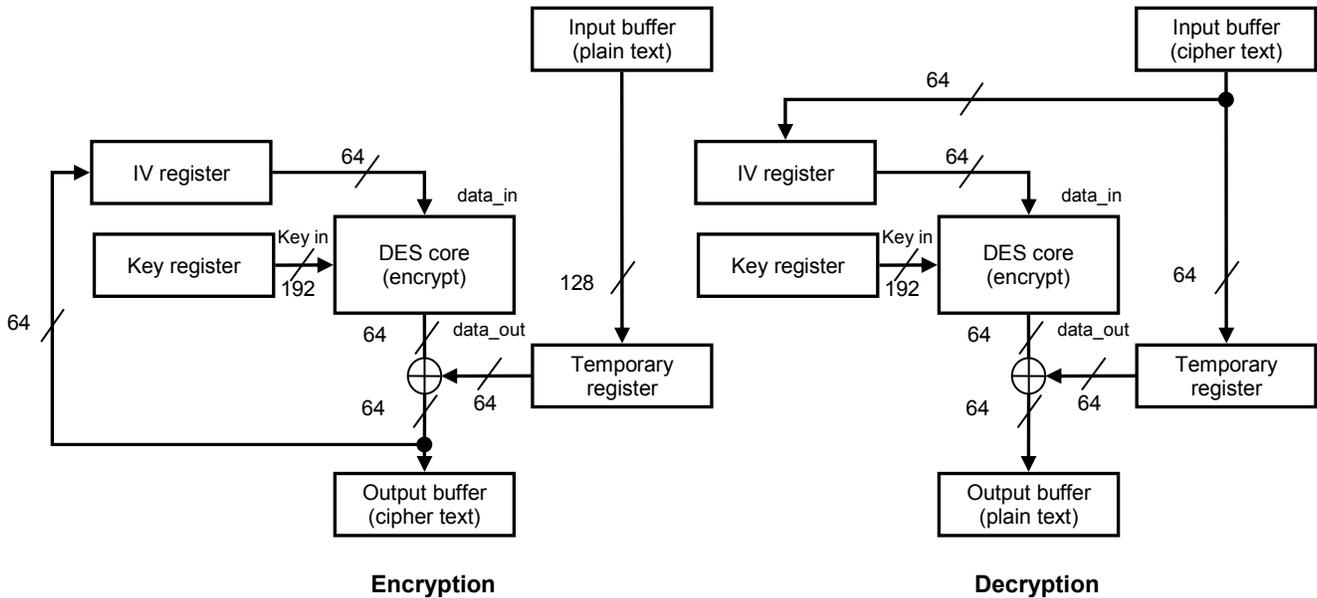

Figure 14-3. DES3DES - CBC Feedback Mode

14.4.1.2 CFB Feedback Mode

Figure 14-4 on page 1045 shows the CFB mode of operation for encryption and decryption. The input for the crypto core is the IV; the result is XORed with the data. The result is fed back via the IV register, as the next input for the crypto core. The decrypt operation is reversed, but the crypto core is still performing an encryption.

Figure 14-4. DES3DES-CFB Feedback Mode

14.5 DES Module Programming Guide -Low Level Programming Models

14.5.1 Surrounding Modules Global Initialization

14.5.1.1 Main Sequence - DES Global Initialization

This procedure initializes the DES after a POR.

Table 14-3. DES Global Initialization

| Step | Register/Bit Field/Programming Model | Value |
|--|--------------------------------------|-------|
| Execute software reset. | DES_SYSCONFIG[1] SOFTRESET | 0x1 |
| Wait for reset to complete | DES_SYSSTATUS[0] RESETDONE | = 0x1 |
| Select force idle mode | DES_SYSCONFIG[3:2] SIDLE | 0x0 |
| Select the algorithm type (DES or 3DES) | See the programming models | |
| Select the operating mode (ECB, CBC or CFB). | DES_CTRL[5:4] MODE | - |
| IF: ECB operating mode not selected. | DES_CTRL[5:4] MODE | ≠ 0x0 |
| Load the initialization vector LSW. | DES_IV_L[31:0] IV_L | - |

| Define the cryptographic data length. | DES_LENGTH[31:0] LENGTH | - |
| ENDIF | | |
| Select encryption or decryption. | DES_CTRL[2] DIRECTION | - |

14.5.1.2 Subsequence - Configure the DES Algorithm Type

This subsequence details the DES algorithm type settings.

Table 14-4. DES Algorithm Type Configuration

| Step | Register/Bit Field/Programming Model | Value |
|-----------------------|--------------------------------------|-------|
| Load key 1 LSW. | DES_KEY1_L[31:0] KEY1_L | - |
| Load key 1 MSW. | DES_KEY1_H[31:0] KEY1_H | - |
| Select DES algorithm. | DES_CTRL[3] TDES | 0x0 |

14.5.1.3 Subsequence - Configure the 3DES Algorithm Type

This subsequence details the 3DES algorithm type settings.

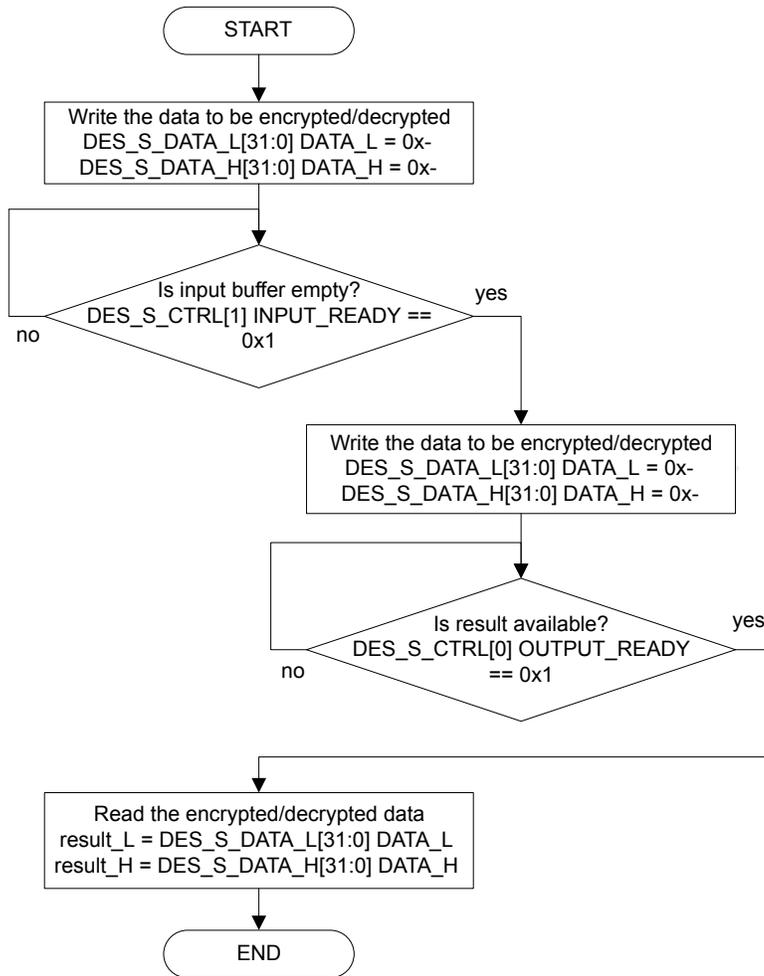

Table 14-5. 3DES Algorithm Type Configuration

| Step | Register/Bit Field/Programming Model | Value |
|------------------------|--------------------------------------|-------|
| Load key 1 LSW. | DES_KEY1_L[31:0] KEY1_L | - |
| Load key 1 MSW. | DES_KEY1_H[31:0] KEY1_H | - |
| Load key 2 LSW. | DES_KEY2_L[31:0] KEY2_L | - |
| Load key 2 MSW. | DES_KEY2_H[31:0] KEY2_H | - |
| Load key 3 LSW. | DES_KEY3_L[31:0] KEY3_L | - |
| Load key 3 MSW. | DES_KEY3_H[31:0] KEY3_H | - |
| Select 3DES algorithm. | DES_CTRL[3] TDES | 0x1 |

14.5.2 Operational Modes Configuration

14.5.2.1 Main Sequence - DES Polling Mode

Figure 14-5 on page 1047 shows DES polling mode. The registers used in DES polling mode are: DES_DATA_L, DES_DATA_H, and DES_CTRL.

Figure 14-5. DES Polling Mode

14.5.2.2 DES Interrupt Mode

Table 14-6 on page 1047 lists the DES interrupt mode steps.

Table 14-6. DES Interrupt Mode

| Step | Register/Bit Field/Programming Model | Value |
|--|--------------------------------------|-------|
| Enable DES module interrupts. | DES_IRQENABLE[2:0] | 0x7 |
| Load the input buffer data LSW register. | DES_DATA_L[31:0] DATA_L | - |
| Load the input buffer data HSW register. | DES_DATA_H[31:0] DATA_H | - |

14.5.2.3 DES Interrupt DMA Mode

Table 14-7 on page 1047 lists the DES DMA mode steps.

Table 14-7. DES DMA Mode

| Step | Register/Bit Field/Programming Model | Value |
|--|--------------------------------------|-------|
| Enable DES module DMA requests. | DES_SYSCONFIG[7:5] | 0x7 |
| Load the input buffer data LSW register. | DES_DATA_L[31:0] DATA_L | - |

Table 14-7. DES DMA Mode (continued)

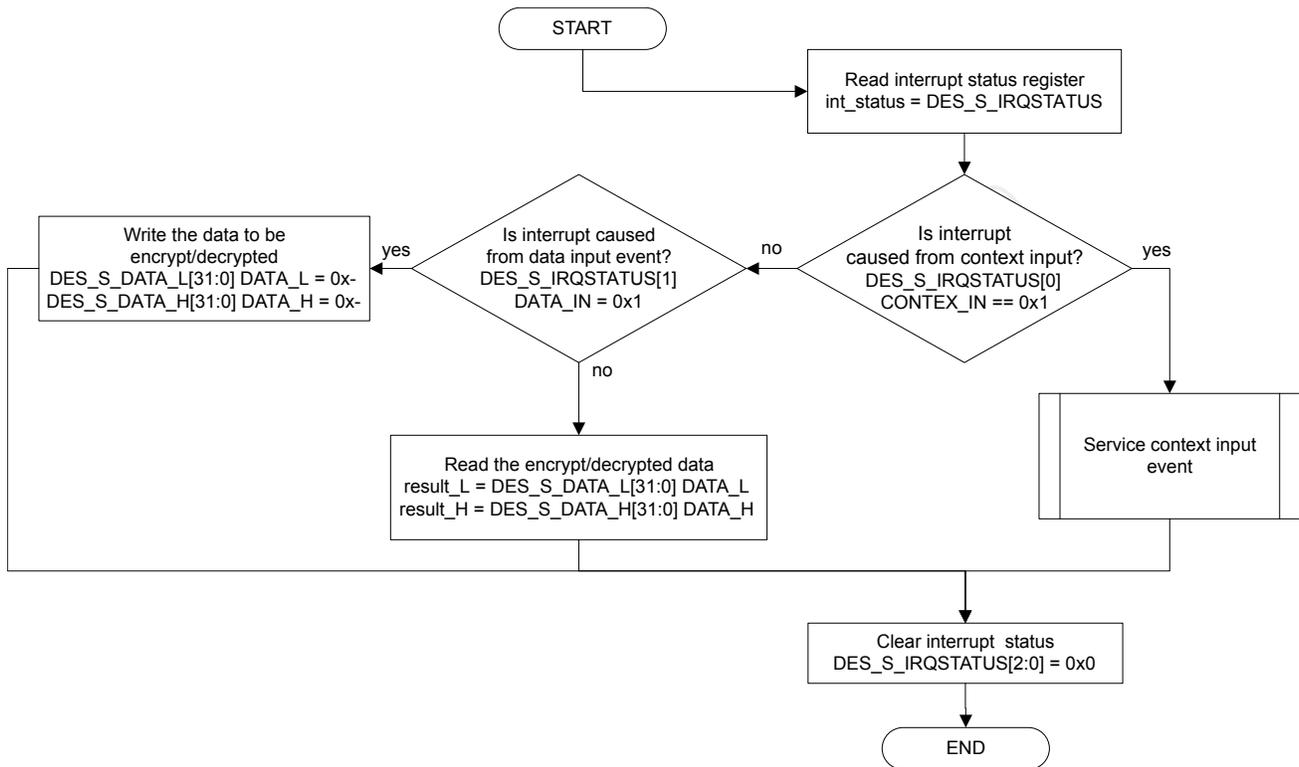

| Step | Register/Bit Field/Programming Model | Value |
|--|--------------------------------------|-------|
| Load the input buffer data HSW register. | DES_DATA_H[31:0] DATA_H | - |

14.5.3 DES Events Servicing

14.5.3.1 Interrupt Servicing

This section describes the event servicing of the module. Figure 14-6 on page 1048 shows the DES interrupt service. The registers used during event servicing are: DES_IRQSTATUS, DES_DATA_L, and DES_DATA_H.

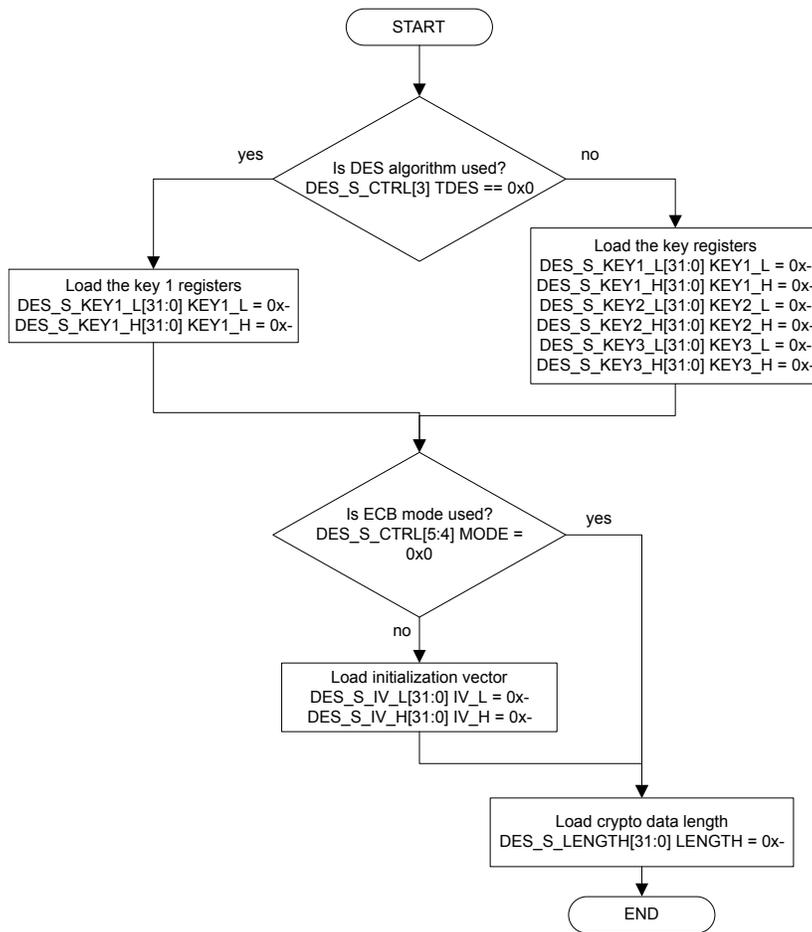

Figure 14-6. DES Interrupt Service

14.5.3.2 Context Input Event Servicing

This section describes the context input event servicing of the module, as shown in Figure 14-7 on page 1049. The registers used during event servicing are: DES_CTRL, DES_SYSCONFIG, DES_KEY1_L, DES_KEY1_H, DES_KEY2_L, DES_KEY2_H, DES_KEY3_L, DES_KEY3_H, DES_IV_L, DES_IV_H, and DES_LENGTH.

Figure 14-7. DES Context Input Event Service

14.6 Register Map

Table 14-8 on page 1049 lists the DES registers. The DES Module comprises registers that exist at an offset relative to the DES Module base address and a small set of DES μ DMA registers that exist at an offset relative to an Encryption Control Module base address. The DES Module register offsets are relative to the base address 0x4403.8000. The Encryption Control register offsets are relative to the base address 0x4403.0000.

Note: The DES registers are limited to 32-bit data accesses; 8- and 16-bit accesses are not allowed and can corrupt register contents.

Table 14-8. DES Register Map

| Offset | Name | Type | Reset | Description | See page |
|---|------------|------|-------------|-------------------------------|----------|
| DES Module Registers (DES Module Offset) | | | | | |
| 0x000 | DES_KEY3_L | RW | 0x0000.0000 | DES Key 3 LSW for 192-Bit Key | 1051 |

14.7 DES Register Description

This section lists and describes the DES registers, in numerical order by address offset.

Register 1: DES Key 3 LSW for 192-Bit Key (DES_KEY3_L), offset 0x000

Register 2: DES Key 3 MSW for 192-Bit Key (DES_KEY3_H), offset 0x004

Register 3: DES Key 2 LSW for 128-Bit Key (DES_KEY2_L), offset 0x008

Register 4: DES Key 2 MSW for 128-Bit Key (DES_KEY2_H), offset 0x00C

Register 5: DES Key 1 LSW for 64-Bit Key (DES_KEY1_L), offset 0x010

Register 6: DES Key 1 MSW for 64-Bit Key (DES_KEY1_H), offset 0x014

The function of each of these registers is described in more detail in Table 14-9 on page 1051.

Note: A read of this register returns all zeros.

Table 14-9. DES Key Register Mapping

| Register Name | Address Offset | Description |
|---------------|----------------|---------------------------------------|
| DES_KEY3_L | 0x00000000 | KEY3 (LSW) for 192-bit key |
| DES_KEY3_H | 0x00000004 | KEY3 (MSW) for 192-bit key |
| DES_KEY2_L | 0x00000008 | KEY2 (LSW) for 192-bit key |
| DES_KEY2_H | 0x0000000C | KEY2 (MSW) for 192-bit key |
| DES_KEY1_L | 0x00000010 | KEY1 (LSW) for 64-bit key/192-bit key |
| DES_KEY1_H | 0x00000014 | KEY1 (MSW) for 64-bit key/192-bit key |

DES Key for 192-Bit Key (DES_KEYn_n)

| 0 | OUTPUT_READY | R | 0 | When 1, Data decrypted/encrypted ready |

Register 10: DES Cryptographic Data Length (DES_LENGTH), offset 0x024

Indicates the cryptographic data length in bytes for all modes. Once processing is started with this context, this length decrements to zero. Data lengths up to (232 - 1) bytes are allowed. A write to this register triggers the engine to start using this context.

Note: A read of this register returns all zeros.

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|------------|---|
| 31:3 | reserved | RO | 0x0000.000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 2 | DOUT | RW | 0 | Data Out DMA Done Interrupt Mask If this bit is unmasked, an interrupt is generated when the μ DMA writes the last word of the process result. Value Description 0 The DOUT interrupt is suppressed and not sent to the interrupt controller. 1 The DOUT interrupt is sent to the interrupt controller. |
| 1 | DIN | RW | 0 | Data In DMA Done Interrupt Mask If this bit is unmasked, an interrupt is generated when the μ DMA writes the last word of input data to the internal FIFO of the engine. Value Description 0 The DIN interrupt is suppressed and not sent to the interrupt controller. 1 The DIN interrupt is sent to the interrupt controller. |
| 0 | CIN | RW | 0 | Context In DMA Done Interrupt Mask If this bit is unmasked, an interrupt is generated when the μ DMA completes a context write to the internal register. Value Description 0 The CIN interrupt is suppressed and not sent to the interrupt controller. 1 The CIN interrupt is sent to the interrupt controller. |

Register 20: DES DMA Raw Interrupt Status (DES_DMARIS), offset 0x034

The **DES DMA Raw Interrupt Status** register contains the raw interrupt status. If any of these bits read 1, the processor is interrupted if the corresponding masked interrupt status bit is set to 1.

15 SHA/MD5 Accelerator

The SHA/MD5 module provides hardware-accelerated hash functions and can run:

- MD5 message digest algorithm developed by Ron Rivest in 1991
- SHA-1 algorithm compliant with the [FIPS 180-3 standard](#)
- SHA-2 (SHA-224 and SHA-256) algorithm compliant with the FIPS 180-3 standard
- Hash message authentication code (HMAC) operation

The algorithms produce a condensed representation of a message or a data file, called digest or signature, which can then be used to verify the message integrity.

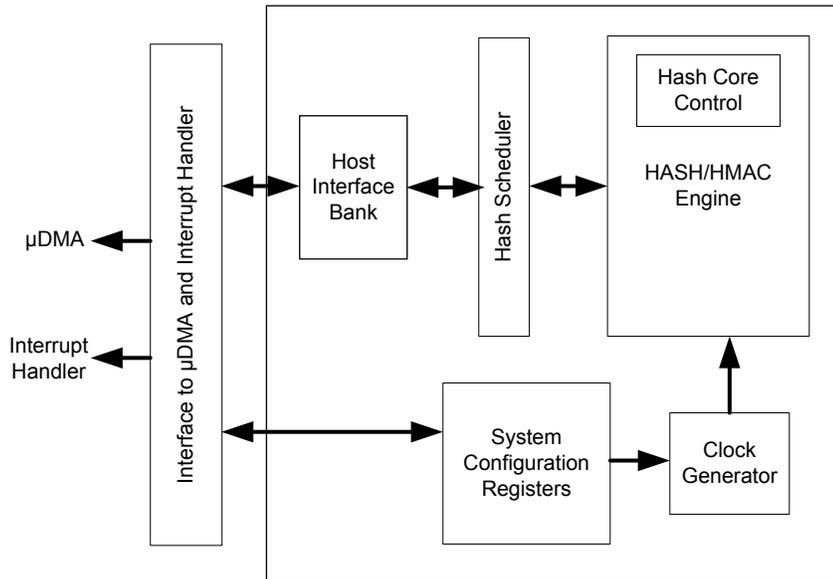

- Hashing of 0 to $2^{33} - 2$ bytes of data (of which $2^{32} - 1$ bytes are in one pass) using the MD5, SHA-1, SHA-224, or SHA-256 hash algorithm (byte granularity only, no support for bit granularity)
- Automatic HMAC key preprocessing for HMAC keys up to 64 bytes
- Host-assisted HMAC key preprocessing for HMAC keys larger than 64 bytes
- HMAC from precomputes (inner/outer digest) for improved performance on small blocks
- Supports μ DMA operation for data and context in/result out transfers
- Supports interrupt to read the digest (signature)

15.1 SHA/MD5 Functional Description

15.1.1 SHA/MD5 Block Diagram

Figure 15-1 on page 1070 shows the module architecture, which consists of four primary blocks: the Hash/HMAC engine, the configuration registers and the interface to μ DMA and the interrupt handler.

Figure 15-1. SHA/MD5 Module Block Diagram

15.1.1.1 Configuration Registers

The configuration registers contain the following global control and status registers for the SHA/MD5 Module:

- System control register that controls the mode of operation (**SHA_SYSCONFIG** register)
- μ DMA interrupt control registers (**SHA_DMAIM**, **SHA_DMARIS**, **SHA_DMAMIS**, and **SHA_DMAIC** registers, which reside in the Encryption Control Base address space)
- Interrupt status register (**SHA_IRQSTATUS** register)
- Enable register (**SHA_IRQENABLE** register)

15.1.1.2 Hash/HMAC Engine

The Hash/HMAC engine performs the SHA-1, SHA-2, or MD5 hash computation. When loaded with a data block, and optionally an intermediate digest, it independently performs the hash computation (64 or 80 rounds, depending on the algorithm) on that data block.

It can also start from the specified initial digest values instead of a loaded intermediate. Furthermore, it can perform the IPAD and OPAD XORs for MAC operations. The hash core does not perform any hash padding; this is performed in the Host Interface Block, where the data input registers are located. A loaded data block must always be a full 64 bytes (512 bits) long.

15.1.1.3 Hash Core Control

When the hash core is idle or done, a new hash operation can be started. Any additional information needed by the hash core (mode of operation, data to process, input digest if not starting from algorithm constants or continuing) must be provided by programming the SHA registers before the core can accept the operation.

15.1.1.4 Host Interface Bank

The Host Interface Bank can access the hash core for hashing individual 64-byte hash blocks. The Host Interface Bank contains registers such as the data FIFO (**SHA Data n Input (SHA_DATA_n_IN)** registers), the **SHA Inner Digest x (SHA_IDIGEST_X)** registers, and several control and status registers.

The Host Interface Block contains all relevant control logic for performing hash and HMAC computations on large (that is, larger than one hash block) blocks of data, including hash padding, final hash, and outer hash. It provides the necessary flow control to the SHA μ DMA and interrupt interface.

15.1.2 Power Management

To save power, the application can disable the clock to the SHA/MD5 module when not in use. The SHA/MD5 is clock gated by setting the **SHACFG** bit in the **Cryptographic Modules Clock Gating Request (CCMCGREQ)** register, CCM offset 0x204. The SHA in addition to the AES, DES, and Enhanced CRC can also be clock gated as a group by setting the **D0** bit in the **CRC and Cryptographic Modules Deep-Sleep Mode Clock Gating Control (DCGCCM)** register, System Control Module offset 0x874.

15.1.3 Reset Management

To perform a software reset of the SHA module, write a 1 to the **SOFTRESET** bit in the **SHA System Configuration (SHA_SYSCONFIG)** register. The **RESETDONE** bit in the **SHA System Status (SHA_SYSSTATUS)** register indicates that the software reset is complete when its value is 1. When the software reset completes, the **SOFTRESET** bit in the **SHA_SYSCONFIG** register is automatically reset. Software must ensure that the software reset completes before doing any operations.

The behavior of the software reset is the same as the hardware reset, except that the software reset bit resets this module without affecting the reset core domain of the entire device.

15.1.4 μ DMA and Interrupt Requests

The SHA/MD5 module can operate in μ DMA mode where the module can assert a μ DMA request for context in, context out, or data input. The μ DMA signals that can be generated are:

- Context In μ DMA request (SHA/MD5 0 Cin): Request for Key, Digest, Mode and LENGTH information
- Context Out μ DMA request (SHA/MD5 0 Cout): Request for read from HMAC
- Data In μ DMA request (SHA/MD5 0 Din): Request input data in multiples of 16 bytes

The SHA/MD5 Module be programmed to assert an interrupt when the μ DMA has completed its last transfer by programming the **SHA DMA Interrupt Mask (SHA_DMAIM)**, at the CRC and Cryptographic Modules (CCM) offset 0x010. The **SHA DMA Raw Interrupt Status (SHA_DMARIS)** register, at CCM offset 0x014, indicates when the μ DMA has completed and can be cleared by the **SHA DMA Interrupt Clear (SHA_DMAIC)** register at CCM offset 0x01C.

Note: The SHA module can only be accessed through privileged mode. If the μ DMA is used for SHA transfers, then the μ DMA's **DMA Channel Control (DMACHCTL)** register also needs to be programmed to allow for privileged accesses.

If context and data transfers are to be handled through software in Interrupt Mode, then the **SHA Interrupt Enable (SHA_IRQENABLE)**, offset 0x11C, can be used to enable interrupt triggering

when context out, context in, data in or data out is ready. The **SHA Interrupt Status (SHA_IRQSTATUS)**, offset 0x118, indicates when an interrupt is triggered.

Note: If the application uses Interrupt Mode, an interrupt is generated for each block of processed data. To support larger data flow, SHA μ DMA Mode should be used and the bits in the **SHA_IRQENABLE** register should be cleared.

Table 15-1. Interrupts and Events

| Event | Description |
|-------------------------------|--------------------------|
| SHA_IRQSTATUS[3]: CONTEXT_OUT | Context output interrupt |
| SHA_IRQSTATUS[1]: DATA_IN | Data input interrupt |
| SHA_IRQSTATUS[0]: CONTEXT_IN | Context input interrupt |

15.1.5 Operation Description

The SHA/MD5 Module can run the SHA-1, SHA-224, SHA-256, and MD5 algorithms, depending on the value of the **ALGO** bit field in the **SHA Mode (SHA_MODE)** register, offset 0x044, as listed in Table 15-2 on page 1072.

Table 15-2. SHA/MD5 Module Algorithm Selection

| ALGO Field Value in SHA_MODE Register | Description |
|---------------------------------------|----------------------------|
| 0x0 | MD5 algorithm selected |
| 0x1 | SHA-1 algorithm selected |
| 0x2 | SHA-224 algorithm selected |
| 0x3 | SHA-256 algorithm selected |

15.1.5.1 SHA Mode

Starting a New Hash

To start a new hash, follow these steps:

1. Set the **ALGO** bitfield in the **SHA_MODE** register, at offset 0x044, to 0x1, 0x2, or 0x3 to select SHA-1, SHA-224, or SHA-256, respectively.
2. Set the **ALGO_CONSTANT** bit in the **SHA_MODE** register to 1 to initialize all **SHA Inner/Outer Digest n** registers from **SHA_ODIGEST_A/SHA_IDIGEST_A** to **SHA_ODIGEST_H/SHA_IDIGEST_H** with their default values specified by the algorithm, and set the **SHA_DIGESTCOUNT** register to 0.
3. Set the **CLOSE_HASH** bit of the **SHA Mode (SHA_MODE)** register to let the SHA engine do the padding. If the Hash is computed in one shot, the length of the message can be any value up to 128 MB. To process an intermediate Hash digest, the **CLOSE_HASH** bit is set to 0, in which case the packets hashed must be 64 bytes; the last packet must be hashed with the **CLOSE_HASH** bit set to 1.
4. Specify the **LENGTH** field in the **SHA Length (SHA_LENGTH)** register of the hash data to process in bytes.

After the configuration is complete, the **INPUT_READY** status bit equals 1 in the **SHA Interrupt Status (SHA_IRQSTATUS)** register (regardless of whether or not the **M_INPUT_READY** bit in the **SHA_IRQENABLE** register is set. When this bit is set, it indicates the SHA engine can receive the

data to process. Data must be written to the 16 x 32-bit **SHA_DATA_n_IN** registers that provide storage for one 64-byte block of data. Unless the **CLOSE_HASH** bit is set, all of the **SHA_DATA_n_IN** input buffers must be filled. Data can be written by single write accesses to the 16 registers from a processor or by a DMA transfer.

For μ DMA transfers, the **DMA_EN** bit must be set in the **SHA_SYSCONFIG** register and the appropriate mask bits must be set in the **SHA_DMAIM** register before starting the new hash. Note that if the μ DMA is used for transfers, the **SHA_IRQENABLE** register should be clear so all interrupts are generated through the μ DMA interrupt registers.

The μ DMA must be configured to transfer 16 data words of 32 bits each time it is triggered by a μ DMA request from the SHA/MD5 Module. The 16 data words written are sent to the 16 **SHA_DATA_n_IN** registers.

The module detects that a 64-byte block is available, and then moves the data to a working register space for processing and asserts the **INPUT_READY** bit in the **SHA_IRQSTATUS** register to 1. If the **DMA_EN** bit in the **SHA_SYSCONFIG** register has been set to 1, a new μ DMA request triggers a new block transfer; otherwise, the processor polls the **INPUT_READY** bit and writes the 16 data words of 32 bits when it equals 1.

This operation is repeated until the length of the message to hash is reached. The **OUTPUT_READY** bit in the **SHA_IRQSTATUS** register then indicates that the hash operation is complete. If the **IT_EN** bit in the **SHA_SYSCONFIG** register is set, an interrupt (active low) is also generated to indicate the hash completion.

The processor can then read the eight digest registers A through H that contain the hash and/or HMAC result. If the hash is an intermediate result of a larger hash, the digest count register must also be read and saved.

Note: The number of digest registers used depends on the algorithm selected for the SHA/MD5 Module (MD5, SHA-1, SHA-224, or SHA-256), as shown in Table 15-3 on page 1073 and Table 15-4 on page 1074

Table 15-3. Outer Digest Registers

| Register | Address | MD5 (Read/Write) | SHA-1 (Read/Write) | SHA-2 (Read/Write) | HMAC Key Processing (write) |
|---------------|---------|--------------------------|---------------------------|------------------------|--------------------------------|
| SHA_ODIGEST_A | 0x000 | Outer digest [127:96] | Outer digest [159:128] | Outer digest [255:224] | HMAC Key [31:0] |
| SHA_ODIGEST_B | 0x004 | Outer digest [95:64] | Outer digest [127:96] | Outer digest [223:192] | HMAC key [63:32] |
| SHA_ODIGEST_C | 0x008 | Outer digest [63:32] | Outer digest [95:64] | Outer digest [191:160] | HMAC key [95:64] |
| SHA_ODIGEST_D | 0x00C | Outer digest [31:0] | Outer digest [63:32] | Outer digest [159:128] | HMAC key [127:96] |

| SHA_ODIGEST_F | 0x014 | | | Outer digest [95:64] | HMAC key [191:160] |
| SHA_ODIGEST_G | 0x018 | | | Outer digest [63:32] | HMAC key [223:192] |
| SHA_ODIGEST_H | 0x01C | | | Outer digest [31:0] | HMAC key [255:224] |

Table 15-4. Inner Digest Registers

| Register | Address | MD5 (Read/Write) | SHA-1 (Read/Write) | SHA-2 (Read/Write) | SHA-256 (Read/Write) | HMAC Key Processing (write) |
|---------------|---------|--------------------------|---------------------------|---------------------------|---------------------------|--------------------------------|
| SHA_IDIGEST_A | 0x020 | Inner digest [127:96] | Inner digest [159:128] | Inner digest [223:192] | Inner digest [255:224] | HMAC key [287:256] |
| SHA_IDIGEST_B | 0x024 | Inner digest [95:64] | Inner digest [127:96] | Inner digest [191:160] | Inner digest [223:192] | HMAC key [319:288] |
| SHA_IDIGEST_C | 0x028 | Inner digest [63:32] | Inner digest [95:64] | Inner digest [159:128] | Inner digest [191:160] | HMAC key [351:320] |
| SHA_IDIGEST_D | 0x02C | Inner digest [31:0] | Inner digest [63:32] | Inner digest [127:96] | Inner digest [159:128] | HMAC key [383:352] |
| SHA_IDIGEST_E | 0x030 | | Inner digest[31:0] | Inner digest [95:64] | Inner digest [127:96] | HMAC key [415:384] |
| SHA_IDIGEST_F | 0x034 | | | Inner digest [63:32] | Inner digest [95:64] | HMAC key [447:416] |
| SHA_IDIGEST_G | 0x038 | | | Inner digest [31:0] | Inner digest [63:32] | HMAC key [479:448] |
| SHA_IDIGEST_H | 0x03C | | | | Inner digest[31:0] | HMAC key [511:480] |

Note: Inner digests are initial, intermediate, and result digests.

Outer Digest Registers

The **SHA_ODIGEST_A** to **SHA_ODIGEST_H** registers are relevant only for HMAC operations; the contents are ignored for hash operations.

Before writing to the digest registers, the operation must be configured in the **SHA Mode (SHA_MODE)** register. For HMAC operations without key processing, the **HMAC_KEY_PROC** bit must be clear in the **SHA_MODE** register before starting operations. Once the algorithm has been programmed in the **SHA_MODE** register, only the relevant digest registers for the selected algorithm must be written:

- **SHA_ODIGEST_A** to **SHA_ODIGEST_D** registers for MD5
- **SHA_ODIGEST_A** to **SHA_ODIGEST_E** registers for SHA-1
- **SHA_ODIGEST_A** to **SHA_ODIGEST_H** registers for SHA-2 (224 to 256)

When HMAC key processing is enabled (**HMAC_KEY_PROC**=1), these registers must be written with the lower 256 bits of the HMAC key to be processed in little-endian format (first byte of key string in bits [7:0]).

Note: If the HMAC key is less than 512 bits, it must be properly padded with zeros: all 16 HMAC key registers must be written explicitly; the core does not pad. Additionally, if the HMAC key is larger than 512 bits, the host must perform a preprocessing step to reduce it to one 512-bit block. This involves hashing the large key and padding the hash result with zeros until it is 512 bits wide.

The computed outer digest can be read from these registers when the **SHA Interrupt Status (SHA_IRQSTATUS)** register when the **OUTPUT_READY** bit has been set indicating that the operation is done.

Note: If no HMAC key processing is performed, the value read is identical to the value written initially. The MD5 outer digest is available from registers **SHA_ODIGEST_A** to

SHA_ODIGEST_D, the SHA-1 outer digest from registers **SHA_ODIGEST_A** to **SHA_ODIGEST_E**, and the SHA-224 and SHA-256 outer digest from registers **SHA_ODIGEST_A** to **SHA_ODIGEST_H**.

Note: The HMAC key is not preserved. If another block must be authenticated using the same key, the key must be reloaded by the host. If the same key must be used many times, it is advisable to do a HMAC key processing-only pass to obtain the inner and outer digest precomputes and load these precomputes for subsequent passes (only the inner digest must be reloaded if the outer digest is not modified by the host), because this saves two hash blocks worth of computation time.

Inner Digest Registers

The **SHA_IDIGEST_A** to **SHA_IDIGEST_H** registers are used for HMAC and hash operations.

The inner/initial digest for HMAC and hash continue operations (**HMAC_KEY_PROC** = 0 and **ALGO_CONSTANT** = 0) must be written to these registers before starting the operation by writing to the **SHA_MODE** register. Only the relevant digest registers for the selected algorithm must be written:

- **SHA_IDIGEST_A** to **SHA_IDIGEST_D** registers for MD5
- **SHA_IDIGEST_A** to **SHA_IDIGEST_E** registers for SHA-1
- **SHA_IDIGEST_A** to **SHA_IDIGEST_H** registers for SHA-2

When **ALGO_CONSTANT** = 1 in the **SHA_MODE** register, the **SHA Inner Digest n (SHA_IDIGEST_n)** registers do not need to be written by the application because they are overwritten with the appropriate algorithm constants.

When **HMAC_KEY_PROC** is 1, these registers must be written with the upper 256 bits of the HMAC key to be processed in little-endian format (first byte of key string in bits [7:0]).

Note: If the HMAC key is less than 512 bits, it must be properly padded with zeros: all 16 HMAC key registers must be written explicitly; the core does not pad. Additionally, if the HMAC key is larger than 512 bits, the host must perform a preprocessing step to reduce it to one 512-bit block. This involves hashing the large key and padding the hash result with zeros until it is 512 bits wide.

The order of the bytes within the digest is such that it can be fed back unmodified into the little-endian data input when preprocessing HMAC keys larger than 64 bytes, or it can typically be inserted unmodified into a little-endian data stream (for example, IPSEC packets), regardless of the selected algorithm.

Note: The HMAC key or inner digest is not preserved. If another block must be authenticated using the same key, the key or inner digest must be reloaded by the host. If the same key must be used many times, it is advisable to do a HMAC key processing-only pass to obtain the inner and outer digest precomputes and load these precomputes for subsequent passes (only the inner digest must be reloaded if the outer digest is not modified by the host), because this saves two hash blocks worth of computation time.

Closing a Hash

The amount of data to hash is not necessarily a multiple of 64 bytes. The **CLOSE_HASH** bit in the **SHA_MODE** register is set to append padding so that the message size becomes a multiple of 64 bytes. Consequently, a minimum of 9 bytes must be added to the message. Nine bytes is the minimum number of bytes that contains the minimum 65-bit padding specified by FIPS 180-1.

If the size of the last block of data is less than or equal to 55 bytes, no additional 64-byte block is required. However, if the last block of data contains more than 55 bytes, an extra 64-byte block must be added to make the padding as specified by FIPS 180-1. This extra block is added automatically by the hardware; thus, the module is fed with a 64-byte block of data. However, appending a pad on the last block of data can result in the creation of an extra 64-byte block.

The one or two last blocks that contain the padding are processed in the same way as the other blocks. Hash completion is then indicated in the same way as for a new hash, and the hash result can be read in the digest registers. The **SHA_DIGESTCOUNT** register returns restored Digest Count + Length when it is read, and hashing completes.

Assuming a message of 129 bytes, Table 15-5 on page 1076 shows the SHA digest for three passes. Table 15-6 on page 1076 shows the SHA digest for one pass.

Table 15-5. SHA Digest Processed in Three Passes

| | Digest (A to E) | SHA_DIGESTCOUNT | SHA_MODE and SHA_LENGTH | SHA_DATA_n_IN |
|-------------|----------------------------|-----------------|--|----------------------------|
| First pass | | | WRITE: LENGTH=64 ALGO (dependent on the algorithm to apply) ALGO_CONSTANT=1 CLOSE_HASH=0 | First 64 bytes of message |
| Second pass | Round 1 digest calculation | WRITE: 64 | WRITE: LENGTH=64 ALGO (dependent on the algorithm to apply) ALGO_CONSTANT=0 CLOSE_HASH=0 | Second 64 bytes of message |
| Third pass | Round 2 digest calculation | WRITE: 128 | Write: LENGTH=1 ALGO (dependent on the algorithm to apply) ALGO_CONSTANT=0 CLOSE_HASH=1 | Last byte of message |
| | Final digest | READ: 129 | | |

If the three passes are not performed in succession, the digest registers must be saved and restored for the next use of the SHA/MD5 engine. If the rounds are performed consecutively, there is no need to do anything with the digest registers.

Table 15-6. SHA Digest Processed in One Pass

| | Digest (A to E) | SHA_DIGEST_COUNT | SHA_MODE and SHA_LENGTH | SHA_DATA_n_IN |
|------------|-----------------|------------------|---|---------------------------|
| First pass | | | WRITE: LENGTH=129 ALGO (dependent on the algorithm to apply) ALGO_CONSTANT=1 CLOSE_HASH=1 | First 64 bytes of message |

Table 15-6. SHA Digest Processed in One Pass (continued)

| | Digest (A to E) | SHA_DIGEST_COUNT | SHA_MODE and SHA_LENGTH | SHA_DATA_n_IN |
|--|----------------------------|------------------|-------------------------|----------------------------|
| | Round 1 digest calculation | | | Second 64 bytes of message |
| | Round 2 digest calculation | | | Last byte of message |
| | Final digest | Read: 129 | | |

15.1.5.2 MD5 Mode

Starting a New Hash

To start a new hash, perform the following steps:

1. Set the **ALGO** bit field in the **SHA_MODE** register to 0x0 to select the MD5 algorithm.
2. Set the **ALGO_CONSTANT** bit to 1 in the **SHA_MODE** register to initialize all digest registers from **SHA_ODIGEST_A/SHA_IDIGEST_A** to **SHA_ODIGEST_H/SHA_IDIGEST_H** with default values specified by the algorithm, and set the **SHA_DIGESTCOUNT** register to 0.
3. Specify the **LENGTH** field in the **SHA_LENGTH** register of the hash data to process in bytes.
4. Set the **CLOSE_HASH** bit in the **SHA_MODE** register to let the SHA/MD5 engine do the padding. If MD5 is computed in one shot, the length of the message can be any value up to . To process an intermediate MD5 digest, the **CLOSE_HASH** bit is set to 0, in which case packets to be hashed must be 64 bytes; the last packet must be hashed with the **CLOSE_HASH** bit set to 1.

After the configuration is complete, the hash engine can receive the data to process (the **INPUT_READY** bit is 1 in the **SHA_IRQSTATUS** register). Data must be written to the 16 x 32-bit **SHA_DATA_n_IN** registers that provide storage for one 64-byte block of data. Unless the **CLOSE_HASH** bit is set in the **SHA_MODE** register, the **SHA_DATA_n_IN** 64-byte input buffer must be filled. Data can be written by single write transactions to the 16 registers from a processor or by a μ DMA transfer.

For a μ DMA transfer, the **SDAM_EN** bit must be set in the **SHA_SYSCONFIG** register before starting the new hash and the μ DMA channel for SHA/MD5 0 Data In Request must be configured. The μ DMA must be configured to the appropriate hash transfer size. See “Micro Direct Memory Access (μ DMA)” on page 708 for more information on programming the μ DMA. A μ DMA done is asserted after the last **SHA_DATA_n_IN** register is filled..

The module detects that a 64-byte block is available, and then moves the data to a working register space for processing and sets the **INPUT_READY** bit to 1 in the **SHA_IRQSTATUS** register. If the **DMA_EN** bit is set in the **SHA_SYSCONFIG** register, then a new μ DMA request triggers a new block transfer; otherwise, the processor polls the **INPUT_READY** bit in the **SHA_IRQSTATUS** register and writes the 16 data words of 32 bits when it equals 1.

This operation repeats until the length of the message to hash is reached. The **OUTPUT_READY** bit in the **SHA_IRQSTATUS** register then indicates that the hash operation is complete. If the **IT_EN** bit in the **SHA_SYSCONFIG** register is set, an interrupt (active low) is also generated to indicate the hash completion.

Closing a Hash

The amount of data to hash is not necessarily a multiple of 64 bytes. In this case, the CLOSE_HASH bit in the SHA_MODE register must be set to append padding so that the message size becomes a multiple of 64 bytes. See the previous MD5 algorithm for more information on padding.

The module is fed with a 64-byte block of data, as long as enough data is available. However, a pad is appended on the last block of data. This can result in the creation of an extra 64-byte block.

The one or two last blocks that contain the padding are processed the same way as the other blocks. Hash completion is then indicated the same way as for a new hash, and the 128-bit result can be read in the digest registers. The **SHA_DIGESTCOUNT** register returns restored digest count and length when it is read, and hashing completes.

15.1.5.3 Generating an Software Interrupt

If the IT_EN bit is 1 in the **SHA_SYSCONFIG** register, an interrupt is generated at the completion of the hash by the following steps:

1. Receive last block of data (= 64 bytes). (The number of data bytes defined by the **SHA_LENGTH** register is received in the digest registers, from **SHA_ODIGEST_A/SHA_IDIGEST_A** to **SHA_ODIGEST_H/SHA_IDIGEST_H**.)
2. If required, apply padding to the last block of data.
3. Hash the last block of data (80 cycles in SHA-1 mode and 64 cycles in MD5, SHA-224, and SHA-256 modes).
4. If required, add an extra 64-byte block of data to complete the padding.
5. Hash this extra block of data (80 cycles in SHA-1 mode and 64 cycles in MD5, SHA-224, and SHA-256 modes).
6. An interrupt is generated (active low).

15.1.6 SHA/MD5 Performance Information

The following table lists the performance for all supported key sizes and modes of operations. It assumed that the engine is kept fully utilized (that is, the host is supplying input block and retrieving output blocks in such a way, that the engine never has to wait for input) and that the previous output has been retrieved before the next output is ready.

Maximum throughput does not include per operation overhead cycles, as the impact on the throughput depends on the size of the block being processed, and would be negligible for large blocks anyway.

Table 15-7. SHA/MD5 Performance

| Operation | Algorithm | Cycles per operation | Cycles per block |
|-----------|-----------|----------------------|------------------|
| Hash | MD5 | 0 / 65 | 65 |
| | SHA-1 | 0 / 81 | 81 |
| | SHA-224 | 0 / 65 | 65 |
| | SHA-256 | 0 / 65 | 65 |

Table 15-7. SHA/MD5 Performance (continued)

| Operation | Algorithm | Cycles per operation | Cycles per block |
|-----------------------|-----------|----------------------|------------------|
| HMAC from Key | MD5 | 196 / 261 | 65 |
| | SHA-1 | 244 / 325 | 81 |
| | SHA-224 | 196 / 261 | 65 |
| | SHA-256 | 196 / 261 | 65 |
| | MD5 | 66 / 131 | 65 |
| HMAC from precomputes | SHA-1 | 82 / 163 | 81 |
| | SHA-224 | 66 / 131 | 65 |
| | SHA-256 | 66 / 131 | 65 |

Note: An extra block needs to be processed if the length of the data block to be hashed module 64 is 0 or equal to 56.

15.1.7 SHA/MD5 Programming Guide

This section covers the hardware programming sequences for configuration and use of the SHA/MD5 Module.

15.1.7.1 Global Initialization

Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the SHAM is used for the first time after a device reset.

1. When reset has completed, enable the SHA/MD5 Module by setting the `R0` bit in the **CRC And Cryptographic Modules Run Mode Clock Gating Control (RCGCCM)** register, System Control offset 0x674. When the `R0` bit is set in the **CRC and Cryptographic Modules (PRCCM)** register, System Control offset 0xA74 register, the SHA/MD5 Module is powered and ready to be configured.
2. Configure the SHA μ DMA channels for Context In, Context Out, Data In, and/or Data Out by programming the appropriate encoding value in the **DMA Channel Map Select n (DMACHMAPn)** register in the μ DMA module, offset 0x510. For more information on how to program channel assignments as well as enabling burst and the configured channels, refer to “Micro Direct Memory Access (μ DMA)” on page 708.
3. Execute a software reset by setting the `SOFTRESET` bit in the **SHA_SYSCONFIG** register. When reset is complete, the `RESETDONE` bit reads as 1 in the **SHA_SYSSTATUS** register.
4. If the SHA channels are configured in the μ DMA, enable the required SHA DMA requests by programming bits [9:5] of the **SHA_SYSCONFIG** register, in addition to the completion interrupts in the **SHA DMA Interrupt Mask (SHA_DMAIM)** register, CRC and Cryptographic Modules offset 0x020.

Starting a New HMAC using the SHA-1 Hash Function and HMAC Key Processing

The following procedure is used to begin a new HMAC operation, starting from initial digest values.

1. Load the key value in the **SHA_ODIGEST_A/SHA_IDIGEST_A** to **SHA_ODIGEST_H/SHA_IDIGEST_H** registers.

2. Pad the rest of the SHA_ODIGEST_x and SHA_IDIGEST registers with zeros.
3. Load the message in the **SHA_DATA_n_IN** FIFO registers.
4. Enable HMAC key processing by setting the HMAC_KEY_PROC bit in the **SHA_MODE** register.
5. Select the SHA-1 hash function by programming the ALGO bit in the **SHA_MODE** register to 0x1.
6. Select the already loaded key by programming the ALGO_CONSTANT bit in the SHA_MODE register to 0x0.
7. Set the CLOSE_HASH bit and the HMAC_OUTER_HASH bit in the **SHA_MODE** register so that appropriate padding is inserted and the outer hash is performed immediately after the inner hash has finished.
8. Program the **SHA_LENGTH** register with the block length. Writing this register triggers the HMAC engine to begin processing.

Note: If more than one pass is used during the process (SHA_MODE[4] CLOSE_HASH == 0x0), the block length value must be a 64-byte multiple. From this point, three operational modes are possible to continue with the processing: polling, interrupt, and DMA. For more information, see the Operational Modes Configuration section.

Subsequence - Continuing a Prior HMAC Using the SHA-1 Hash Function

The procedure in continues a prior HMAC calculation interrupted from a high priority task.

Table 15-8. Continuing a Prior HMAC

| Step | Register/Bit Field/Programming Model | Value |
|--|--------------------------------------|-------|
| Load the initial digest for the used hash algorithm. | SHA_IDIGEST_i[31:0] DATA | - |
| Restore the digest counter with the value before the switch to the high-priority task. | SHA_DIGEST_COUNT[31:0] COUNT | - |
| Use the already loaded in the engine key. | SHA_MODE[5] HMAC_KEY_PROC | 0x0 |
| Do not use the constants of the selected hash algorithm. | SHA_MODE[3] ALGO_CONSTANT | 0x0 |
| Select the SHA-1 hash algorithm. | SHA_MODE[2:1] ALGO | 0x1 |
| IF: This is the last 64-byte data block from the input message? | User decision | |
| Close the hash; an appropriate padding is added. | SHA_MODE[4] CLOSE_HASH | 0x1 |
| ENDIF | | |
| Load the block length; this is the trigger to start processing. | SHA_LENGTH[31:0] LENGTH | - |

Note: This initial digest is the intermediate digest from the previous calculation before switching to the high priority task. The value is equal to context1 in .

Note: The value is equal to context2 in .

Note: The block length is equal to the context3 value in .

Subsequence - Hashing a Key Bigger than 512 Bits with the SHA-1 Hash Function

The procedure in creates a hash value from the key in only one pass.

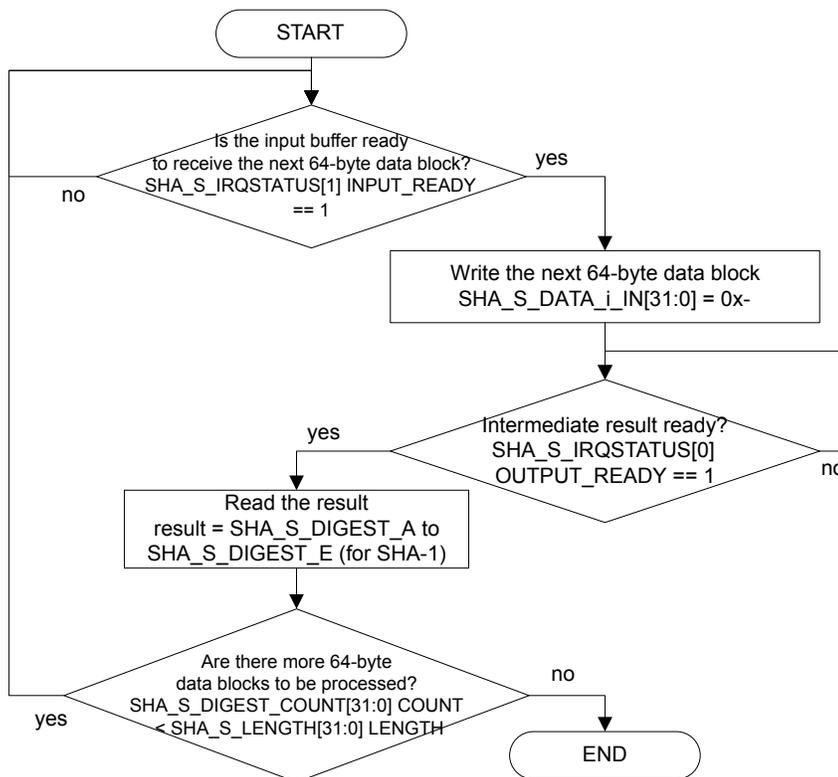

Table 15-9. SHA-1 Apply on the Key

| Step | Register/Bit Field/Programming Model | Value |
|--|--------------------------------------|-------|
| Load the first part of the key. (Here, the key is like a message.) | SHA_DATA_n_IN (i = 0 to 15) | - |
| Select the SHA-1 hash function. | SHA_MODE[2:1] ALGO | 0x1 |
| Select a new hash operation. | SHA_MODE[3] ALGO_CONSTANT | 0x1 |
| Close the hash; the key is processed in single pass. | SHA_MODE[4] CLOSE_HASH | 0x1 |

Operational Modes Configuration

SHA/MD5 Polling Mode

Figure 15-2 on page 1081 shows the SHA/MD5 polling mode. SHA/MD5 polling mode uses the following registers: SHA_IRQSTATUS, SHA_DATA_n_IN, SHA_ODIGEST_A, SHA_DIGEST_COUNT, and SHA_LENGTH.

Figure 15-2. SHA/MD5 Polling Mode

SHA/MD5 Interrupt Mode

The procedure in configures the SHA/MD5 module to work in interrupt-based mode. (For the interrupt subroutine, see the Interrupt Servicing section.)

Table 15-10. Interrupt Mode

| Step | Register/Bit Field/Programming Model | Value |
|---|--------------------------------------|-------|
| Enable the interrupt request to the Cortex-A8 MPU INTC. | SHA_SYSCONFIG[2] IT_EN | 0x1 |

Table 15-10. Interrupt Mode (continued)

| Step | Register/Bit Field/Programming Model | Value |
|---|--------------------------------------|-------|
| Load the message length; this is the trigger to start processing. | SHA_LENGTH[31:0] LENGTH | - |

SHA/MD5 DMA Mode

The procedure in configures the SHA/MD5 module to work in DMA-based mode.

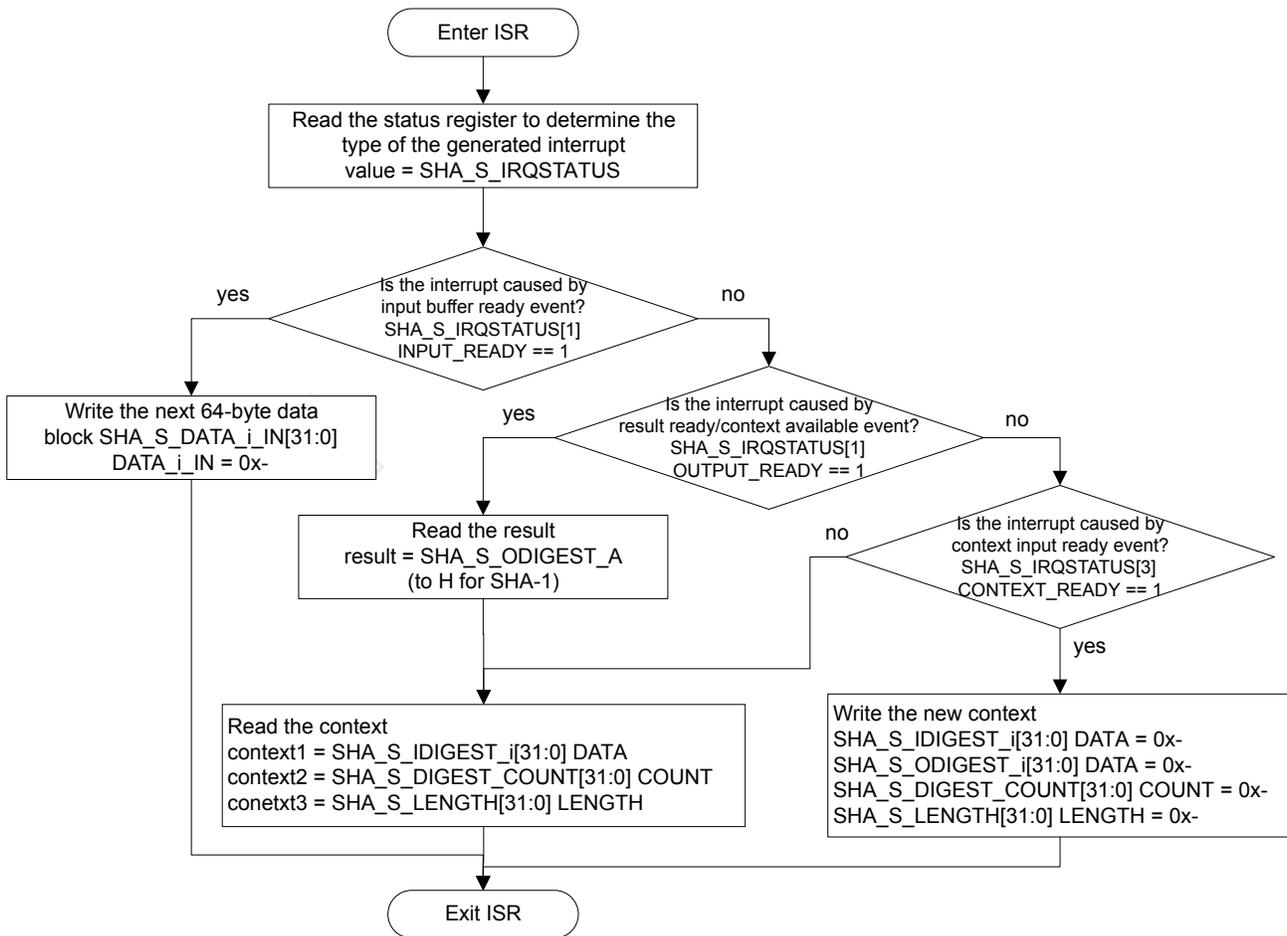

Table 15-11. DMA Mode

| Step | Register/Bit Field/Programming Model | Value |
|---|--------------------------------------|-------|
| Enable the DMA request to the CDMA controller. | SHA_SYSCONFIG[3] DMA_EN | 0x1 |
| Load the message length; this is the trigger to start processing. | SHA_LENGTH[31:0] LENGTH | - |

SHA/MD5 Event Servicing**Interrupt Servicing**

This section describes the interrupt event servicing of the module. Figure 15-3 on page 1083 shows the interrupt subroutine. The following registers are used in the SHA/MD5 interrupt routine: SHA_IRQSTATUS, SHA_DATA_n_IN, SHA_ODIGEST_A, SHA_DIGEST_COUNT, SHA_LENGTH, and SHA_IDIGEST_A.

Figure 15-3. SHA/MD5 Interrupt Subroutine

15.2 SHA/MD5 Register Map

Table 15-12 on page 1083 lists the SHA/MD5 registers. The SHA Module comprises registers that exist at an offset relative to the SHA/MD5 Module base address and a small set of SHA/MD5 μ DMA interrupt registers that exist at an offset relative to an CRC and Cryptographic Modules base address. The SHA/MD5 Module register offsets are relative to the base address 0x4403.4000. The SHA μ DMA offsets are relative to the base address 0x4403.0000 .

Table 15-12. SHA/MD5 Register Map

| Offset | Name | Type | Reset | Description | See page |
|---|---------------|------|-------------|--------------------|----------|
| SHA/MD5 Module Registers (SHA/MD5 Module Offset) | | | | | |
| 0x000 | SHA_ODIGEST_A | RW | 0x0000.0000 | SHA Outer Digest A | 1087 |

15.3 SHA/MD5 Register Descriptions

This section describes the SHA/MD5 registers.

Note: The SHA/MD5 registers are limited to 32-bit data accesses; 8- and 16-bit accesses are not allowed and can corrupt register contents.

The first 16 registers of HIB1 are the outer and inner digest registers.

Table 15-13. SHA/MD5 Inner/Outer Digest/HMAC Key Register Mapping

| Register Name | Address Offset | MD5 (read/write) | SHA-1 (read/write) | SHA-2 (read/write) | | HMAC key proc (write) |
|---------------|----------------|-----------------------|------------------------|------------------------|------------------------|-----------------------|
| SHA_ODIGEST_A | 0x00000000 | Outer digest [127:96] | Outer digest [159:128] | Outer digest [255:224] | | HMAC key [31,0] |
| SHA_ODIGEST_B | 0x00000004 | Outer digest [95:64] | Outer digest [127:96] | Outer digest [223:192] | | HMAC key [63,32] |

|-----------|------|------|-------------|-----------------|
| 31:0 | DATA | RW | 0x0000.0000 | Digest/Key Data |

Register 17: SHA Digest Count (SHA_DIGEST_COUNT), offset 0x040

This register is written with the initial digest count and can be read to determine the digest count result. Note that for Initial Digest Count writes, bits 5:0 must be zero. This register is written the initial digest byte count when both the `HMAC_KEY_PROC` bit and the `ALGO_CONSTANT` bit is zero in the `SHA_MODE` register. When either the `HMAC_KEY_PROC` bit or the `ALGO_CONSTANT` bit is 1, this register does not need to be written because it is overwritten with 64 or 0 automatically. When starting an HMAC operation from precomputes (`HMAC_KEY_PROC=0`), the value 64 must be written in the `SHA_DIGESTCOUNT` register. Note that the value written should always be a 64 byte multiple, the lower 6 bits written are ignored. The updated digest byte count (initial digest byte count + bytes processed) can be read from this register when the status register indicates that the operation is done or when a μ DMA context out is requested.

SHA Digest Count (SHA_DIGEST_COUNT)

|-----------|---------------------------------------|------|-------|--|---|--------------|---|---------------------------------------|
| 31:8 | reserved | RO | 0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. | | | | |
| 7 | HMAC_OUTER_HASH | RW | 0 | <p>HMAC Outer Hash Processing Enable</p> <p>This bit is written to indicate that the outer hash should be performed on the hash digest when the inner hash has finished. The inner hash finishes when the length of hash has been processed the final inner hash is performed (if <code>CLOSE_HASH</code> was set to 1).</p> <p>This bit should normally be set together with <code>CLOSE_HASH</code> to finish the inner hash first, or immediately when block length is zero (HMAC continue with the just outer hash to be done). This bit is auto-cleared when outer hash is finished.</p> <p>Value Description</p> <table border="0"> <tr> <td>0</td> <td>No operation</td> </tr> <tr> <td>1</td> <td>Enable HMAC processing of outer hash.</td> </tr> </table> <p>This bit self-clears when outer hash is finished.</p> | 0 | No operation | 1 | Enable HMAC processing of outer hash. |
| 0 | No operation | | | | | | | |
| 1 | Enable HMAC processing of outer hash. | | | | | | | |
| 6 | reserved | R | 0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. | | | | |

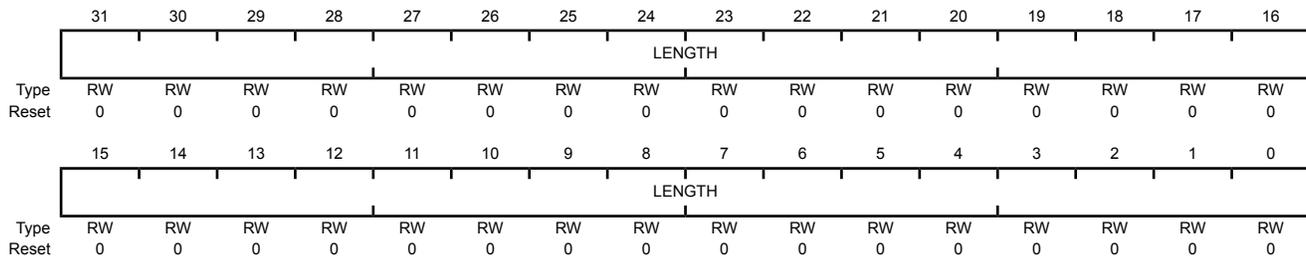

| Bit/Field | Name | Type | Reset | Description | | | | | | | | | | | | | | | | |
|-----------|---|------|-------|---|-----|---|-----|---|-----|-------|-----|----------|-----|---------|-----|----------|-----|---------|-----|----------|
| 5 | HMAC_KEY_PROC | RW | 0x00 | <p>HMAC Key Processing Enable</p> <p>This bit enables HMAC key processing on the 512-bit HMAC key loaded into the SHA_IDIGEST_A through SHA_IDIGEST_H registers and the SHA_ODIGEST_A through SHA_ODIGEST_H register block. Once HMAC key processing is finished, this bit is automatically cleared and the resulting Inner and Outer digest is available in the SHA_IDIGEST_x and SHA_ODIGEST_x respectively.</p> <p>After key processing is complete, regular hash processing begins until the block length is exhausted.</p> <p>Value Description</p> <table border="1"> <tr> <td>0</td> <td>No operation</td> </tr> <tr> <td>1</td> <td>Enable HMAC key processing. This bit is automatically cleared once HMAC key processing is finished.</td> </tr> </table> | 0 | No operation | 1 | Enable HMAC key processing. This bit is automatically cleared once HMAC key processing is finished. | | | | | | | | | | | | |
| 0 | No operation | | | | | | | | | | | | | | | | | | | |
| 1 | Enable HMAC key processing. This bit is automatically cleared once HMAC key processing is finished. | | | | | | | | | | | | | | | | | | | |
| 4 | CLOSE_HASH | RW | 0 | <p>Performs the padding, the Hash/HMAC will be 'closed' at the end of the block, as per MD5/SHA-1/SHA-2 specification (that is, appropriate padding is added), or no padding is done, allowing the hash to be continued later. However, if the Hash/HMAC is not closed, then the Block Length must be a multiple of 64 bytes to ensure correct operation. Auto cleared internally when hash closed.</p> <p>Value Description</p> <table border="1"> <tr> <td>0</td> <td>No padding, hash computation can be continued.</td> </tr> <tr> <td>1</td> <td>Last packet will be padded.</td> </tr> </table> | 0 | No padding, hash computation can be continued. | 1 | Last packet will be padded. | | | | | | | | | | | | |
| 0 | No padding, hash computation can be continued. | | | | | | | | | | | | | | | | | | | |
| 1 | Last packet will be padded. | | | | | | | | | | | | | | | | | | | |
| 3 | ALGO_CONSTANT | RW | 0 | <p>The initial digest register will be overwritten with the algorithm constants for the selected algorithm when hashing and the initial digest count register will be reset to 0. This will start a normal hash operation. When continuing an existing hash or when performing an HMAC operation, this register must be set to 0 and the intermediate/inner digest or HMAC key and digest count need to be written to the context input registers prior to writing SHA_MODE. Auto cleared internally after first block processed.</p> <p>Value Description</p> <table border="1"> <tr> <td>0</td> <td>Use precalculated digest (from another operation)</td> </tr> <tr> <td>1</td> <td>Use constants of the selected algorithm</td> </tr> </table> | 0 | Use precalculated digest (from another operation) | 1 | Use constants of the selected algorithm | | | | | | | | | | | | |

Register 19: SHA Length (SHA_LENGTH), offset 0x048

WRITE: Block Length/Remaining Byte Count (bytes) READ: Remaining Byte Count. The value programmed MUST be a 64-byte multiple if Close Hash is set to 0. This register is also the trigger to start processing: once this register is written, the core will commence requesting input data via DMA or IRQ (if programmed length > 0) and start processing. The remaining byte count for the active operation can be read from this register when the interrupt status register indicates that the operation is suspended due to a context switch request.

SHA Length (SHA_LENGTH)

Base 0x4403.4000
Offset 0x048
Type RW, reset 0x0000.0000

15.4 SHA/MD5 μ DMA Control Register Descriptions (Encryption Control Offset)

This section lists and describes the SHA/MD5 μ DMA registers, in numerical order by address offset. Registers in this section are relative to the Encryption Control base address of 0x4403.0000.

Note: The SHA module can only be accessed through privileged mode. If the μ DMA is used for SHA transfers, then the μ DMA's **DMA Channel Control (DMACHCTL)** register also needs to be programmed to allow for privileged accesses.

Note: If the application uses SHA μ DMA interrupt triggers, the bits in the **SHA_IRQENABLE** register should be cleared.

Register 41: SHA DMA Interrupt Mask (SHA_DMAIM), offset 0x010

The **SHA DMA Interrupt Mask (SHA_DMA_IM)** register controls interrupt behavior and are used to program which interrupts are suppressed.

SHA DMA Interrupt Mask (SHA_DMAIM)

Base
Offset 0x010
Type RW, reset 0x0000.0000

| | | | | | | | | | | | | | | | | |
|-------|----------|----|----|----|----|----|----|----|----|----|----|----|----|------|-----|-----|
| | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|------------|---|
| 31:3 | reserved | RO | 0x0000.000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 2 | COUT | RW | 0 | Context Out DMA Done Interrupt Mask If this bit is unmasked, an interrupt is generated when the μ DMA completes the output context read from the internal register. Value Description 0 The COUT interrupt is suppressed and not sent to the interrupt controller. 1 The COUT interrupt is sent to the interrupt controller. |
| 1 | DIN | RW | 0 | Data In DMA Done Interrupt Mask If this bit is unmasked, an interrupt is generated when the μ DMA writes the last word of input data to the internal FIFO of the engine. Value Description 0 The DIN interrupt is suppressed and not sent to the interrupt controller. 1 The DIN interrupt is sent to the interrupt controller. |
| 0 | CIN | RW | 0 | Context In DMA Done Interrupt Mask If this bit is unmasked, an interrupt is generated when the μ DMA completes a context write to the internal register. Value Description 0 The CIN interrupt is suppressed and not sent to the interrupt controller. 1 The CIN interrupt is sent to the interrupt controller. |

Register 42: SHA DMA Raw Interrupt Status (SHA_DMARIS), offset 0x014

The **SHA DMA Raw Interrupt Status (SHA_DMA_RIS)** register contains the raw interrupt status. If any of these bits read 1, the processor is interrupted if the corresponding masked interrupt status bit is set to '1.'

16 General-Purpose Timers

Programmable timers can be used to count or time external events that drive the Timer input pins. The TM4C129XKCZAD General-Purpose Timer Module (GPTM) contains 16/32-bit GPTM blocks. Each 16/32-bit GPTM block provides two 16-bit timers/counters (referred to as Timer A and Timer B) that can be configured to operate independently as timers or event counters, or concatenated to operate as one 32-bit timer or one 32-bit Real-Time Clock (RTC). Timers can also be used to trigger μ DMA transfers.

In addition, timers can be used to trigger analog-to-digital conversions (ADC). The ADC trigger signals from all of the general-purpose timers are ORed together before reaching the ADC module, so only one timer should be used to trigger ADC events.

The GPT Module is one timing resource available on the Tiva™ C Series microcontrollers. Other timer resources include the System Timer (SysTick) (see 146) and the PWM timer in the PWM module (see “PWM Timer” on page 1929).

The General-Purpose Timer Module (GPTM) contains eight 16/32-bit GPTM blocks with the following functional options:

- Operating modes:
 - 16- or 32-bit programmable one-shot timer
 - 16- or 32-bit programmable periodic timer
 - 16-bit general-purpose timer with an 8-bit prescaler
 - 32-bit Real-Time Clock (RTC) when using an external 32.768-KHz clock as the input
 - 16-bit input-edge count- or time-capture modes with an 8-bit prescaler
 - 16-bit PWM mode with an 8-bit prescaler and software-programmable output inversion of the PWM signal
 - The System Clock or a global Alternate Clock (ALTCLK) resource can be used as timer clock source. The global ALTCLK can be:
 - PIOSC
 - Hibernation Module Real-time clock output (RTCOSC)
 - Low-frequency internal oscillator (LFIOSC)
- Count up or down
- Sixteen 16/32-bit Capture Compare PWM pins (CCP)
- Daisy chaining of timer modules to allow a single timer to initiate multiple timing events
- Timer synchronization allows selected timers to start counting on the same clock cycle
- ADC event trigger
- User-enabled stalling when the microcontroller asserts CPU Halt flag during debug (excluding RTC mode)

- Ability to determine the elapsed time between the assertion of the timer interrupt and entry into the interrupt service routine
- Efficient transfers using Micro Direct Memory Access Controller (μDMA)
 - Dedicated channel for each timer
 - Burst request generated on timer interrupt

16.1 Block Diagram

In the block diagram, the specific Capture Compare PWM (CCP) pins available depend on the TM4C129XKCZAD device. See Table 16-1 on page 1105 for the available CCP pins and their timer assignments.

Figure 16-1. GPTM Module Block Diagram

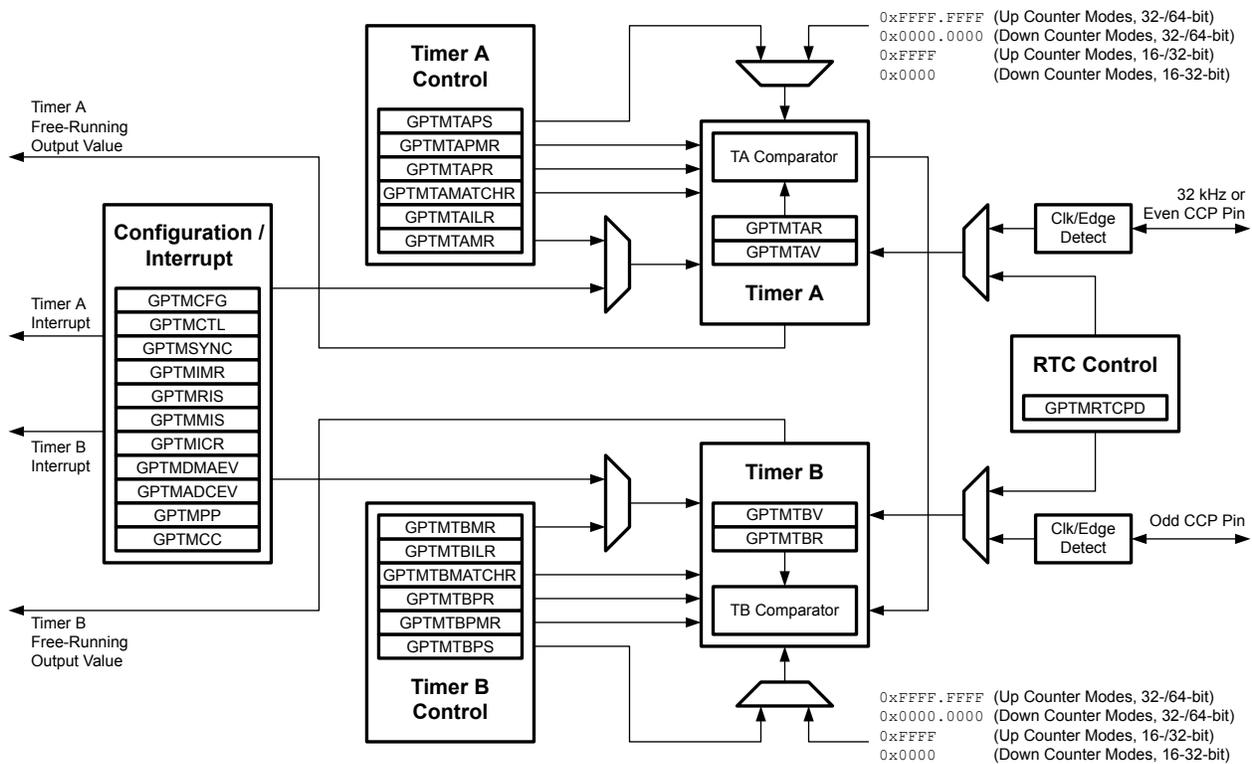

Table 16-1. Available CCP Pins

16.2 Signal Description

The following table lists the external signals of the GP Timer module and describes the function of each. The GP Timer signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for these GP Timer signals. The **AFSEL** bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 803) should be set to choose the GP Timer function. The number in parentheses is the encoding that must be programmed into the **PMC_n** field in the **GPIO Port Control (GPIOCTL)** register (page 820) to assign the GP Timer signal to the specified GPIO port pin. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 772.

Table 16-2. General-Purpose Timers Signals (212BGA)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description |

16.3 Functional Description

The main components of each GPTM block are two free-running up/down counters (referred to as Timer A and Timer B), two prescaler registers, two match registers, two prescaler match registers, two shadow registers, and two load/initialization registers and their associated control functions. The exact functionality of each GPTM is controlled by software and configured through the register interface. Timer A and Timer B can be used individually, in which case they have a 16-bit counting range for the 16/32-bit GPTM blocks. In addition, Timer A and Timer B can be concatenated to provide a 32-bit counting range for the 16/32-bit GPTM blocks. Note that the prescaler can only be used when the timers are used individually.

The available modes for each GPTM block are shown in Table 16-3 on page 1108. Note that when counting down in one-shot or periodic modes, the prescaler acts as a true prescaler and contains the least-significant bits of the count. When counting up in one-shot or periodic modes, the prescaler acts as a timer extension and holds the most-significant bits of the count. In input edge count, input

edge time and PWM mode, the prescaler always acts as a timer extension, regardless of the count direction.

Table 16-3. General-Purpose Timer Capabilities

| Mode | Timer Use | Count Direction | Counter Size | Prescaler Size ^a |
|------------|--------------|-----------------|--------------|-----------------------------|
| One-shot | Individual | Up or Down | 16-bit | 8-bit |
| | Concatenated | Up or Down | 32-bit | - |
| Periodic | Individual | Up or Down | 16-bit | 8-bit |
| | Concatenated | Up or Down | 32-bit | - |
| RTC | Concatenated | Up | 32-bit | - |
| Edge Count | Individual | Up or Down | 16-bit | 8-bit |
| Edge Time | Individual | Up or Down | 16-bit | 8-bit |
| PWM | Individual | Down | 16-bit | 8-bit |

a. The prescaler is only available when the timers are used individually

Software configures the GPTM using the **GPTM Configuration (GPTMCFG)** register (see page 1126), the **GPTM Timer A Mode (GPTMTAMR)** register (see page 1127), and the **GPTM Timer B Mode (GPTMTBMR)** register (see page 1132). When in one of the concatenated modes, Timer A and Timer B can only operate in one mode. However, when configured in an individual mode, Timer A and Timer B can be independently configured in any combination of the individual modes.

16.3.1 GPTM Reset Conditions

After reset has been applied to the GPTM module, the module is in an inactive state, and all control registers are cleared and in their default states. Counters Timer A and Timer B are initialized to all 1s, along with their corresponding registers:

- Load Registers:
 - **GPTM Timer A Interval Load (GPTMTAILR)** register (see page 1154)
 - **GPTM Timer B Interval Load (GPTMTBILR)** register (see page 1155)
- Shadow Registers:
 - **GPTM Timer A Value (GPTMTAV)** register (see page 1164)
 - **GPTM Timer B Value (GPTMTBV)** register (see page 1165)

The following prescale counters are initialized to all 0s:

- **GPTM Timer A Prescale (GPTMTAPR)** register (see page 1158)
- **GPTM Timer B Prescale (GPTMTBPR)** register (see page 1159)
- **GPTM Timer A Prescale Snapshot (GPTMTAPS)** register (see page 1167)
- **GPTM Timer B Prescale Snapshot (GPTMTBPS)** register (see page 1168)

16.3.2 Timer Clock Source

The general purpose timer has the capability of being clocked by either the system clock or an alternate clock source. By setting the `ALTCLK` bit in the **GPTM Clock Configuration (GPTMCC)**

register, offset 0xFC8, software can select an alternate clock source as programmed in the **Alternate Clock Configuration (ALTCLKCFG)** register, offset 0x138 in the System Control Module. The alternate clock source options available are PIOSC, RTCOSC and LFIOSC. Refer to “System Control” on page 231 for additional information.

Note: When the ALTCLK bit is set in the **GPTMCC** register to enable using the alternate clock source, the synchronization imposes restrictions on the starting count value (down-count), terminal value (up-count) and the match value. This restriction applies to all modes of operation. Each event must be spaced by 4 Timer (ALTCLK) clock periods + 2 system clock periods. If some events do not meet this requirement, then it is possible that the timer block may need to be reset for correct functionality to be restored.

Example: $ALTCLK = T_{PIOSC} = 62.5\text{ns}$ (16Mhz Trimmed)

$T_{hclk} = 1\mu\text{s}$ (1Mhz)

$4 * 62.5\text{ns} + 2 * 1\mu\text{s} = 2.25\mu\text{s}$ $2.25\mu\text{s} / 62.5\text{ns} = 36$ or 0x23

The minimum values for the periodic or one-shot with a match interrupt enabled are:

GPTMTAMATCHR = 0x23 **GPTMTAILR** = 0x46

16.3.3 Timer Modes

This section describes the operation of the various timer modes. When using Timer A and Timer B in concatenated mode, only the Timer A control and status bits must be used; there is no need to use Timer B control and status bits. The GPTM is placed into individual/split mode by writing a value of 0x4 to the **GPTM Configuration (GPTMCFG)** register (see page 1126). In the following sections, the variable "n" is used in bit field and register names to imply either a Timer A function or a Timer B function. Throughout this section, the timeout event in down-count mode is 0x0 and in up-count mode is the value in the **GPTM Timer n Interval Load (GPTMTnILR)** and the optional **GPTM Timer n Prescale (GPTMTnPR)** registers, with the exception of RTC mode.

16.3.3.1 One-Shot/Periodic Timer Mode

The selection of one-shot or periodic mode is determined by the value written to the T_nMR field of the **GPTM Timer n Mode (GPTMTnMR)** register (see page 1127). The timer is configured to count up or down using the T_nCDIR bit in the **GPTMTnMR** register.

When software sets the T_nEN bit in the **GPTM Control (GPTMCTL)** register (see page 1136), the timer begins counting up from 0x0 or down from its preloaded value. Alternatively, if the T_nWOT bit is set in the **GPTMTnMR** register, once the T_nEN bit is set, the timer waits for a trigger to begin counting (see “Wait-for-Trigger Mode” on page 1118). Table 16-4 on page 1109 shows the values that are loaded into the timer registers when the timer is enabled.

Table 16-4. Counter Values When the Timer is Enabled in Periodic or One-Shot Modes

| Register | Count Down Mode | Count Up Mode |
|-----------------|--|--|
| GPTMTnR | GPTMTnILR | 0x0 |
| GPTMTnV | GPTMTnILR in concatenated mode; GPTMTnPR in combination with GPTMTnILR in individual mode | 0x0 |
| GPTMTnPS | GPTMTnPR in individual mode; not available in concatenated mode | 0x0 in individual mode; not available in concatenated mode |

When the timer is counting down and it reaches the timeout event (0x0), the timer reloads its start value from the **GPTMTnILR** and the **GPTMTnPR** registers on the next cycle. When the timer is counting up and it reaches the timeout event (the value in the **GPTMTnILR** and the optional

GPTMTnPR registers), the timer reloads with 0x0. If configured to be a one-shot timer, the timer stops counting and clears the **TnEN** bit in the **GPTMCTL** register. If configured as a periodic timer, the timer starts counting again on the next cycle.

In periodic, snap-shot mode (**TnMR** field is 0x2 and the **TnSNAPS** bit is set in the **GPTMTnMR** register), the value of the timer at the time-out event is loaded into the **GPTMTnR** register and the value of the prescaler is loaded into the **GPTMTnPS** register. The free-running counter value is shown in the **GPTMTnV** register. In this manner, software can determine the time elapsed from the interrupt assertion to the ISR entry by examining the snapshot values and the current value of the free-running timer. Snapshot mode is not available when the timer is configured in one-shot mode.

In addition to reloading the count value, the GPTM can generate interrupts, CCP outputs and triggers when it reaches the time-out event. The GPTM sets the **TnTORIS** bit in the **GPTM Raw Interrupt Status (GPTMRIS)** register (see page 1146), and holds it until it is cleared by writing the **GPTM Interrupt Clear (GPTMICR)** register (see page 1152). If the time-out interrupt is enabled in the **GPTM Interrupt Mask (GPTMIMR)** register (see page 1143), the GPTM also sets the **TnTOMIS** bit in the **GPTM Masked Interrupt Status (GPTMMIS)** register (see page 1149). The time-out interrupt can be disabled entirely by setting the **TnCINTD** bit in the **GPTM Timer n Mode (GPTMTnMR)** register. In this case, the **TnTORIS** bit does not even set in the **GPTMRIS** register.

By setting the **TnMIE** bit in the **GPTMTnMR** register, an interrupt condition can also be generated when the Timer value equals the value loaded into the **GPTM Timer n Match (GPTMTnMATCHR)** and **GPTM Timer n Prescale Match (GPTMTnPMR)** registers. This interrupt has the same status, masking, and clearing functions as the time-out interrupt, but uses the match interrupt bits instead (for example, the raw interrupt status is monitored via **TnMRIS** bit in the **GPTM Raw Interrupt Status (GPTMRIS)** register). Note that the interrupt status bits are not updated by the hardware unless the **TnMIE** bit in the **GPTMTnMR** register is set, which is different than the behavior for the time-out interrupt. The ADC trigger is enabled by setting the **TnOTE** bit in **GPTMCTL** and the event that activates the ADC is configured in the **GPTM ADC Event (GPTMADCEV)** register. The μ DMA trigger is enabled by configuring and enabling the appropriate μ DMA channel as well as the type of trigger enable in the **GPTM DMA Event (GPTMDMAEV)** register. See “Channel Configuration” on page 713.

The **TnCACT** field of the **GPTM Timer n Mode (GPTMTnMR)** register can be configured to clear, set or toggle an output on a time-out event.

If software updates the **GPTMTnILR** or the **GPTMTnPR** register while the counter is counting down, the counter loads the new value on the next clock cycle and continues counting from the new value if the **TnILD** bit in the **GPTMTnMR** register is clear. If the **TnILD** bit is set, the counter loads the new value after the next timeout. If software updates the **GPTMTnILR** or the **GPTMTnPR** register while the counter is counting up, the timeout event is changed on the next cycle to the new value. If software updates the **GPTM Timer n Value (GPTMTnV)** register while the counter is counting up or down, the counter loads the new value on the next clock cycle and continues counting from the new value. If software updates the **GPTMTnMATCHR** or the **GPTMTnPMR** registers, the new values are reflected on the next clock cycle if the **TnMRSU** bit in the **GPTMTnMR** register is clear. If the **TnMRSU** bit is set, the new value will not take effect until the next timeout.

If the **TnSTALL** bit in the **GPTMCTL** register is set and the **RTCEN** bit is not set in the **GPTMCTL** register, the timer freezes counting while the processor is halted by the debugger. The timer resumes counting when the processor resumes execution. If the **RTCEN** bit is set, it prevents the **TnSTALL** bit from freezing the count when the processor is halted by the debugger.

The following table shows a variety of configurations for a 16-bit free-running timer while using the prescaler. All values assume a 120-MHz clock with $T_c=8.33$ ns (clock period). The prescaler can only be used when a 16/32-bit timer is configured in 16-bit mode.

Table 16-5. 16-Bit Timer With Prescaler Configurations

| Prescale (8-bit value) | # of Timer Clocks (Tc) ^a | Max Time | Units |
|------------------------|-------------------------------------|----------|-------|
| 00000000 | 1 | 0.548258 | ms |
| 00000001 | 2 | 1.096517 | ms |
| 00000010 | 3 | 1.644775 | ms |
| ----- | -- | -- | -- |
| 11111101 | 254 | 139.2576 | ms |
| 11111110 | 255 | 139.8059 | ms |
| 11111111 | 256 | 140.3541 | ms |

a. Tc is the clock period.

Timer Compare Action Mode

The timer compare mode is an extension to the GPTM's existing one-shot and periodic modes. This mode can be used when an application requires a pin change state at some time in the future, regardless of the processor state. The compare mode does not operate when the PWM mode is active and is mutually exclusive to the PWM mode. The compare mode is enabled when the TAMR field is set to 0x1 or 0x2 (one-shot or periodic), the TnAMS bit is 0 (capture or compare mode) and the TCACT field is nonzero in the **GPTM Timer n Mode (GPTMTnMR)** register. Depending on the TCACT encoding, the timer can perform a set, clear or toggle on the corresponding CCPn pin when a timer match occurs. In 16-bit mode, the corresponding CCP pin can have an action applied, but when operating in 32-bit mode, the action can only be applied to the even CCP pin.

The TCACT field can be changed while the GPTM is enabled to generate different combinations of actions. For example, during a periodic event, encodings TCACT = 0x6 or 0x7 can be used to force the initial state of the CCPn pin before the first interrupt and following that, TCACT=0x2 and TCACT=0x3 can be used (alternately) to change the sense of the pin for the subsequent toggle, while possible changing load value for the next period.

The time-out interrupts used for one-shot and periodic modes are used in the compare action modes. Thus, the TnTORIS bits in the **GPTMRIS** register are triggered if the appropriate mask bits are set in the **GPTMIM** register.

16.3.3.2 Real-Time Clock Timer Mode

In Real-Time Clock (RTC) mode, the concatenated versions of the Timer A and Timer B registers are configured as an up-counter. When RTC mode is selected for the first time after reset, the counter is loaded with a value of 0x1. All subsequent load values must be written to the **GPTM Timer n Interval Load (GPTMTnILR)** registers (see page 1154). If the **GPTMTnILR** register is loaded with a new value, the counter begins counting at that value and rolls over at the fixed value of 0xFFFFFFFF. Table 16-6 on page 1111 shows the values that are loaded into the timer registers when the timer is enabled.

Table 16-6. Counter Values When the Timer is Enabled in RTC Mode

| Register | Count Down Mode | Count Up Mode |
|----------|-----------------|---------------|
| GPTMTnR | Not available | 0x1 |
| GPTMTnV | Not available | 0x1 |
| GPTMTnPS | Not available | Not available |

The input clock on a CCP0 input is required to be 32.768 KHz in RTC mode. The clock signal is then divided down to a 1-Hz rate and is passed along to the input of the counter.

When software writes the **TAEN** bit in the **GPTMCTL** register, the counter starts counting up from its preloaded value of 0x1. When the current count value matches the preloaded value in the **GPTMTnMATCHR** registers, the GPTM asserts the **RTC RIS** bit in **GPTMRIS** and continues counting until either a hardware reset, or it is disabled by software (clearing the **TAEN** bit). When the timer value reaches the terminal count, the timer rolls over and continues counting up from 0x0. If the RTC interrupt is enabled in **GPTMIMR**, the GPTM also sets the **RTCMIS** bit in **GPTMMIS** and generates a controller interrupt. The status flags are cleared by writing the **RTCCINT** bit in **GPTMICR**.

In this mode, the **GPTMTnR** and **GPTMTnV** registers always have the same value.

In addition to generating interrupts, the RTC can generate a μ DMA trigger. The μ DMA trigger is enabled by configuring and enabling the appropriate μ DMA channel as well as the type of trigger enable in the **GPTM DMA Event (GPTMDMAEV)** register. See “Channel Configuration” on page 713.

16.3.3.3 Input Edge-Count Mode

Note: For rising-edge detection, the input signal must be High for at least two clock periods following the rising edge. Similarly, for falling-edge detection, the input signal must be Low for at least two clock periods following the falling edge. Based on this criteria, the maximum input frequency for edge detection is 1/4 of the frequency.

In Edge-Count mode, the timer is configured as a 24-bit up- or down-counter including the optional prescaler with the upper count value stored in the **GPTM Timer n Prescale (GPTMTnPR)** register and the lower bits in the **GPTMTnR** register. In this mode, the timer is capable of capturing three types of events: rising edge, falling edge, or both. To place the timer in Edge-Count mode, the **TnCMR** bit of the **GPTMTnMR** register must be cleared. The type of edge that the timer counts is determined by the **TnEVENT** fields of the **GPTMCTL** register. During initialization in down-count mode, the **GPTMTnMATCHR** and **GPTMTnPMR** registers are configured so that the difference between the value in the **GPTMTnILR** and **GPTMTnPR** registers and the **GPTMTnMATCHR** and **GPTMTnPMR** registers equals the number of edge events that must be counted. In up-count mode, the timer counts from 0x0 to the value in the **GPTMTnMATCHR** and **GPTMTnPMR** registers. Note that when executing an up-count, that the value of **GPTMTnPR** and **GPTMTnILR** must be greater than the value of **GPTMTnPMR** and **GPTMTnMATCHR**. Table 16-7 on page 1112 shows the values that are loaded into the timer registers when the timer is enabled.

Table 16-7. Counter Values When the Timer is Enabled in Input Edge-Count Mode

| Register | Count Down Mode | Count Up Mode |
|----------------|--|---------------|
| GPTMTnR | GPTMTnPR in combination with GPTMTnILR | 0x0 |
| GPTMTnV | GPTMTnPR in combination with GPTMTnILR | 0x0 |

When software writes the **TnEN** bit in the **GPTM Control (GPTMCTL)** register, the timer is enabled for event capture. Each input event on the CCP pin decrements or increments the counter by 1 until the event count matches **GPTMTnMATCHR** and **GPTMTnPMR**. When the counts match, the GPTM asserts the **CnMRIS** bit in the **GPTM Raw Interrupt Status (GPTMRIS)** register, and holds it until it is cleared by writing the **GPTM Interrupt Clear (GPTMICR)** register. If the capture mode match interrupt is enabled in the **GPTM Interrupt Mask (GPTMIMR)** register, the GPTM also sets the **CnMMIS** bit in the **GPTM Masked Interrupt Status (GPTMMIS)** register. In up-count mode, the current count of the input events is held in both the **GPTMTnR** and **GPTMTnV** registers. In down-count mode, the current count of the input events can be obtained by subtracting the **GPTMTnR** or **GPTMTnV** from the value made up of the **GPTMTnPR** and **GPTMTnILR** register combination.

In addition to generating interrupts, an ADC and/or a μ DMA trigger can be generated. The ADC trigger is enabled by setting the **TnOTE** bit in **GPTMCTL** and the event that activates the ADC is configured in the **GPTM ADC Event (GPTMADCEV)** register. The μ DMA trigger is enabled by

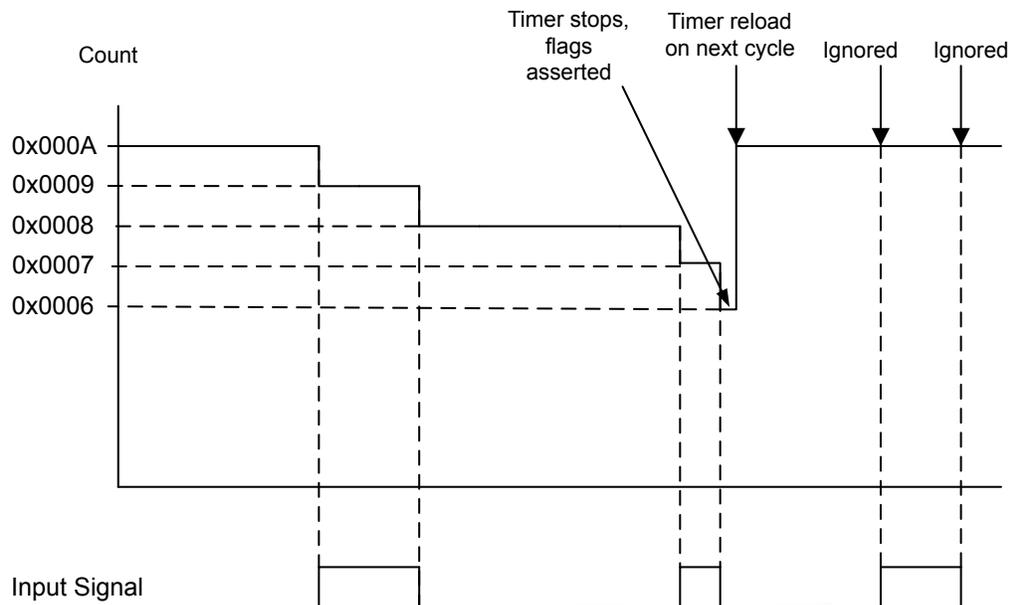

configuring and enabling the appropriate μ DMA channel as well as the type of trigger enable in the **GPTM DMA Event (GPTMDMAEV)** register. See “Channel Configuration” on page 713.

After the match value is reached in down-count mode, the counter is then reloaded using the value in **GPTMTnILR** and **GPTMTnPR** registers, and stopped because the GPTM automatically clears the **TnEN** bit in the **GPTMCTL** register. Once the event count has been reached, all further events are ignored until **TnEN** is re-enabled by software. In up-count mode, the timer is reloaded with 0x0 and continues counting.

Figure 16-2 on page 1113 shows how Input Edge-Count mode works. In this case, the timer start value is set to **GPTMTnILR** = 0x000A and the match value is set to **GPTMTnMATCHR** = 0x0006 so that four edge events are counted. The counter is configured to detect both edges of the input signal.

Note that the last two edges are not counted because the timer automatically clears the **TnEN** bit after the current count matches the value in the **GPTMTnMATCHR** register.

Figure 16-2. Input Edge-Count Mode Example, Counting Down

16.3.3.4 Input Edge-Time Mode

Note: For rising-edge detection, the input signal must be High for at least two system clock periods following the rising edge. Similarly, for falling edge detection, the input signal must be Low for at least two system clock periods following the falling edge. Based on this criteria, the maximum input frequency for edge detection is 1/4 of the system frequency.

In Edge-Time mode, the timer is configured as a 24-bit up- or down-counter including the optional prescaler with the upper timer value stored in the **GPTMTnPR** register and the lower bits in the **GPTMTnILR** register. In this mode, the timer is initialized to the value loaded in the **GPTMTnILR** and **GPTMTnPR** registers when counting down and 0x0 when counting up. The timer is capable of capturing three types of events: rising edge, falling edge, or both. The timer is placed into Edge-Time mode by setting the **TnCMR** bit in the **GPTMTnMR** register, and the type of event that the timer captures is determined by the **TnEVENT** fields of the **GPTMCTL** register. Table 16-8 on page 1114 shows the values that are loaded into the timer registers when the timer is enabled.

Table 16-8. Counter Values When the Timer is Enabled in Input Event-Count Mode

| Register | Count Down Mode | Count Up Mode |
|----------|-----------------|---------------|
| TnR | GPTMTnILR | 0x0 |
| TnV | GPTMTnILR | 0x0 |

When software writes the TnEN bit in the **GPTMCTL** register, the timer is enabled for event capture. When the selected input event is detected, the current timer counter value is captured in the **GPTMTnR** and **GPTMTnPS** register and is available to be read by the microcontroller. The GPTM then asserts the CnERIS bit in the **GPTM Raw Interrupt Status (GPTMRIS)** register, and holds it until it is cleared by writing the **GPTM Interrupt Clear (GPTMICR)** register. If the capture mode event interrupt is enabled in the **GPTM Interrupt Mask (GPTMIMR)** register, the GPTM also sets the CnEMIS bit in the **GPTM Masked Interrupt Status (GPTMMIS)** register. In this mode, the **GPTMTnR** and **GPTMTnPS** registers hold the time at which the selected input event occurred while the **GPTMTnV** register holds the free-running timer value. These registers can be read to determine the time that elapsed between the interrupt assertion and the entry into the ISR.

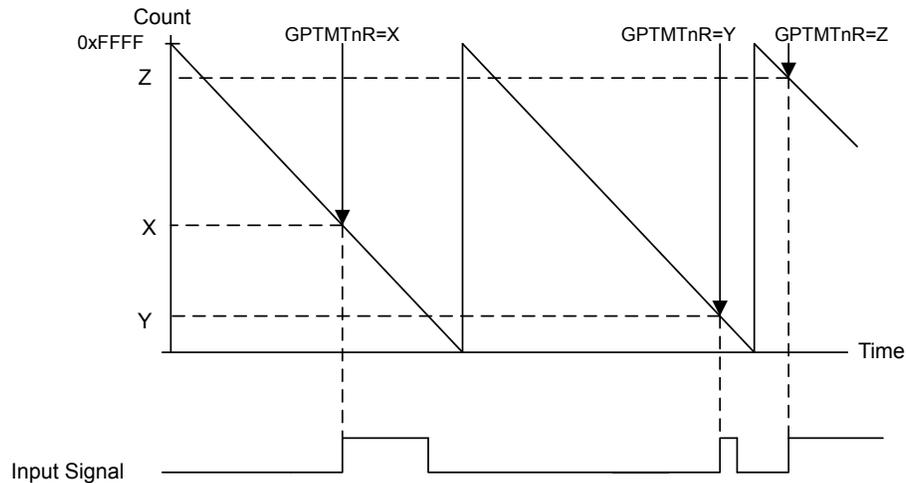

In addition to generating interrupts, an ADC and/or a μ DMA trigger can be generated. The ADC trigger is enabled by setting the TnOTE bit in **GPTMCTL** and the event that activates the ADC is configured in the **GPTM ADC Event (GPTMADCEV)** register. The μ DMA trigger is enabled by configuring the appropriate μ DMA channel as well as the type of trigger selected in the **GPTM DMA Event (GPTMDMAEV)** register. See “Channel Configuration” on page 713.

After an event has been captured, the timer does not stop counting. It continues to count until the TnEN bit is cleared. When the timer reaches the timeout value, it is reloaded with 0x0 in up-count mode and the value from the **GPTMTnILR** and **GPTMTnPR** registers in down-count mode.

Figure 16-3 on page 1115 shows how input edge timing mode works. In the diagram, it is assumed that the start value of the timer is the default value of 0xFFFF, and the timer is configured to capture rising edge events.

Each time a rising edge event is detected, the current count value is loaded into the **GPTMTnR** and **GPTMTnPS** registers, and is held there until another rising edge is detected (at which point the new count value is loaded into the **GPTMTnR** and **GPTMTnPS** registers).

Figure 16-3. 16-Bit Input Edge-Time Mode Example

Note: When operating in Edge-time mode, the counter uses a modulo 2^{24} count if prescaler is enabled or 2^{16} , if not. If there is a possibility the edge could take longer than the count, then another timer configured in periodic-timer mode can be implemented to ensure detection of the missed edge. The periodic timer should be configured in such a way that:

- The periodic timer cycles at the same rate as the edge-time timer
- The periodic timer interrupt has a higher interrupt priority than the edge-time timeout interrupt.
- If the periodic timer interrupt service routine is entered, software must check if an edge-time interrupt is pending and if it is, the value of the counter must be subtracted by 1 before being used to calculate the snapshot time of the event.

16.3.3.5 PWM Mode

The GPTM supports a simple PWM generation mode. In PWM mode, the timer is configured as a 24-bit down-counter with a start value (and thus period) defined by the **GPTMTnILR** and **GPTMTnPR** registers. In this mode, the PWM frequency and period are synchronous events and therefore guaranteed to be glitch free. PWM mode is enabled with the **GPTMTnMR** register by setting the **TnAMS** bit to 0x1, the **TnCMR** bit to 0x0, and the **TnMR** field to 0x2. Table 16-9 on page 1115 shows the values that are loaded into the timer registers when the timer is enabled.

Table 16-9. Counter Values When the Timer is Enabled in PWM Mode

| Register | Count Down Mode | Count Up Mode |
|----------------|------------------|---------------|
| GPTMTnR | GPTMTnILR | Not available |
| GPTMTnV | GPTMTnILR | Not available |

When software writes the **TnEN** bit in the **GPTMCTL** register, the counter begins counting down until it reaches the 0x0 state. Alternatively, if the **TnWOT** bit is set in the **GPTMTnMR** register, once the **TnEN** bit is set, the timer waits for a trigger to begin counting (see “Wait-for-Trigger

Mode” on page 1118). On the next counter cycle in periodic mode, the counter reloads its start value from the **GPTMTnILR** and **GPTMTnPR** registers and continues counting until disabled by software clearing the **TnEN** bit in the **GPTMCTL** register. The timer is capable of generating interrupts based on three types of events: rising edge, falling edge, or both. The event is configured by the **TnEVENT** field of the **GPTMCTL** register, and the interrupt is enabled by setting the **TnPWMIE** bit in the **GPTMTnMR** register. When the event occurs, the **CnERIS** bit is set in the **GPTM Raw Interrupt Status (GPTMRIS)** register, and holds it until it is cleared by writing the **GPTM Interrupt Clear (GPTMICR)** register. If the capture mode event interrupt is enabled in the **GPTM Interrupt Mask (GPTMIMR)** register, the GPTM also sets the **CnEMIS** bit in the **GPTM Masked Interrupt Status (GPTMMIS)** register. Note that the interrupt status bits are not updated unless the **TnPWMIE** bit is set.

In addition, when the **TnPWMIE** bit is set and a capture event occurs, the Timer automatically generates triggers to the ADC and DMA if the trigger capability is enabled by setting the **TnOTE** bit in the **GPTMCTL** register and the **CnEDMAEN** bit in the **GPTMDMAEV** register, respectively.

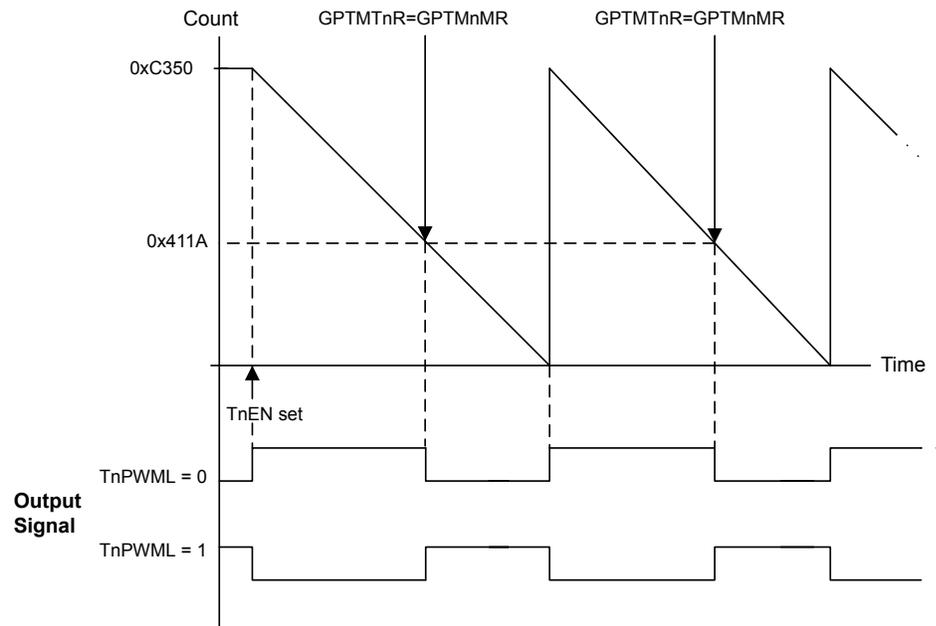

In this mode, the **GPTMTnR** and **GPTMTnV** registers always have the same value.

The output PWM signal asserts when the counter is at the value of the **GPTMTnILR** and **GPTMTnPR** registers (its start state), and is deasserted when the counter value equals the value in the **GPTMTnMATCHR** and **GPTMTnPMR** registers. Software has the capability of inverting the output PWM signal by setting the **TnPWML** bit in the **GPTMCTL** register.

Note: If PWM output inversion is enabled, edge detection interrupt behavior is reversed. Thus, if a positive-edge interrupt trigger has been set and the PWM inversion generates a positive edge, no event-trigger interrupt asserts. Instead, the interrupt is generated on the negative edge of the PWM signal.

Figure 16-4 on page 1117 shows how to generate an output PWM with a 1-ms period and a 66% duty cycle assuming a 50-MHz input clock and **TnPWML** = 0 (duty cycle would be 33% for the **TnPWML** = 1 configuration). For this example, the start value is **GPTMTnILR**=0xC350 and the match value is **GPTMTnMATCHR**=0x411A.

Figure 16-4. 16-Bit PWM Mode Example

When synchronizing the timers using the **GPTMSYNC** register, the timer must be properly configured to avoid glitches on the CCP outputs. Both the **TnPLO** and the **TnMRSU** bits must be set in the **GPTMTnMR** register. Figure 16-5 on page 1117 shows how the CCP output operates when the **TnPLO** and **TnMRSU** bits are set and the **GPTMTnMATCHR** value is greater than the **GPTMTnILR** value.

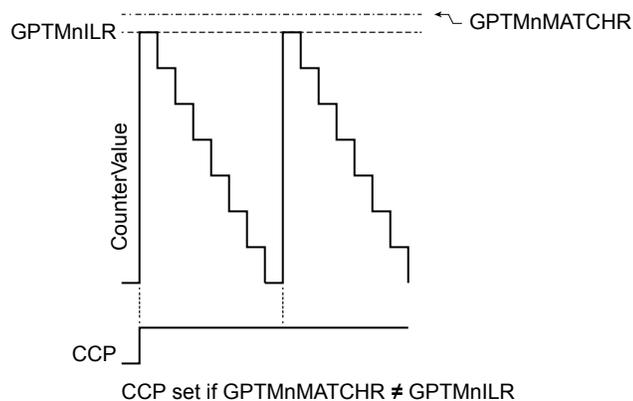

Figure 16-5. CCP Output, **GPTMTnMATCHR** > **GPTMTnILR**

Figure 16-6 on page 1118 shows how the CCP output operates when the **PLO** and **MRSU** bits are set and the **GPTMTnMATCHR** value is the same as the **GPTMTnILR** value. In this situation, if the **PLO** bit is 0, the CCP signal goes high when the **GPTMTnILR** value is loaded and the match would be essentially ignored.

Figure 16-6. CCP Output, GPTMTnMATCHR = GPTMTnILR

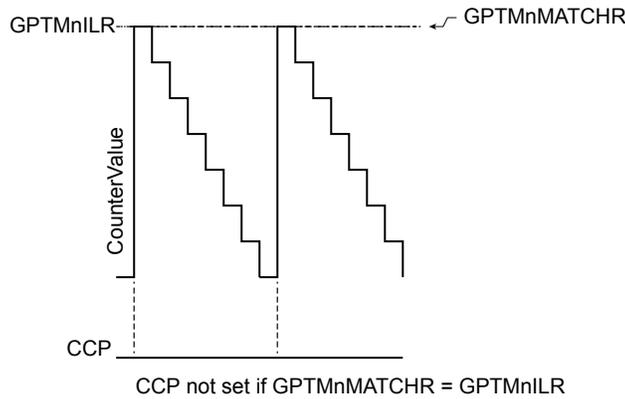

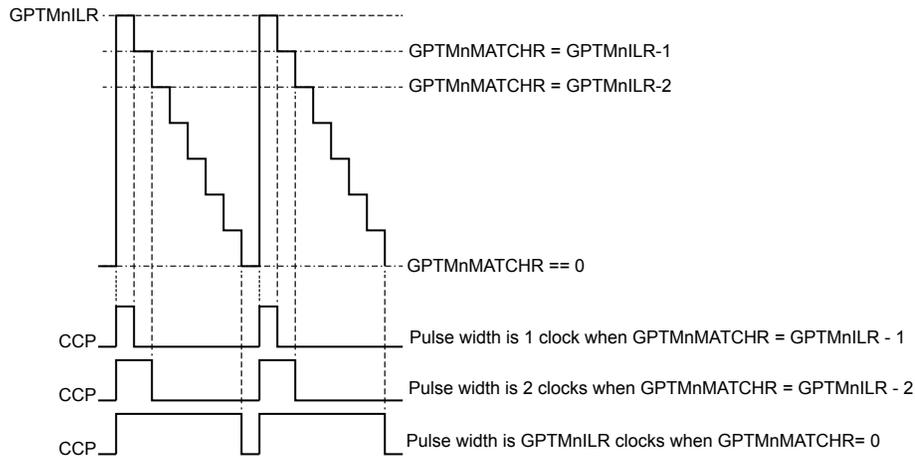

Figure 16-7 on page 1118 shows how the CCP output operates when the `PLO` and `MRSU` bits are set and the `GPTMTnILR` is greater than the `GPTMTnMATCHR` value.

Figure 16-7. CCP Output, GPTMTnILR > GPTMTnMATCHR

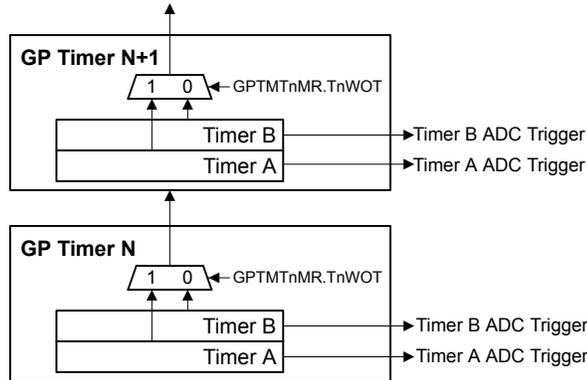

16.3.4 Wait-for-Trigger Mode

The Wait-for-Trigger mode allows daisy chaining of the timer modules such that once configured, a single timer can initiate multiple timing events using the Timer triggers. Wait-for-Trigger mode is enabled by setting the `TnWOT` bit in the `GPTMTnMR` register. When the `TnWOT` bit is set, Timer N+1 does not begin counting until the timer in the previous position in the daisy chain (Timer N) reaches its time-out event. The daisy chain is configured such that GPTM1 always follows GPTM0, GPTM2 follows GPTM1, and so on. If Timer A is configured as a 32-bit (16/32-bit mode) timer (controlled by the `GPTMCFG` field in the `GPTMCFG` register), it triggers Timer A in the next module. If Timer A is configured as a 16-bit (16/32-bit mode) timer, it triggers Timer B in the same module, and Timer B triggers Timer A in the next module. Figure 16-8 on page 1119 shows how the `GPTMCFG` bit affects the daisy chain. This function is valid for one-shot, periodic, and PWM modes.

Note: If the application requires cyclical daisy-chaining, the `TAWOT` bit in the `GPTMTAMR` register of Timer 0 can be set. In this case, Timer 0 waits for a trigger from the last timer module in the chain.

Figure 16-8. Timer Daisy Chain

16.3.5 Synchronizing GP Timer Blocks

The **GPTM Synchronizer Control (GPTMSYNC)** register in the GPTM0 block can be used to synchronize selected timers to begin counting at the same time. Setting a bit in the **GPTMSYNC** register causes the associated timer to perform the actions of a timeout event. An interrupt is not generated when the timers are synchronized. If a timer is being used in concatenated mode, only the bit for Timer A must be set in the **GPTMSYNC** register.

Note: All timers must use the same clock source for this feature to work correctly.

Table 16-10 on page 1119 shows the actions for the timeout event performed when the timers are synchronized in the various timer modes.

Table 16-10. Timeout Actions for GPTM Modes

| Mode | Count Dir | Time Out Action |
|--|-----------|-------------------|
| 32-bit One-Shot (concatenated timers) | — | N/A |
| 32-bit Periodic (concatenated timers) | Down | Count value = ILR |
| | Up | Count value = 0 |
| 32-bit RTC (concatenated timers) | Up | Count value = 0 |
| 16-bit One Shot (individual/split timers) | — | N/A |
| 16-bit Periodic (individual/split timers) | Down | Count value = ILR |
| | Up | Count value = 0 |
| 16-bit Edge-Count (individual/split timers) | Down | Count value = ILR |
| | Up | Count value = 0 |
| 16-bit Edge-Time (individual/split timers) | Down | Count value = ILR |
| | Up | Count value = 0 |
| 16-bit PWM | Down | Count value = ILR |

16.3.6 DMA Operation

The timers each have a dedicated μ DMA channel and can provide a request signal to the μ DMA controller. Pulse requests are generated by a timer via its own `dma_req` signal. A `dma_done` signal is provided from the μ DMA to each timer to indicate transfer completion and trigger a μ DMA done interrupt (`DMAnRIS`) in the **GPTM Raw Interrupt Status Register (GPTMRIS) register**. The request is a burst type and occurs whenever a timer raw interrupt condition occurs. The arbitration size of the μ DMA transfer should be set to the amount of data that should be transferred whenever a timer event occurs.

For example, to transfer 256 items, 8 items at a time every 10 ms, configure a timer to generate a periodic timeout at 10 ms. Configure the μ DMA transfer for a total of 256 items, with a burst size of 8 items. Each time the timer times out, the μ DMA controller transfers 8 items, until all 256 items have been transferred. Refer to “Micro Direct Memory Access (μ DMA)” on page 708 for more details about programming the μ DMA controller.

A **GPTM DMA Event (GPTMDMAEV) register** is provided to enable the types of events that can cause a `dma_req` signal assertion by the timer module. Application software can enable a `dma_req` trigger for a match, capture or time-out event for each timer using the **GPTMDMAEV register**. For an individual timer, all active timer trigger events that have been enabled through the **GPTMDMAEV register** are ORed together to create a single `dma_req` pulse that is sent to the μ DMA. When the μ DMA transfer has completed, a `dma_done` signal is sent to the timer resulting in a `DMAnRIS` bit set in the **GPTMRIS register**.

16.3.7 ADC Operation

The timer has the capability to trigger the ADC when the `TnOTE` bit is set in the **GPTMCTL register** at offset 0x00C. The **GPTM ADC Event (GPTMADCEV) register** is additionally provided so that the type of ADC trigger can be defined. For example, by setting the `CBMADCEN` bit in the **GPTMADCEV register**, a trigger pulse will be sent to the ADC whenever a Capture Match event occurs in GPTM B. Similar to the μ DMA operation, all active trigger events that have also been enabled in the **GPTMADCEV register** are ORed together to create an ADC trigger pulse.

16.3.8 Accessing Concatenated 16/32-Bit GPTM Register Values

The GPTM is placed into concatenated mode by writing a 0x0 or a 0x1 to the `GPTMCFG` bit field in the **GPTM Configuration (GPTMCFG) register**. In both configurations, certain 16/32-bit GPTM registers are concatenated to form pseudo 32-bit registers. These registers include:

- **GPTM Timer A Interval Load (GPTMTAILR) register** [15:0], see page 1154
- **GPTM Timer B Interval Load (GPTMTBILR) register** [15:0], see page 1155
- **GPTM Timer A (GPTMTAR) register** [15:0], see page 1162
- **GPTM Timer B (GPTMTBR) register** [15:0], see page 1163
- **GPTM Timer A Value (GPTMTAV) register** [15:0], see page 1164
- **GPTM Timer B Value (GPTMTBV) register** [15:0], see page 1165
- **GPTM Timer A Match (GPTMTAMATCHR) register** [15:0], see page 1156
- **GPTM Timer B Match (GPTMTBMATCHR) register** [15:0], see page 1157

In the 32-bit modes, the GPTM translates a 32-bit write access to **GPTMTAILR** into a write access to both **GPTMTAILR** and **GPTMTBILR**. The resulting word ordering for such a write operation is:

```
GPTMTBILR[15:0]:GPTMTAILR[15:0]
```

Likewise, a 32-bit read access to **GPTMTAR** returns the value:

```
GPTMTBR[15:0]:GPTMTAR[15:0]
```

A 32-bit read access to **GPTMTAV** returns the value:

```
GPTMTBV[15:0]:GPTMTAV[15:0]
```

16.4 Initialization and Configuration

To use a GPTM, the appropriate **TIMERN** bit must be set in the **RCGCTIMER** register (see page 397). If using any CCP pins, the clock to the appropriate GPIO module must be enabled via the **RCGCGPIO** register (see page 399). To find out which GPIO port to enable, refer to Table 31-4 on page 2064. Configure the **PMCn** fields in the **GPIOPCTL** register to assign the CCP signals to the appropriate pins (see page 820 and Table 31-5 on page 2081).

This section shows module initialization and configuration examples for each of the supported timer modes.

16.4.1 One-Shot/Periodic Timer Mode

The GPTM is configured for One-Shot and Periodic modes by the following sequence:

1. Ensure the timer is disabled (the **TnEN** bit in the **GPTMCTL** register is cleared) before making any changes.
2. Write the **GPTM Configuration Register (GPTMCFG)** with a value of 0x0000.0000.
3. Configure the **TnMR** field in the **GPTM Timer n Mode Register (GPTMTnMR)**:
 - a. Write a value of 0x1 for One-Shot mode.
 - b. Write a value of 0x2 for Periodic mode.
4. Optionally configure the **TnSNAPS**, **TnWOT**, **TnMTE**, and **TnCDIR** bits in the **GPTMTnMR** register to select whether to capture the value of the free-running timer at time-out, use an external trigger to start counting, configure an additional trigger or interrupt, and count up or down. In addition, if using CCP pins, the **TnCACT** field can be programmed to configure the compare action.
5. Load the start value into the **GPTM Timer n Interval Load Register (GPTMTnILR)**.
6. If interrupts are required, set the appropriate bits in the **GPTM Interrupt Mask Register (GPTMIMR)**.
7. Set the **TnEN** bit in the **GPTMCTL** register to enable the timer and start counting.
8. Poll the **GPTMRIS** register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the appropriate bit of the **GPTM Interrupt Clear Register (GPTMICR)**.

If the `TnMIE` bit in the **GPTMTnMR** register is set, the `RTCRES` bit in the **GPTMRIS** register is set, and the timer continues counting. In One-Shot mode, the timer stops counting after the time-out event. To re-enable the timer, repeat the sequence. A timer configured in Periodic mode reloads the timer and continues counting after the time-out event.

16.4.2 Real-Time Clock (RTC) Mode

To use the RTC mode, the timer must have a 32.768-KHz input signal on an even CCP input. To enable the RTC feature, follow these steps:

1. Ensure the timer is disabled (the `TAEN` bit is cleared) before making any changes.
2. If the timer has been operating in a different mode prior to this, clear any residual set bits in the **GPTM Timer n Mode (GPTMTnMR)** register before reconfiguring.
3. Write the **GPTM Configuration Register (GPTMCFG)** with a value of `0x0000.0001`.
4. Write the match value to the **GPTM Timer n Match Register (GPTMTnMATCHR)**.
5. Set/clear the `RTCEN` and `TnSTALL` bit in the **GPTM Control Register (GPTMCTL)** as needed.
6. If interrupts are required, set the `RTCIM` bit in the **GPTM Interrupt Mask Register (GPTMIMR)**.
7. Set the `TAEN` bit in the **GPTMCTL** register to enable the timer and start counting.

When the timer count equals the value in the **GPTMTnMATCHR** register, the GPTM asserts the `RTCRES` bit in the **GPTMRIS** register and continues counting until Timer A is disabled or a hardware reset. The interrupt is cleared by writing the `RTCCINT` bit in the **GPTMICR** register. Note that if the **GPTMTnILR** register is loaded with a new value, the timer begins counting at this new value and continues until it reaches `0xFFFF.FFFF`, at which point it rolls over.

16.4.3 Input Edge-Count Mode

A timer is configured to Input Edge-Count mode by the following sequence:

1. Ensure the timer is disabled (the `TnEN` bit is cleared) before making any changes.
2. Write the **GPTM Configuration (GPTMCFG)** register with a value of `0x0000.0004`.
3. In the **GPTM Timer Mode (GPTMTnMR)** register, write the `TnCMR` field to `0x0` and the `TnMR` field to `0x3`.
4. Configure the type of event(s) that the timer captures by writing the `TnEVENT` field of the **GPTM Control (GPTMCTL)** register.
5. Program registers according to count direction:
 - In down-count mode, the **GPTMTnMATCHR** and **GPTMTnPMR** registers are configured so that the difference between the value in the **GPTMTnILR** and **GPTMTnPR** registers and the **GPTMTnMATCHR** and **GPTMTnPMR** registers equals the number of edge events that must be counted.
 - In up-count mode, the timer counts from `0x0` to the value in the **GPTMTnMATCHR** and **GPTMTnPMR** registers. Note that when executing an up-count, the value of the **GPTMTnPR** and **GPTMTnILR** must be greater than the value of **GPTMTnPMR** and **GPTMTnMATCHR**.

6. If interrupts are required, set the `CnMIM` bit in the **GPTM Interrupt Mask (GPTMIMR)** register.
7. Set the `TnEN` bit in the **GPTMCTL** register to enable the timer and begin waiting for edge events.
8. Poll the `CnMRIS` bit in the **GPTMRIS** register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the `CnMCINT` bit of the **GPTM Interrupt Clear (GPTMICR)** register.

When counting down in Input Edge-Count Mode, the timer stops after the programmed number of edge events has been detected. To re-enable the timer, ensure that the `TnEN` bit is cleared and repeat steps 4 through 8.

16.4.4 Input Edge Time Mode

A timer is configured to Input Edge Time mode by the following sequence:

1. Ensure the timer is disabled (the `TnEN` bit is cleared) before making any changes.
2. Write the **GPTM Configuration (GPTMCFG)** register with a value of 0x0000.0004.
3. In the **GPTM Timer Mode (GPTMTnMR)** register, write the `TnCMR` field to 0x1 and the `TnMR` field to 0x3 and select a count direction by programming the `TnCDIR` bit.
4. Configure the type of event that the timer captures by writing the `TnEVENT` field of the **GPTM Control (GPTMCTL)** register.
5. If a prescaler is to be used, write the prescale value to the **GPTM Timer n Prescale Register (GPTMTnPR)**.
6. Load the timer start value into the **GPTM Timer n Interval Load (GPTMTnILR)** register.
7. If interrupts are required, set the `CnEIM` bit in the **GPTM Interrupt Mask (GPTMIMR)** register.
8. Set the `TnEN` bit in the **GPTM Control (GPTMCTL)** register to enable the timer and start counting.
9. Poll the `CnERIS` bit in the **GPTMRIS** register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the `CnECINT` bit of the **GPTM Interrupt Clear (GPTMICR)** register. The time at which the event happened can be obtained by reading the **GPTM Timer n (GPTMTnR)** register.

In Input Edge Timing mode, the timer continues running after an edge event has been detected, but the timer interval can be changed at any time by writing the **GPTMTnILR** register and clearing the `TnILD` bit in the **GPTMTnMR** register. The change takes effect at the next cycle after the write.

16.4.5 PWM Mode

A timer is configured to PWM mode using the following sequence:

1. Ensure the timer is disabled (the `TnEN` bit is cleared) before making any changes.
2. Write the **GPTM Configuration (GPTMCFG)** register with a value of 0x0000.0004.
3. In the **GPTM Timer Mode (GPTMTnMR)** register, set the `TnAMS` bit to 0x1, the `TnCMR` bit to 0x0, and the `TnMR` field to 0x2.

4. Configure the output state of the PWM signal (whether or not it is inverted) in the T_nPWML field of the **GPTM Control (GPTMCTL)** register.
5. If a prescaler is to be used, write the prescale value to the **GPTM Timer n Prescale Register (GPTMTnPR)**.
6. If PWM interrupts are used, configure the interrupt condition in the T_nEVENT field in the **GPTMCTL** register and enable the interrupts by setting the T_nPWMIE bit in the **GPTMTnMR** register. Note that edge detect interrupt behavior is reversed when the PWM output is inverted (see page 1136).
7. Load the timer start value into the **GPTM Timer n Interval Load (GPTMTnILR)** register.
8. Load the **GPTM Timer n Match (GPTMTnMATCHR)** register with the match value.
9. Set the T_nEN bit in the **GPTM Control (GPTMCTL)** register to enable the timer and begin generation of the output PWM signal.

In PWM Time mode, the timer continues running after the PWM signal has been generated. The PWM period can be adjusted at any time by writing the **GPTMTnILR** register, and the change takes effect at the next cycle after the write.

16.5 Register Map

Table 16-11 on page 1124 lists the GPTM registers. The offset listed is a hexadecimal increment to the register's address, relative to that timer's base address:

- 16/32-bit Timer 0: 0x4003.0000
- 16/32-bit Timer 1: 0x4003.1000
- 16/32-bit Timer 2: 0x4003.2000
- 16/32-bit Timer 3: 0x4003.3000
- 16/32-bit Timer 4: 0x4003.4000
- 16/32-bit Timer 5: 0x4003.5000
- 16/32-bit Timer 6: 0x400E.0000
- 16/32-bit Timer 7: 0x400E.1000

Note that the GP Timer module clock must be enabled before the registers can be programmed (see page 397). There must be a delay of 3 system clocks after the Timer module clock is enabled before any Timer module registers are accessed.

Table 16-11. Timers Register Map

| Offset | Name | Type | Reset | Description | See page |
|--------|----------|------|-------------|---------------------|----------|
| 0x000 | GPTMCFG | RW | 0x0000.0000 | GPTM Configuration | 1126 |

16.6 Register Descriptions

The remainder of this section lists and describes the GPTM registers, in numerical order by address offset.

Register 1: GPTM Configuration (GPTMCFG), offset 0x000

This register configures the global operation of the GPTM module. The value written to this register determines whether the GPTM is in 32- or 16-bit mode.

Important: Bits in this register should only be changed when the TAEN and TBEN bits in the GPTMCTL register are cleared.

GPTM Configuration (GPTMCFG)

16/32-bit Timer 0 base: 0x4003.0000
 16/32-bit Timer 1 base: 0x4003.1000
 16/32-bit Timer 2 base: 0x4003.2000
 16/32-bit Timer 3 base: 0x4003.3000
 16/32-bit Timer 4 base: 0x4003.4000
 16/32-bit Timer 5 base: 0x4003.5000
 16/32-bit Timer 6 base: 0x400E.0000
 16/32-bit Timer 7 base: 0x400E.1000
 Offset 0x000

| Bit/Field | Name | Type | Reset | Description | | | | | | | | | | | | |
|-----------|---|------|------------|---|-------|-------------|-----|---|-----|---|---------|----------|-----|---|---------|----------|
| 31:3 | reserved | RO | 0x0000.000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. | | | | | | | | | | | | |
| 2:0 | GPTMCFG | RW | 0x0 | GPTM Configuration The GPTMCFG values are defined as follows: <table border="0"> <tr> <td>Value</td> <td>Description</td> </tr> <tr> <td>0x0</td> <td>For a 16/32-bit timer, this value selects the 32-bit timer configuration.</td> </tr> <tr> <td>0x1</td> <td>For a 16/32-bit timer, this value selects the 32-bit real-time clock (RTC) counter configuration.</td> </tr> <tr> <td>0x2-0x3</td> <td>Reserved</td> </tr> <tr> <td>0x4</td> <td>For a 16/32-bit timer, this value selects the 16-bit timer configuration. The function is controlled by bits 1:0 of GPTMTAMR and GPTMTBMR.</td> </tr> <tr> <td>0x5-0x7</td> <td>Reserved</td> </tr> </table> | Value | Description | 0x0 | For a 16/32-bit timer, this value selects the 32-bit timer configuration. | 0x1 | For a 16/32-bit timer, this value selects the 32-bit real-time clock (RTC) counter configuration. | 0x2-0x3 | Reserved | 0x4 | For a 16/32-bit timer, this value selects the 16-bit timer configuration. The function is controlled by bits 1:0 of GPTMTAMR and GPTMTBMR. | 0x5-0x7 | Reserved |
| Value | Description | | | | | | | | | | | | | | | |
| 0x0 | For a 16/32-bit timer, this value selects the 32-bit timer configuration. | | | | | | | | | | | | | | | |
| 0x1 | For a 16/32-bit timer, this value selects the 32-bit real-time clock (RTC) counter configuration. | | | | | | | | | | | | | | | |
| 0x2-0x3 | Reserved | | | | | | | | | | | | | | | |
| 0x4 | For a 16/32-bit timer, this value selects the 16-bit timer configuration. The function is controlled by bits 1:0 of GPTMTAMR and GPTMTBMR. | | | | | | | | | | | | | | | |
| 0x5-0x7 | Reserved | | | | | | | | | | | | | | | |

Register 2: GPTM Timer A Mode (GPTMTAMR), offset 0x004

This register configures the GPTM based on the configuration selected in the **GPTMCFG** register. When in PWM mode, set the **TAAMS** bit, clear the **TACMR** bit, and configure the **TAMR** field to 0x1 or 0x2.

This register controls the modes for Timer A when it is used individually. When Timer A and Timer B are concatenated, this register controls the modes for both Timer A and Timer B, and the contents of **GPTMTBMR** are ignored.

Important: Except for the **TCACT** bit field, all other bits in this register should only be changed when the **TAEN** bit in the **GPTMCTL** register is cleared.

GPTM Timer A Mode (GPTMTAMR)

16/32-bit Timer 0 base: 0x4003.0000
 16/32-bit Timer 1 base: 0x4003.1000
 16/32-bit Timer 2 base: 0x4003.2000
 16/32-bit Timer 3 base: 0x4003.3000
 16/32-bit Timer 4 base: 0x4003.4000
 16/32-bit Timer 5 base: 0x4003.5000
 16/32-bit Timer 6 base: 0x400E.0000
 16/32-bit Timer 7 base: 0x400E.1000
 Offset 0x004

| | 0x7 | Clear CCP immediately and set on Time-Out | | |

| Bit/Field | Name | Type | Reset | Description |
|-----------|---------|------|-------|---|
| 12 | TACINTD | RW | 0 | <p>One-shot/Periodic Interrupt Disable</p> <p>Value Description</p> <p>0 Time-out interrupt functions as normal.</p> <p>1 Time-out interrupt are disabled.</p> <p>Note: Setting the TACINTD bit in the GPTMTAMR register does not have an effect on the μDMA or ADC interrupt time-out event trigger assertions. If the TATODMAEN bit is set in the GPTMDMAEV register or the TATOADCEN bit is set in the GPTMADCEV register, a μDMA or ADC time-out trigger is sent to the μDMA or ADC, respectively, even if the TACINTD bit is set.</p> |
| 11 | TAPLO | RW | 0 | <p>GPTM Timer A PWM Legacy Operation</p> <p>Value Description</p> <p>0 Legacy operation with CCP pin driven Low when the GPTMTAILR is reloaded after the timer reaches 0.</p> <p>1 CCP is driven High when the GPTMTAILR is reloaded after the timer reaches 0.</p> <p>This bit is only valid in PWM mode.</p> |
| 10 | TAMRSU | RW | 0 | <p>GPTM Timer A Match Register Update</p> <p>Value Description</p> <p>0 Update the GPTMTAMATCHR register and the GPTMTAPR register, if used, on the next cycle.</p> <p>1 Update the GPTMTAMATCHR register and the GPTMTAPR register, if used, on the next timeout.</p> <p>If the timer is disabled (TAEN is clear) when this bit is set, GPTMTAMATCHR and GPTMTAPR are updated when the timer is enabled. If the timer is stalled (TASTALL is set), GPTMTAMATCHR and GPTMTAPR are updated according to the configuration of this bit.</p> |
| 9 | TAPWMIE | RW | 0 | <p>GPTM Timer A PWM Interrupt Enable</p> <p>This bit enables interrupts in PWM mode on rising, falling, or both edges of the CCP output, as defined by the TAEVENT field in the GPTMCTL register.</p> <p>In addition, when this bit is set and a capture event occurs, Timer A automatically generates triggers to the ADC and DMA if the trigger capability is enabled by setting the TAOTE bit in the GPTMCTL register and the CAEDMAEN bit in the GPTMDMAEV register, respectively.</p> <p>Value Description</p> <p>0 Capture event interrupt is disabled.</p> <p>1 Capture event interrupt is enabled.</p> <p>This bit is only valid in PWM mode.</p> |

| Bit/Field | Name | Type | Reset | Description |
|-----------|---------|------|-------|--|
| 8 | TAILD | RW | 0 | <p>GPTM Timer A Interval Load Write</p> <p>Value Description</p> <p>0 Update the GPTMTAR and GPTMTAV registers with the value in the GPTMTAILR register on the next cycle. Also update the GPTMTAPS register with the value in the GPTMTAPR register on the next cycle.</p> <p>1 Update the GPTMTAR and GPTMTAV registers with the value in the GPTMTAILR register on the next timeout. Also update the GPTMTAPS register with the value in the GPTMTAPR register on the next timeout.</p> <p>Note the state of this bit has no effect when counting up.</p> <p>The bit descriptions above apply if the timer is enabled and running. If the timer is disabled (TAEN is clear) when this bit is set, GPTMTAR, GPTMTAV and GPTMTAPs, are updated when the timer is enabled. If the timer is stalled (TASTALL is set), GPTMTAR and GPTMTAPS are updated according to the configuration of this bit.</p> |
| 7 | TASNAPS | RW | 0 | <p>GPTM Timer A Snap-Shot Mode</p> <p>Value Description</p> <p>0 Snap-shot mode is disabled.</p> <p>1 If Timer A is configured in the periodic mode, the actual free-running, capture or snapshot value of Timer A is loaded at the time-out event/capture or snapshot event into the GPTM Timer A (GPTMTAR) register. If the timer prescaler is used, the prescaler snapshot is loaded into the GPTM Timer A (GPTMTAPR).</p> |
| 6 | TAWOT | RW | 0 | <p>GPTM Timer A Wait-on-Trigger</p> <p>Note: If the application requires cyclical daisy-chaining, the TAWOT bit in the GPTMTAMR register of Timer 0 can be set. In this case, Timer 0 waits for a trigger from the last timer module in the chain.</p> <p>Value Description</p> <p>0 Timer A begins counting as soon as it is enabled.</p> <p>1 If Timer A is enabled (TAEN is set in the GPTMCTL register), Timer A does not begin counting until it receives a trigger from the timer in the previous position in the daisy chain, see Figure 16-8 on page 1119. This function is valid for one-shot, periodic, and PWM modes.</p> |

| Bit/Field | Name | Type | Reset | Description |
|-----------|--------|------|-------|---|
| 5 | TAMIE | RW | 0 | <p>GPTM Timer A Match Interrupt Enable</p> <p>Value Description</p> <p>0 The match interrupt is disabled for match events.</p> <p>Note: Clearing the TAMIE bit in the GPTMTAMR register prevents assertion of μDMA or ADC requests generated on a match event. Even if the TATODMAEN bit is set in the GPTMDMAEV register or the TATOADCEN bit is set in the GPTMADCEV register, a μDMA or ADC match trigger is not sent to the μDMA or ADC, respectively, when the TAMIE bit is clear.</p> <p>1 An interrupt is generated when the match value in the GPTMTAMATCHR register is reached in the one-shot and periodic modes.</p> |
| 4 | TACDIR | RW | 0 | <p>GPTM Timer A Count Direction</p> <p>Value Description</p> <p>0 The timer counts down.</p> <p>1 The timer counts up. When counting up, the timer starts from a value of 0x0.</p> <p>When in PWM or RTC mode, the status of this bit is ignored. PWM mode always counts down and RTC mode always counts up.</p> |
| 3 | TAAMS | RW | 0 | <p>GPTM Timer A Alternate Mode Select</p> <p>The TAAMS values are defined as follows:</p> <p>Value Description</p> <p>0 Capture or compare mode is enabled.</p> <p>1 PWM mode is enabled.</p> <p>Note: To enable PWM mode, you must also clear the TACMR bit and configure the TAMR field to 0x1 or 0x2.</p> |

| 1:0 | TAMR | RW | 0x0 | GPTM Timer A Mode The TAMR values are defined as follows: Value Description 0x0 Reserved 0x1 One-Shot Timer mode 0x2 Periodic Timer mode 0x3 Capture mode The Timer mode is based on the timer configuration defined by bits 2:0 in the GPTMCFG register. |

Register 3: GPTM Timer B Mode (GPTMTBMR), offset 0x008

This register configures the GPTM based on the configuration selected in the **GPTMCFG** register. When in PWM mode, set the **TBAMS** bit, clear the **TBCMR** bit, and configure the **TBMR** field to 0x1 or 0x2.

This register controls the modes for Timer B when it is used individually. When Timer A and Timer B are concatenated, this register is ignored and **GPTMTAMR** controls the modes for both Timer A and Timer B.

Important: Except for the **TCACT** bit field, all other bits in this register should only be changed when the **TBEN** bit in the **GPTMCTL** register is cleared.

Register 4: GPTM Control (GPTMCTL), offset 0x00C

This register is used alongside the **GPTMCFG** and **GMTMTnMR** registers to fine-tune the timer configuration, and to enable other features such as timer stall and the output trigger. The output trigger can be used to initiate transfers on the ADC module.

Important: Bits in this register should only be changed when the **TnEN** bit for the respective timer is cleared.

Register 6: GPTM Interrupt Mask (GPTMIMR), offset 0x018

This register allows software to enable/disable GPTM controller-level interrupts. Setting a bit enables the corresponding interrupt, while clearing a bit disables it.

GPTM Interrupt Mask (GPTMIMR)

Register 7: GPTM Raw Interrupt Status (GPTMRIS), offset 0x01C

This register shows the state of the GPTM's internal interrupt signal. These bits are set whether or not the interrupt is masked in the **GPTMIMR** register. Each bit can be cleared by writing a 1 to its corresponding bit in **GPTMICR**.

Note: The state of the **GPTMRIS** register is not affected by disabling and then re-enabling the timer using the **TnEN** bits in the **GPTM Control (GPTMCTL)** register. If an application requires that all or certain status bits should not carry over after re-enabling the timer, then the appropriate bits in the **GPTMRIS** register should be cleared using the **GPTMICR** register prior to re-enabling the timer. If this is not done, any status bits set in the **GPTMRIS** register and unmasked in the **GPTMIMR** register generate an interrupt once the timer is re-enabled.

GPTM Raw Interrupt Status (GPTMRIS)

Register 8: GPTM Masked Interrupt Status (GPTMMIS), offset 0x020

This register show the state of the GPTM's controller-level interrupt. If an interrupt is unmasked in **GPTMIMR**, and there is an event that causes the interrupt to be asserted, the corresponding bit is set in this register. All bits are cleared by writing a 1 to the corresponding bit in **GPTMICR**.

Register 10: GPTM Timer A Interval Load (GPTMTAILR), offset 0x028

When the timer is counting down, this register is used to load the starting count value into the timer. When the timer is counting up, this register sets the upper bound for the timeout event.

When a GPTM is configured to one of the 32-bit modes, **GPTMTAILR** appears as a 32-bit register (the upper 16-bits correspond to the contents of the **GPTM Timer B Interval Load (GPTMTBILR)** register). In a 16-bit mode, the upper 16 bits of this register read as 0s and have no effect on the state of **GPTMTBILR**.

GPTM Timer A Interval Load (GPTMTAILR)

16/32-bit Timer 0 base: 0x4003.0000
 16/32-bit Timer 1 base: 0x4003.1000
 16/32-bit Timer 2 base: 0x4003.2000
 16/32-bit Timer 3 base: 0x4003.3000
 16/32-bit Timer 4 base: 0x4003.4000
 16/32-bit Timer 5 base: 0x4003.5000
 16/32-bit Timer 6 base: 0x400E.0000
 16/32-bit Timer 7 base: 0x400E.1000
 Offset 0x028
 Type RW, reset 0xFFFF.FFFF

| Bit/Field | Name | Type | Reset | Description |
|-----------|-------|------|-------------|---|
| 31:0 | TAILR | RW | 0xFFFF.FFFF | GPTM Timer A Interval Load Register Writing this field loads the counter for Timer A. A read returns the current value of GPTMTAILR . |

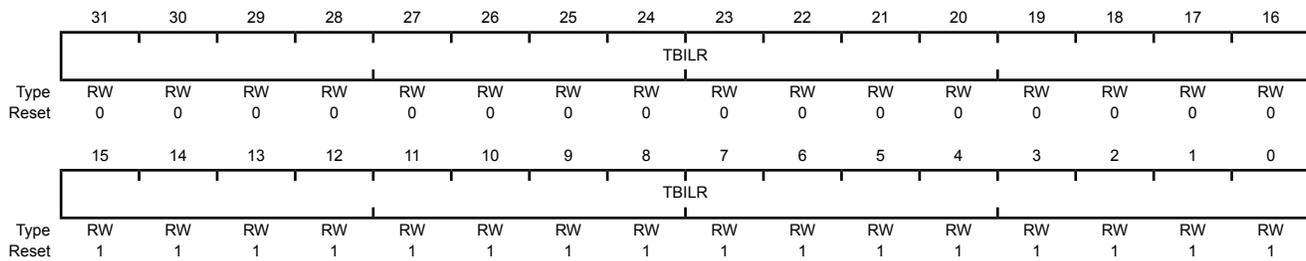

Register 11: GPTM Timer B Interval Load (GPTMTBILR), offset 0x02C

When the timer is counting down, this register is used to load the starting count value into the timer. When the timer is counting up, this register sets the upper bound for the timeout event.

When a GPTM is configured to one of the 32-bit modes, the contents of bits 15:0 in this register are loaded into the upper 16 bits of the **GPTMTAILR** register. Reads from this register return the current value of Timer B and writes are ignored. In a 16-bit mode, bits 15:0 are used for the load value. Bits 31:16 are reserved in both cases.

GPTM Timer B Interval Load (GPTMTBILR)

16/32-bit Timer 0 base: 0x4003.0000
 16/32-bit Timer 1 base: 0x4003.1000
 16/32-bit Timer 2 base: 0x4003.2000
 16/32-bit Timer 3 base: 0x4003.3000
 16/32-bit Timer 4 base: 0x4003.4000
 16/32-bit Timer 5 base: 0x4003.5000

Register 12: GPTM Timer A Match (GPTMTAMATCHR), offset 0x030

This register is loaded with a match value. Interrupts can be generated when the timer value is equal to the value in this register in one-shot or periodic mode.

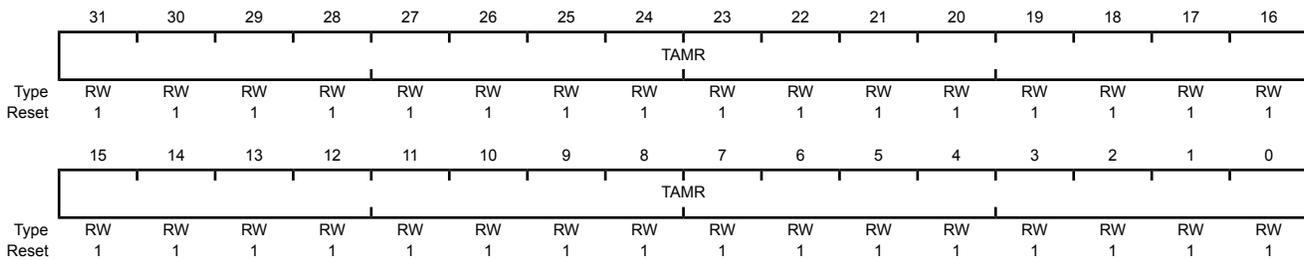

In Edge-Count mode, this register along with **GPTMTAILR**, determines how many edge events are counted. The total number of edge events counted is equal to the value in **GPTMTAILR** minus this value. Note that in edge-count mode, when executing an up-count, the value of **GPTMTnPR** and **GPTMTnILR** must be greater than the value of **GPTMTnPMR** and **GPTMTnMATCHR**.

In PWM mode, this value along with **GPTMTAILR**, determines the duty cycle of the output PWM signal.

When a 16/32-bit GPTM is configured to one of the 32-bit modes, **GPTMTAMATCHR** appears as a 32-bit register (the upper 16-bits correspond to the contents of the **GPTM Timer B Match (GPTMTBMATCHR)** register). In a 16-bit mode, the upper 16 bits of this register read as 0s and have no effect on the state of **GPTMTBMATCHR**.

GPTM Timer A Match (GPTMTAMATCHR)

16/32-bit Timer 0 base: 0x4003.0000
 16/32-bit Timer 1 base: 0x4003.1000
 16/32-bit Timer 2 base: 0x4003.2000
 16/32-bit Timer 3 base: 0x4003.3000
 16/32-bit Timer 4 base: 0x4003.4000
 16/32-bit Timer 5 base: 0x4003.5000
 16/32-bit Timer 6 base: 0x400E.0000

| 31:0 | TAMR | RW | 0xFFFF.FFFF | GPTM Timer A Match Register This value is compared to the GPTMTAR register to determine match events. |

Register 13: GPTM Timer B Match (GPTMTBMATCHR), offset 0x034

This register is loaded with a match value. Interrupts can be generated when the timer value is equal to the value in this register in one-shot or periodic mode.

In Edge-Count mode, this register along with **GPTMTBILR** determines how many edge events are counted. The total number of edge events counted is equal to the value in **GPTMTBILR** minus this value. Note that in edge-count mode, when executing an up-count, the value of **GPTMTnPR** and **GPTMTnILR** must be greater than the value of **GPTMTnPMR** and **GPTMTnMATCHR**.

In PWM mode, this value along with **GPTMTBILR**, determines the duty cycle of the output PWM signal.

When a GPTM is configured to one of the 32-bit modes, the contents of bits 15:0 in this register are loaded into the upper 16 bits of the **GPTMTAMATCHR** register. Reads from this register return the current match value of Timer B and writes are ignored. In a 16-bit mode, bits 15:0 are used for the match value. Bits 31:16 are reserved in both cases.

Register 14: GPTM Timer A Prescale (GPTMTAPR), offset 0x038

This register allows software to extend the range of the timers when they are used individually. When in one-shot or periodic down count modes, this register acts as a true prescaler for the timer counter. When acting as a true prescaler, the prescaler counts down to 0 before the value in the **GPTMTAR** and **GPTMTAV** registers are incremented. In all other individual/split modes, this register is a linear extension of the upper range of the timer counter, holding bits 23:16 in the 16-bit modes of the 16/32-bit GPTM.

GPTM Timer A Prescale (GPTMTAPR)

16/32-bit Timer 0 base: 0x4003.0000
 16/32-bit Timer 1 base: 0x4003.1000
 16/32-bit Timer 2 base: 0x4003.2000

Register 18: GPTM Timer A (GPTMTAR), offset 0x048

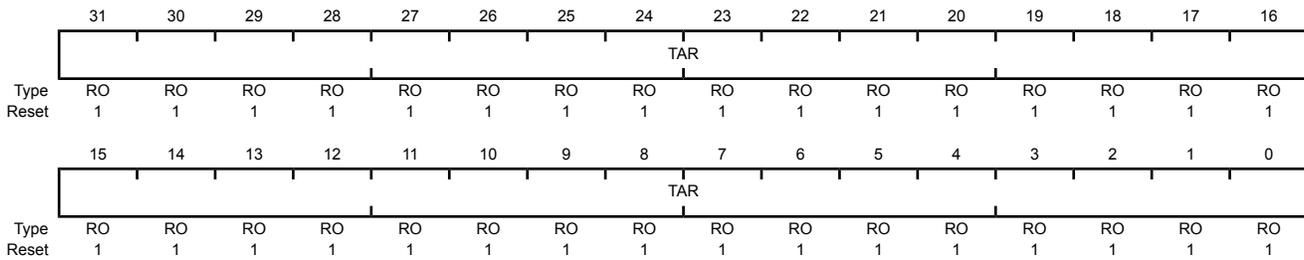

This register shows the current value of the Timer A counter in all cases except for Input Edge Count and Time modes. In the Input Edge Count mode, this register contains the number of edges that have occurred. In the Input Edge Time mode, this register contains the time at which the last edge event took place.

Note: When an alternate clock source is enabled, a read of this register returns the current count -1.

When a GPTM is configured to one of the 32-bit modes, **GPTMTAR** appears as a 32-bit register (the upper 16-bits correspond to the contents of the **GPTM Timer B (GPTMTBR)** register). In the 16-bit Input Edge Count, Input Edge Time, and PWM modes, bits 15:0 contain the value of the counter and bits 23:16 contain the value of the prescaler, which is the upper 8 bits of the count. Bits 31:24 always read as 0. To read the value of the prescaler in 16-bit One-Shot and Periodic modes, read bits [23:16] in the **GPTMTAV** register. To read the value of the prescaler in periodic snapshot mode, read the **Timer A Prescale Snapshot (GPTMTAPS)** register.

GPTM Timer A (GPTMTAR)

16/32-bit Timer 0 base: 0x4003.0000
 16/32-bit Timer 1 base: 0x4003.1000
 16/32-bit Timer 2 base: 0x4003.2000
 16/32-bit Timer 3 base: 0x4003.3000
 16/32-bit Timer 4 base: 0x4003.4000
 16/32-bit Timer 5 base: 0x4003.5000
 16/32-bit Timer 6 base: 0x400E.0000
 16/32-bit Timer 7 base: 0x400E.1000
 Offset 0x048
 Type RO, reset 0xFFFF.FFFF

| Bit/Field | Name | Type | Reset | Description |
|-----------|------|------|-------------|-----------------------|
| 31:0 | TAR | RO | 0xFFFF.FFFF | GPTM Timer A Register |

A read returns the current value of the **GPTM Timer A Count Register**, in all cases except for Input Edge Count and Time modes. In the Input Edge Count mode, this register contains the number of edges that have occurred. In the Input Edge Time mode, this register contains the time at which the last edge event took place.

Register 19: GPTM Timer B (GPTMTBR), offset 0x04C

This register shows the current value of the Timer B counter in all cases except for Input Edge Count and Time modes. In the Input Edge Count mode, this register contains the number of edges that have occurred. In the Input Edge Time mode, this register contains the time at which the last edge event took place.

Note: When an alternate clock source is enabled, a read of this register returns the current count -1.

When a GPTM is configured to one of the 32-bit modes, the contents of bits 15:0 in this register are loaded into the upper 16 bits of the **GPTMTAR** register. Reads from this register return the current value of Timer B. In a 16-bit mode, bits 15:0 contain the value of the counter and bits 23:16 contain the value of the prescaler in Input Edge Count, Input Edge Time, and PWM modes, which is the upper 8 bits of the count. Bits 31:24 always read as 0. To read the value of the prescaler in 16-bit One-Shot and Periodic modes, read bits [23:16] in the **GPTMTBV** register. To read the value of the prescaler in periodic snapshot mode, read the **Timer B Prescale Snapshot (GPTMTBPS)** register.

| Bit/Field | Name | Type | Reset | Description |
|-----------|------|------|-------------|-----------------------|
| 31:0 | TBR | RO | 0x0000.FFFF | GPTM Timer B Register |

A read returns the current value of the **GPTM Timer B Count Register**, in all cases except for Input Edge Count and Time modes. In the Input Edge Count mode, this register contains the number of edges that have occurred. In the Input Edge Time mode, this register contains the time at which the last edge event took place.

Register 20: GPTM Timer A Value (GPTMTAV), offset 0x050

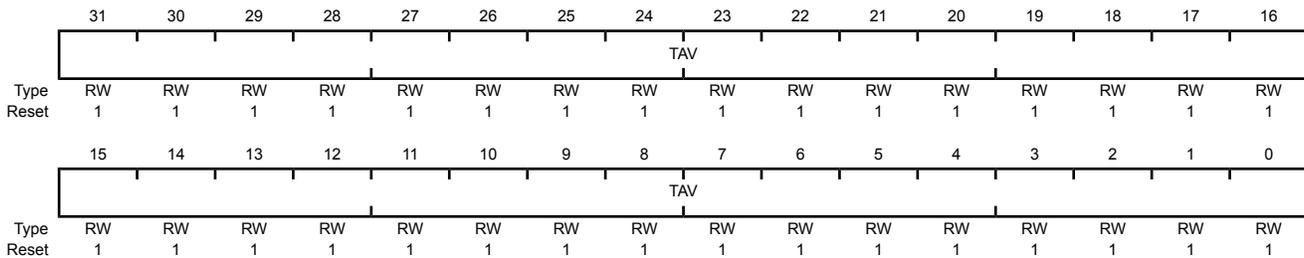

When read, this register shows the current, free-running value of Timer A in all modes. Software can use this value to determine the time elapsed between an interrupt and the ISR entry when using the snapshot feature with the periodic operating mode. When written, the value written into this register is loaded into the **GPTMTAR** register on the next clock cycle.

Note: When an alternate clock source is enabled, a read of this register returns the current count -1.

When a 16/32-bit GPTM is configured to one of the 32-bit modes, **GPTMTAV** appears as a 32-bit register (the upper 16-bits correspond to the contents of the **GPTM Timer B Value (GPTMTBV)** register). In a 16-bit mode, bits 15:0 contain the value of the counter and bits 23:16 contain the current, free-running value of the prescaler, which is the upper 8 bits of the count in Input Edge Count, Input Edge Time, PWM and one-shot or periodic up count modes. In one-shot or periodic down count modes, the prescaler stored in 23:16 is a true prescaler, meaning bits 23:16 count down before decrementing the value in bits 15:0. The prescaler in bits 31:24 always reads as 0.

GPTM Timer A Value (GPTMTAV)

16/32-bit Timer 0 base: 0x4003.0000
 16/32-bit Timer 1 base: 0x4003.1000
 16/32-bit Timer 2 base: 0x4003.2000
 16/32-bit Timer 3 base: 0x4003.3000
 16/32-bit Timer 4 base: 0x4003.4000
 16/32-bit Timer 5 base: 0x4003.5000
 16/32-bit Timer 6 base: 0x400E.0000
 16/32-bit Timer 7 base: 0x400E.1000
 Offset 0x050
 Type RW, reset 0xFFFF.FFFF

| Bit/Field | Name | Type | Reset | Description |
|-----------|------|------|-------------|--------------------|
| 31:0 | TAV | RW | 0xFFFF.FFFF | GPTM Timer A Value |

A read returns the current, free-running value of Timer A in all modes. When written, the value written into this register is loaded into the **GPTMTAR** register on the next clock cycle.

Note: In 16-bit mode, only the lower 16-bits of the **GPTMTAV** register can be written with a new value. Writes to the prescaler bits have no effect.

Register 21: GPTM Timer B Value (GPTMTBV), offset 0x054

When read, this register shows the current, free-running value of Timer B in all modes. Software can use this value to determine the time elapsed between an interrupt and the ISR entry. When written, the value written into this register is loaded into the **GPTMTBR** register on the next clock cycle.

Note: When an alternate clock source is enabled, a read of this register returns the current count -1.

When a 16/32-bit GPTM is configured to one of the 32-bit modes, the contents of bits 15:0 in this register are loaded into the upper 16 bits of the **GPTMTAV** register. Reads from this register return the current free-running value of Timer B. In a 16-bit mode, bits 15:0 contain the value of the counter and bits 23:16 contain the current, free-running value of the prescaler, which is the upper 8 bits of the count in Input Edge Count, Input Edge Time, PWM and one-shot or periodic up count modes. In one-shot or periodic down count modes, the prescaler stored in 23:16 is a true prescaler, meaning bits 23:16 count down before decrementing the value in bits 15:0. The prescaler in bits 31:24 always reads as 0.

GPTM Timer B Value (GPTMTBV)

16/32-bit Timer 0 base: 0x4003.0000
 16/32-bit Timer 1 base: 0x4003.1000

| Bit/Field | Name | Type | Reset | Description |
|-----------|------|------|-------------|--------------------|
| 31:0 | TBV | RW | 0x0000.FFFF | GPTM Timer B Value |

A read returns the current, free-running value of Timer A in all modes. When written, the value written into this register is loaded into the **GPTMTAR** register on the next clock cycle.

Note: In 16-bit mode, only the lower 16-bits of the **GPTMTBV** register can be written with a new value. Writes to the prescaler bits have no effect.

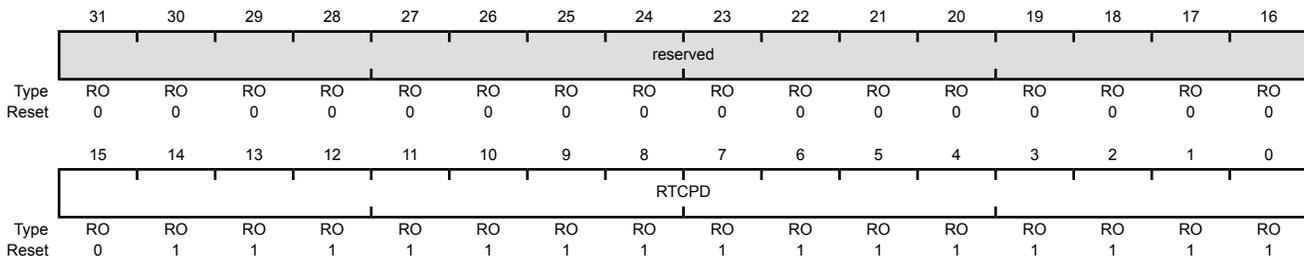

Register 22: GPTM RTC Predivide (GPTMRTCPD), offset 0x058

This register provides the current RTC predivider value when the timer is operating in RTC mode. Software must perform an atomic access with consecutive reads of the **GPTMTAR**, **GPTMTBR**, and **GPTMRTCPD** registers.

Note: When an alternate clock source is enabled, a read of this register returns the current count -1.

GPTM RTC Predivide (GPTMRTCPD)

16/32-bit Timer 0 base: 0x4003.0000

| 5 | SYNCCNT | RO | 0x1 | Synchronize Start Value Description 0 Timer is not capable of synchronizing the counter value with other GPTimers. 1 Timer is capable of synchronizing the counter value with other Timers. |
| 4 | CHAIN | RO | 0x1 | Chain with Other Timers Value Description 0 Timer is not capable of chaining with the previously numbered Timer. 1 Timer is capable of chaining with the previously numbered Timer. |

Note that although this bit is set for Timer 0A, this timer cannot chain because there is not a previously numbered Timer.

| Bit/Field | Name | Type | Reset | Description |
|-----------|------|------|-------|---|
| 3:0 | SIZE | RO | 0x0 | Count Size |
| | | | | Value Description |
| | | | | 0 Timer A and Timer B counters are 16 bits each with an 8-bit prescale counter. |
| | | | | 1 Timer A and Timer B counters are 32 bits each with a 16-bit prescale counter. |

Register 28: GPTM Clock Configuration (GPTMCC), offset 0xFC8

The **GPTMCC** register controls the clock source for the General-Purpose Timer module.

Note: When the **ALTCLK** bit is set in the **GPTMCC** register to enable using the alternate clock source, the synchronization imposes restrictions on the starting count value (down-count), terminal value (up-count) and the match value. This restriction applies to all modes of operation. Each event must be spaced by 4 Timer (ALTCLK) clock periods + 2 system clock periods. If some events do not meet this requirement, then it is possible that the timer block may need to be reset for correct functionality to be restored.

Example: $ALTCLK = T_{PIOSC} = 62.5\text{ns}$ (16Mhz Trimmed)

$T_{hclk} = 1\mu\text{s}$ (1Mhz)

$4 * 62.5\text{ns} + 2 * 1\mu\text{s} = 2.25\mu\text{s}$ $2.25\mu\text{s} / 62.5\text{ns} = 36$ or 0x23

The minimum values for the periodic or one-shot with a match interrupt enabled are:
GPTMTAMATCHR = 0x23 **GPTMTAILR = 0x46**

GPTM Clock Configuration (GPTMCC)

16/32-bit Timer 0 base: 0x4003.0000

| | | | 1 | Alternate clock source as defined by ALTCLKCFG register in System Control Module. |

17 Watchdog Timers

A watchdog timer can generate a non-maskable interrupt (NMI), a regular interrupt or a reset when a time-out value is reached. The watchdog timer is used to regain control when a system has failed due to a software error or due to the failure of an external device to respond in the expected way. The TM4C129XKCZAD microcontroller has two Watchdog Timer Modules, one module is clocked by the system clock (Watchdog Timer 0) and the other (Watchdog Timer 1) is clocked by the clock source programmed in the `ALTCLK` field of the **Alternate Clock Configuration (ALTCLKCFG)** register, System Control offset 0x138. The two modules are identical except that WDT1 is in a different clock domain, and therefore requires synchronizers. As a result, WDT1 has a bit defined in the **Watchdog Timer Control (WDTCTL)** register to indicate when a write to a WDT1 register is complete. Software can use this bit to ensure that the previous access has completed before starting the next access.

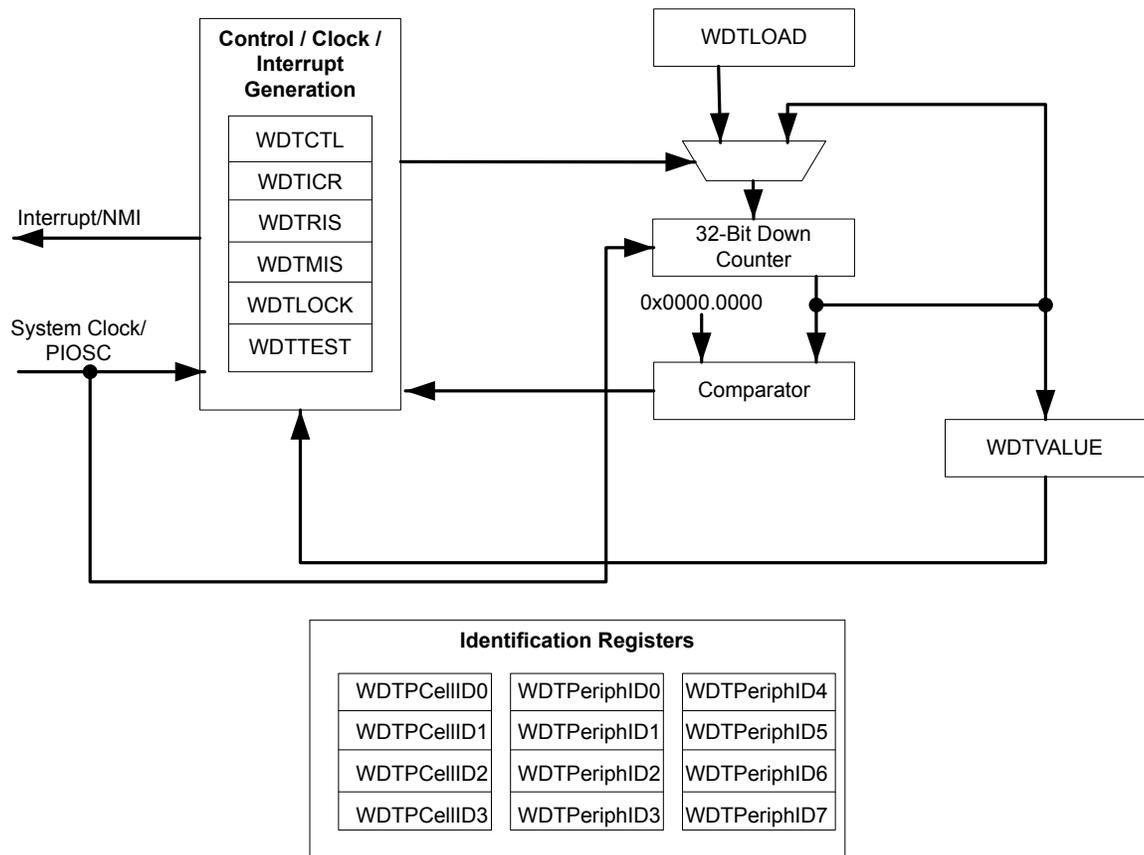

The TM4C129XKCZAD controller has two Watchdog Timer modules with the following features:

- 32-bit down counter with a programmable load register
- Separate watchdog clock with an enable
- Programmable interrupt generation logic with interrupt masking and optional NMI function
- Lock register protection from runaway software
- Reset generation logic with an enable/disable
- User-enabled stalling when the microcontroller asserts the CPU Halt flag during debug

The Watchdog Timer can be configured to generate an interrupt to the controller on its first time-out, and to generate a reset signal on its second time-out. Once the Watchdog Timer has been configured, the lock register can be written to prevent the timer configuration from being inadvertently altered.

17.1 Block Diagram

Figure 17-1. WDT Module Block Diagram

17.2 Functional Description

The Watchdog Timer module generates the first time-out signal when the 32-bit counter reaches the zero state after being enabled; enabling the counter also enables the watchdog timer interrupt. The watchdog interrupt can be programmed to be a non-maskable interrupt (NMI) using the `INTTYPE` bit in the **WDTCTL** register. After the first time-out event, the 32-bit counter is re-loaded with the value of the **Watchdog Timer Load (WDTLOAD)** register, and the timer resumes counting down from that value. Once the Watchdog Timer has been configured, the **Watchdog Timer Lock (WDTLOCK)** register is written, which prevents the timer configuration from being inadvertently altered by software.

If the timer counts down to its zero state again before the first time-out interrupt is cleared, and the reset signal has been enabled by setting the `RESEN` bit in the **WDTCTL** register, the Watchdog timer asserts its reset signal to the system. If the interrupt is cleared before the 32-bit counter reaches its second time-out, the 32-bit counter is loaded with the value in the **WDTLOAD** register, and counting resumes from that value.

If **WDTLOAD** is written with a new value while the Watchdog Timer counter is counting, then the counter is loaded with the new value and continues counting.

Writing to **WDTLOAD** does not clear an active interrupt. An interrupt must be specifically cleared by writing to the **Watchdog Interrupt Clear (WDTICR)** register.

The Watchdog module interrupt and reset generation can be enabled or disabled as required. When the interrupt is re-enabled, the 32-bit counter is preloaded with the load register value and not its last state.

The watchdog timer is disabled by default out of reset. To achieve maximum watchdog protection of the device, the watchdog timer can be enabled at the start of the reset vector.

17.2.1 Register Access Timing

Because the Watchdog Timer 1 module has an independent clocking domain, its registers must be written with a timing gap between accesses. Software must guarantee that this delay is inserted between back-to-back writes to WDT1 registers or between a write followed by a read to the registers. The timing for back-to-back reads from the WDT1 module has no restrictions. The **WRC** bit in the **Watchdog Control (WDTCTL)** register for WDT1 indicates that the required timing gap has elapsed. This bit is cleared on a write operation and set once the write completes, indicating to software that another write or read may be started safely. Software should poll **WDTCTL** for **WRC=1** prior to accessing another register. Note that WDT0 does not have this restriction as it runs off the system clock.

17.3 Initialization and Configuration

To use the WDT, its peripheral clock must be enabled by setting the **Rn** bit in the **Watchdog Timer Run Mode Clock Gating Control (RCGCWD)** register, see page 396.

The Watchdog Timer is configured using the following sequence:

1. Load the **WDTLOAD** register with the desired timer load value.
2. If WDT1, wait for the **WRC** bit in the **WDTCTL** register to be set.
3. Set the **INTEN** bit (if interrupts are required) or the **RESEN** bit (if a reset is required after two timeouts) in the **WDTCTL** register. The Watchdog Timer starts when either of them is enabled.

If software requires that all of the watchdog registers are locked, the Watchdog Timer module can be fully locked by writing any value to the **WDTLOCK** register. To unlock the Watchdog Timer, write a value of 0x1ACC.E551.

To service the watchdog, periodically reload the count value into the **WDTLOAD** register to restart the count. The interrupt can be enabled using the **INTEN** bit in the **WDTCTL** register to allow the processor to attempt corrective action if the watchdog is not serviced often enough. The **RESEN** bit in **WDTCTL** can be set so that the system resets if the failure is not recoverable using the ISR.

Note: The application should be sure not to modify the **ALTCLK** encoding in the **ALTCLKCFG** register while the WDT1 is enabled and running.

17.4 Register Map

Table 17-1 on page 1181 lists the Watchdog registers. The offset listed is a hexadecimal increment to the register's address, relative to the Watchdog Timer base address:

- WDT0: 0x4000.0000
- WDT1: 0x4000.1000

Note that the Watchdog Timer module clock must be enabled before the registers can be programmed (see page 396).

Table 17-1. Watchdog Timers Register Map

| Offset | Name | Type | Reset | Description | See page |
|--------|-----------------|------|--|--------------------------------------|----------|
| 0x000 | WDTLOAD | RW | 0xFFFF.FFFF | Watchdog Load | 1182 |

17.5 Register Descriptions

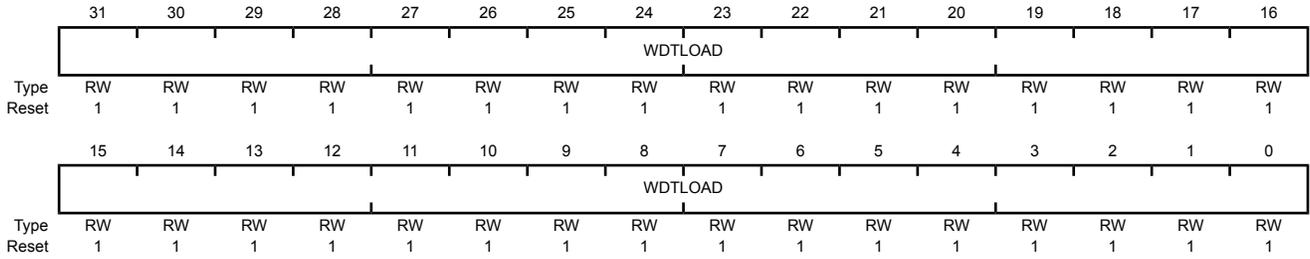

The remainder of this section lists and describes the WDT registers, in numerical order by address offset.

Register 1: Watchdog Load (WDTLOAD), offset 0x000

This register is the 32-bit interval value used by the 32-bit counter. When this register is written, the value is immediately loaded and the counter restarts counting down from the new value. If the **WDTLOAD** register is loaded with 0x0000.0000, an interrupt is immediately generated.

Watchdog Load (WDTLOAD)

WDT0 base: 0x4000.0000
 WDT1 base: 0x4000.1000
 Offset 0x000
 Type RW, reset 0xFFFF.FFFF

| Bit/Field | Name | Type | Reset | Description |
|-----------|---------|------|-------------|---------------------|
| 31:0 | WDTLOAD | RW | 0xFFFF.FFFF | Watchdog Load Value |

Register 2: Watchdog Value (WDTVALUE), offset 0x004

This register contains the current count value of the timer.

Watchdog Value (WDTVALUE)

WDT0 base: 0x4000.0000

WDT1 base: 0x4000.1000

Offset 0x004

Type RO, reset 0xFFFF.FFFF

| | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|-------|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| | WDTVALUE | | | | | | | | | | | | | | | |

| Reset | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|-------------|---|
| 31:0 | WDTVALUE | RO | 0xFFFF.FFFF | Watchdog Value Current value of the 32-bit down counter. |

Register 3: Watchdog Control (WDTCTL), offset 0x008

This register is the watchdog control register. The watchdog timer can be configured to generate a reset signal (on second time-out) or an interrupt on time-out.

When the watchdog interrupt has been enabled by setting the `INTEN` bit, all subsequent writes to the `INTEN` bit are ignored. The only mechanisms that can re-enable writes to this bit are a hardware reset or a software reset initiated by setting the appropriate bit in the **Watchdog Timer Software Reset (SRWD)** register.

Important: Because the Watchdog Timer 1 module has an independent clocking domain, its registers must be written with a timing gap between accesses. Software must guarantee that this delay is inserted between back-to-back writes to WDT1 registers or between a write followed by a read to the registers. The timing for back-to-back reads from the WDT1 module has no restrictions. The `WRC` bit in the **Watchdog Control (WDTCTL)** register for WDT1 indicates that the required timing gap has elapsed. This bit is cleared on a write operation and set once the write completes, indicating to software that another write or read may be started safely. Software should poll **WDTCTL** for `WRC=1` prior to accessing another register. Note that WDT0 does not have this restriction as it runs off the system clock and therefore does not have a `WRC` bit.

Watchdog Control (WDTCTL)

WDT0 base: 0x4000.0000

WDT1 base: 0x4000.1000

Offset 0x008

Type RW, reset 0x0000.0000 (WDT0) and 0x8000.0000 (WDT1)

| Value | Description | | | | | | | | | |
| 0 | Interrupt event disabled. Once this bit is set, it can only be cleared by a hardware reset or a software reset initiated by setting the appropriate bit in the Watchdog Timer Software Reset (SRWD) register. | | | | | | | | | |
| 1 | Interrupt event enabled. Once enabled, all writes are ignored. Setting this bit enables the Watchdog Timer. | | | | | | | | | |

Register 4: Watchdog Interrupt Clear (WDTICR), offset 0x00C

This register is the interrupt clear register. A write of any value to this register clears the Watchdog interrupt and reloads the 32-bit counter from the **WDTLOAD** register. Write to this register when a watchdog time-out interrupt has occurred to properly service the Watchdog. Value for a read or reset is indeterminate.

Note: Locking the watchdog registers by using the **WDTLOCK** register does not affect the **WDTICR** register and allows interrupts to always be serviced. Thus, a write at any time of the **WDTICR** register clears the **WDTMIS** register and reloads the 32-bit counter from the **WDTLOAD** register. The **WDTICR** register should only be written when interrupts have triggered and need to be serviced.

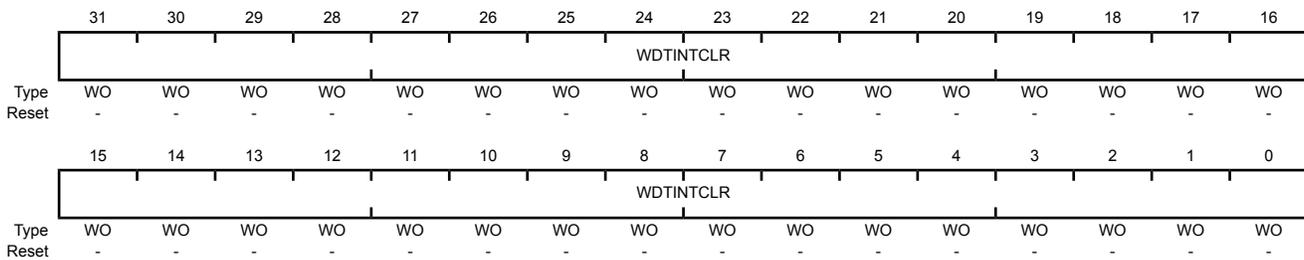

Watchdog Interrupt Clear (WDTICR)

WDT0 base: 0x4000.0000

WDT1 base: 0x4000.1000

Offset 0x00C

Type WO, reset -

| Bit/Field | Name | Type | Reset | Description |
|-----------|-----------|------|-------|--|

|-----------|----------|------|-----------|---|
| 31:9 | reserved | RO | 0x0000.00 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 8 | STALL | RW | 0 | Watchdog Stall Enable Value Description 0 The watchdog timer continues counting if the microcontroller is stopped with a debugger. 1 If the microcontroller is stopped with a debugger, the watchdog timer stops counting. Once the microcontroller is restarted, the watchdog timer resumes counting. |
| 7:0 | reserved | RO | 0x00 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |

Register 8: Watchdog Lock (WDTLOCK), offset 0xC00

Writing 0x1ACC.E551 to the **WDTLOCK** register enables write access to all other registers. Writing any other value to the **WDTLOCK** register re-enables the locked state for register writes to all the other registers, except for the **Watchdog Test (WDTTEST)** register. Reading the **WDTLOCK** register returns the lock status rather than the 32-bit value written. Therefore, when write accesses are disabled, reading the **WDTLOCK** register returns 0x0000.0001 (when locked; otherwise, the returned value is 0x0000.0000 (unlocked)).

Watchdog Lock (WDTLOCK)

WDT0 base: 0x4000.0000
 WDT1 base: 0x4000.1000
 Offset 0xC00
 Type RW, reset 0x0000.0000

| Bit/Field | Name | Type | Reset | Description |
|-----------|------|------|-------|-------------|
|-----------|------|------|-------|-------------|

| | | | | |
|------|---------|----|-------------|---------------|
| 31:0 | WDTLOCK | RW | 0x0000.0000 | Watchdog Lock |
|------|---------|----|-------------|---------------|

A write of the value 0x1ACC.E551 unlocks the watchdog registers for write access. A write of any other value reapplies the lock, preventing any register updates, except for the **WDTTEST** register. Avoid writes to the **WDTTEST** register when the watchdog registers are locked.

A read of this register returns the following values:

| Value | Description |
|-------------|-------------|
| 0x0000.0001 | Locked |
| 0x0000.0000 | Unlocked |

Register 9: Watchdog Peripheral Identification 4 (WDTPeriphID4), offset 0xFD0

The **WDTPeriphIDn** registers are hard-coded and the fields within the register determine the reset value.

18 Analog-to-Digital Converter (ADC)

An analog-to-digital converter (ADC) is a peripheral that converts a continuous analog voltage to a discrete digital number. Two identical converter modules are included, which share 24 input channels.

The TM4C129XKCZAD ADC module features 12-bit conversion resolution and supports 24 input channels, plus an internal temperature sensor. Each ADC module contains four programmable sequencers allowing the sampling of multiple analog input sources without controller intervention. Each sample sequencer provides flexible programming with fully configurable input source, trigger events, interrupt generation, and sequencer priority. In addition, the conversion value can optionally be diverted to a digital comparator module. Each ADC module provides eight digital comparators. Each digital comparator evaluates the ADC conversion value against its two user-defined values to determine the operational range of the signal. The trigger source for ADC0 and ADC1 may be independent or the two ADC modules may operate from the same trigger source and operate on the same or different inputs. A phase shifter can delay the start of sampling by a specified phase angle. When using both ADC modules, it is possible to configure the converters to start the conversions coincidentally or within a relative phase from each other, see “Sample Phase Control” on page 1210.

The TM4C129XKCZAD microcontroller provides two ADC modules with each having the following features:

- 24 shared analog input channels
- 12-bit precision ADC
- Single-ended and differential-input configurations
- On-chip internal temperature sensor
- Maximum sample rate of two million samples/second
- Optional, programmable phase delay
- Sample and hold window programmability
- Four programmable sample conversion sequencers from one to eight entries long, with corresponding conversion result FIFOs
- Flexible trigger control
 - Controller (software)
 - Timers
 - Analog Comparators
 - PWM
 - GPIO
- Hardware averaging of up to 64 samples
- Eight digital comparators

- Converter uses two external reference signals (VREF_{A+} and VREF_{A-}) or VDDA and GNDA as the voltage reference
- Power and ground for the analog circuitry is separate from the digital power and ground
- Efficient transfers using Micro Direct Memory Access Controller (μDMA)
 - Dedicated channel for each sample sequencer
 - ADC module uses burst requests for DMA
- Global Alternate Clock (ALTCLK) resource or System Clock (SYSCLK) can be used to generate ADC clock

18.1 Block Diagram

The TM4C129XKCZAD microcontroller contains two identical Analog-to-Digital Converter modules. These two modules, ADC0 and ADC1, share the same 24 analog input channels. Each ADC module operates independently and can therefore execute different sample sequences, sample any of the analog input channels at any time, and generate different interrupts and triggers. Figure 18-1 on page 1204 shows how the two modules are connected to analog inputs and the system bus.

Figure 18-1. Implementation of Two ADC Blocks

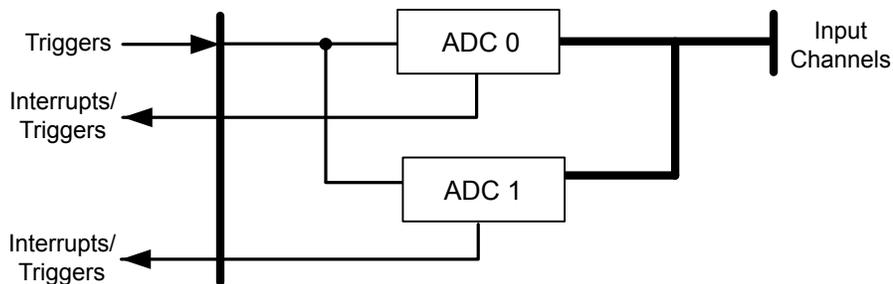

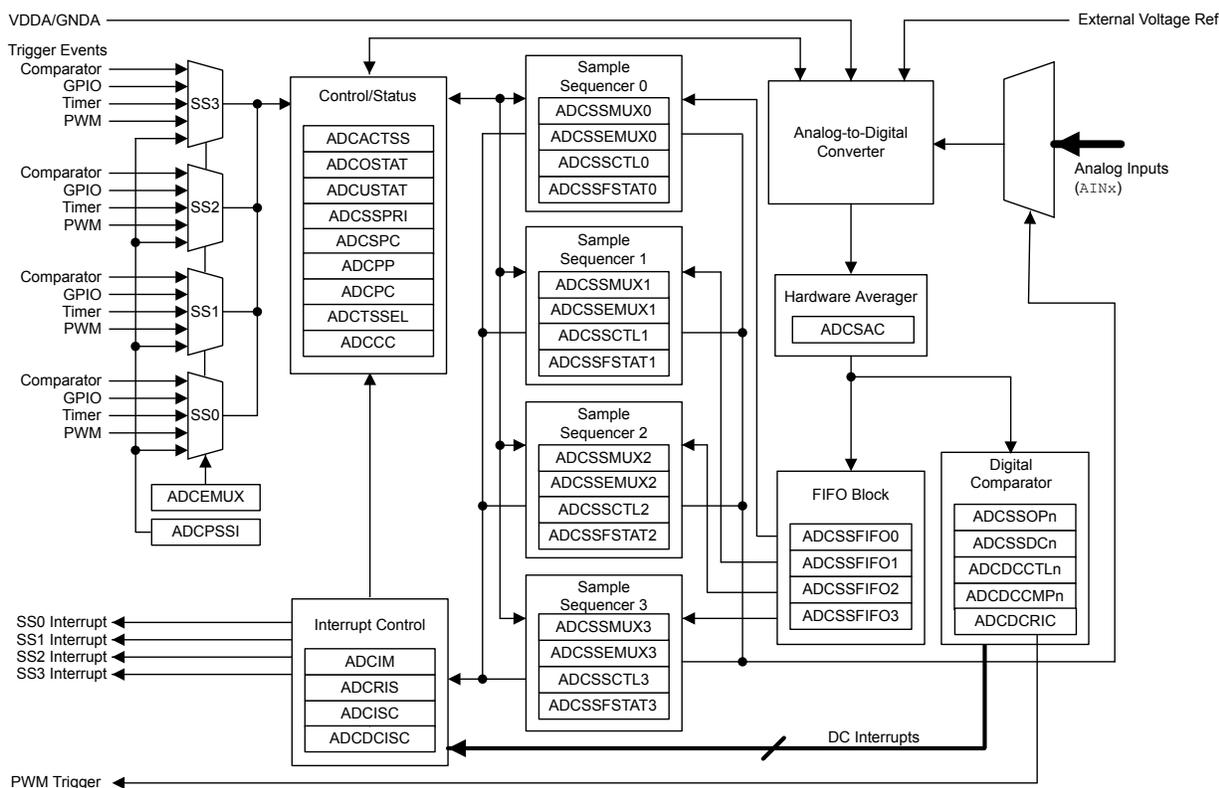

Figure 18-2 on page 1205 provides details on the internal configuration of the ADC controls and data registers.

Figure 18-2. ADC Module Block Diagram

18.2 Signal Description

The following table lists the external signals of the ADC module and describes the function of each. The AIN_x signals are analog functions for some GPIO signals. The column in the table below titled "Pin Mux/Pin Assignment" lists the GPIO pin placement for the ADC signals. These signals are configured by clearing the corresponding DEN bit in the **GPIO Digital Enable (GPIODEN)** register and setting the corresponding $AMSEL$ bit in the **GPIO Analog Mode Select (GPIOAMSEL)** register. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 772. The $VREFA+$ and $VREFA-$ signals (with the word "fixed" in the Pin Mux/Pin Assignment column) have a fixed pin assignment and function.

Table 18-1. ADC Signals (212BGA)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description |
|----------|------------|--------------------------|----------|-------------|--------------------------------------|
| AIN0 | G2 | PE3 | I | Analog | Analog-to-digital converter input 0. |
| AIN1 | G1 | PE2 | I | Analog | Analog-to-digital converter input 1. |
| AIN2 | H2 | PE1 | I | Analog | Analog-to-digital converter input 2. |
| AIN3 | H3 | PE0 | I | Analog | Analog-to-digital converter input 3. |
| AIN4 | B2 | PD7 | I | Analog | Analog-to-digital converter input 4. |
| AIN5 | B3 | PD6 | I | Analog | Analog-to-digital converter input 5. |
| AIN6 | B4 | PD5 | I | Analog | Analog-to-digital converter input 6. |
| AIN7 | A4 | PD4 | I | Analog | Analog-to-digital converter input 7. |

Table 18-1. ADC Signals (212BGA) (continued)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description |
|----------|------------|--------------------------|----------|-------------|--|
| AIN8 | B5 | PE5 | I | Analog | Analog-to-digital converter input 8. |
| AIN9 | A5 | PE4 | I | Analog | Analog-to-digital converter input 9. |
| AIN10 | C6 | PB4 | I | Analog | Analog-to-digital converter input 10. |
| AIN11 | B6 | PB5 | I | Analog | Analog-to-digital converter input 11. |
| AIN12 | D1 | PD3 | I | Analog | Analog-to-digital converter input 12. |
| AIN13 | D2 | PD2 | I | Analog | Analog-to-digital converter input 13. |
| AIN14 | C1 | PD1 | I | Analog | Analog-to-digital converter input 14. |
| AIN15 | C2 | PD0 | I | Analog | Analog-to-digital converter input 15. |
| AIN16 | J1 | PK0 | I | Analog | Analog-to-digital converter input 16. |
| AIN17 | J2 | PK1 | I | Analog | Analog-to-digital converter input 17. |
| AIN18 | K1 | PK2 | I | Analog | Analog-to-digital converter input 18. |
| AIN19 | K2 | PK3 | I | Analog | Analog-to-digital converter input 19. |
| AIN20 | A7 | PE6 | I | Analog | Analog-to-digital converter input 20. |
| AIN21 | B7 | PE7 | I | Analog | Analog-to-digital converter input 21. |
| AIN22 | A8 | PP7 | I | Analog | Analog-to-digital converter input 22. |
| AIN23 | B8 | PP6 | I | Analog | Analog-to-digital converter input 23. |
| VREFA+ | F4 | fixed | - | Analog | A reference voltage used to specify the voltage at which the ADC converts to a maximum value. This pin is used in conjunction with VREFA-, which specifies the minimum value. The voltage that is applied to VREFA+ is the voltage with which an AIN _n signal is converted to 4095. The VREFA+ voltage is limited to the range specified in Table 32-44 on page 2138. |
| VREFA- | G5 | fixed | - | Analog | A reference voltage used to specify the input voltage at which the ADC converts to a minimum value. This pin is used in conjunction with VREFA+, which specifies the maximum value. In other words, the voltage that is applied to VREFA- is the voltage with which an AIN _n signal is converted to 0, while the voltage that is applied to VREFA+ is the voltage with which an AIN _n signal is converted to 4095. The VREFA- voltage is limited to the range specified in Table 32-44 on page 2138. |

18.3 Functional Description

The TM4C129XKCZAD ADC collects sample data by using a programmable sequence-based approach instead of the traditional single or double-sampling approaches found on many ADC modules. Each *sample sequence* is a fully programmed series of consecutive (back-to-back) samples, allowing the ADC to collect data from multiple input sources without having to be re-configured or serviced by the processor. The programming of each sample in the sample sequence includes parameters such as the input source and mode (differential versus single-ended input), interrupt generation on sample completion, and the indicator for the last sample in the sequence. In addition, the μ DMA can be used to more efficiently move data from the sample sequencers without CPU intervention.

18.3.1 Sample Sequencers

The sampling control and data capture is handled by the sample sequencers. All of the sequencers are identical in implementation except for the number of samples that can be captured and the depth of the FIFO. Table 18-2 on page 1207 shows the maximum number of samples that each sequencer can capture and its corresponding FIFO depth. Each sample that is captured is stored in the FIFO. In this implementation, each FIFO entry is a 32-bit word, with the lower 12 bits containing the conversion result.

Table 18-2. Samples and FIFO Depth of Sequencers

| Sequencer | Number of Samples | Depth of FIFO |
|-----------|-------------------|---------------|
| SS3 | 1 | 1 |
| SS2 | 4 | 4 |
| SS1 | 4 | 4 |
| SS0 | 8 | 8 |

For a given sample sequence, each sample is defined by bit fields in the **ADC Sample Sequence Input Multiplexer Select (ADCSSMUXn)**, **ADC Sample Sequence Extended Input Multiplexer Select (ADCSEMUXn)** and **ADC Sample Sequence Control (ADCSSCTLn)** registers, where "n" corresponds to the sequence number. The **ADCSSMUXn** and **ADCSEMUXn** fields select the input pin, while the **ADCSSCTLn** fields contain the sample control bits corresponding to parameters such as temperature sensor selection, interrupt enable, end of sequence, and differential input mode. Sample sequencers are enabled by setting the respective **ASENn** bit in the **ADC Active Sample Sequencer (ADCACTSS)** register and should be configured before being enabled. Sampling is then initiated by setting the **SSn** bit in the **ADC Processor Sample Sequence Initiate (ADCPSSI)** register. In addition, sample sequences may be initiated on multiple ADC modules simultaneously using the **GSYNC** and **SYNCWAIT** bits in the **ADCPSSI** register during the configuration of each ADC module. For more information on using these bits, refer to page 1254.

When configuring a sample sequence, multiple uses of the same input pin within the same sequence are allowed. In the **ADCSSCTLn** register, the **IE_n** bits can be set for any combination of samples, allowing interrupts to be generated after every sample in the sequence if necessary. Also, the **END** bit can be set at any point within a sample sequence. For example, if Sequencer 0 is used, the **END** bit can be set in the nibble associated with the fifth sample, allowing Sequencer 0 to complete execution of the sample sequence after the fifth sample.

After a sample sequence completes execution, the result data can be retrieved from the **ADC Sample Sequence Result FIFO (ADCSSFIFO_n)** registers. The FIFOs are simple circular buffers that read a single address to "pop" result data. For software debug purposes, the positions of the FIFO head and tail pointers are visible in the **ADC Sample Sequence FIFO Status (ADCSSFSTAT_n)** registers along with **FULL** and **EMPTY** status flags. If a write is attempted when the FIFO is full, the write does not occur and an overflow condition is indicated. Overflow and underflow conditions are monitored using the **ADCOSTAT** and **ADCUSTAT** registers.

18.3.2 Module Control

Outside of the sample sequencers, the remainder of the control logic is responsible for tasks such as:

- Interrupt generation
- DMA operation

- Sequence prioritization
- Trigger configuration
- Comparator configuration
- External voltage reference
- Sample phase control
- Module clocking

18.3.2.1 Interrupts

The register configurations of the sample sequencers and digital comparators dictate which events generate raw interrupts, but do not have control over whether the interrupt is actually sent to the interrupt controller. The ADC module's interrupt signals are controlled by the state of the `MASK` bits in the **ADC Interrupt Mask (ADCIM)** register. Interrupt status can be viewed at two locations: the **ADC Raw Interrupt Status (ADCRIS)** register, which shows the raw status of the various interrupt signals; and the **ADC Interrupt Status and Clear (ADCISC)** register, which shows active interrupts that are enabled by the **ADCIM** register. Sequencer interrupts are cleared by writing a 1 to the corresponding `IN` bit in **ADCISC**. Digital comparator interrupts are cleared by writing a 1 to the **ADC Digital Comparator Interrupt Status and Clear (ADCDCISC)** register.

18.3.2.2 DMA Operation

DMA may be used to increase efficiency by allowing each sample sequencer to operate independently and transfer data without processor intervention or reconfiguration.

The ADC asserts single and burst μ DMA request signals (`dma_sreq` and `dma_req`) to the μ DMA controller based on the FIFO level. The `dma_req` signal is generated when the FIFO in question is half-full (that is, at 4 samples for SS0, 2 samples for SS1 and SS2, and at 1 sample for SS3). If, for example, the **ADCSSCTL0** register has six samples to transfer, a burst of four values occurs followed by two single transfers (`dma_sreq`). The `dma_done` signals (one per sample sequencer) are sent to the ADC to allow for a triggering of `DMAINRn` interrupt bits in the **ADCRIS** register. The μ DMA is enabled for a specific sample sequencer by setting the appropriate `ADENn` bit in the **ADCACTSS** register at offset 0x000.

To use the μ DMA with the ADC module, the application must enable the ADC channel through **DMA Channel Map Select n (DMACHMAPn)** register in the μ DMA.

Refer to the “Micro Direct Memory Access (μ DMA)” on page 708 for more details about programming the μ DMA controller.

18.3.2.3 Prioritization

When sampling events (triggers) happen concurrently, they are prioritized for processing by the values in the **ADC Sample Sequencer Priority (ADCSSPRI)** register. Valid priority values are in the range of 0-3, with 0 being the highest priority and 3 being the lowest. Multiple active sample sequencer units with the same priority do not provide consistent results, so software must ensure that all active sample sequencer units have a unique priority value.

18.3.2.4 Sampling Events

Sample triggering for each sample sequencer is defined in the **ADC Event Multiplexer Select (ADCEMUX)** register. Trigger sources include processor (default), analog comparators, an external signal on a GPIO specified by the **GPIO ADC Control (GPIOADCCTL)** register, a GP Timer, a

PWM generator, and continuous sampling. The processor triggers sampling by setting the SS_x bits in the **ADC Processor Sample Sequence Initiate (ADCPSSI)** register.

Care must be taken when using the continuous sampling trigger. If a sequencer's priority is too high, it is possible to starve other lower priority sequencers. Generally, a sample sequencer using continuous sampling should be set to the lowest priority. Continuous sampling can be used with a digital comparator to cause an interrupt when a particular voltage is seen on an input.

18.3.2.5 Sample and Hold Window Control

The ADC module provides the capability of programming the sample and hold window of each step in a sequence through the **ADC Sample Sequence n Sample and Hold Time (ADCSSTSHn)** register. Each T_{SHn} field can be written with a different sample and hold width, which is represented in ADC clocks. The table below gives the allowed encodings:

Table 18-3. Sample and Hold Width in ADC Clocks

| TSHn Encoding | N_{SH} |
|---------------|----------|
| 0x0 | 4 |
| 0x1 | reserved |
| 0x2 | 8 |
| 0x3 | reserved |
| 0x4 | 16 |
| 0x5 | reserved |
| 0x6 | 32 |
| 0x7 | reserved |
| 0x8 | 64 |
| 0x9 | reserved |
| 0xA | 128 |
| 0xB | reserved |
| 0xC | 256 |
| 0xD-0xF | reserved |

The ADC conversion frequency is a function of the Sample and Hold number, given by the following equation:

$$F_{CONV} = 1 / ((N_{SH} + 12) * T_{ADC})$$

where:

- N_{SH} is the sample and hold width in ADC clocks
- T_{ADC} is the ADC conversion clock period, which is the inverse of the ADC clock frequency F_{ADC}

Now, the maximum allowable external source resistance (R_S) also changes with the value of N_{SH} , as the total settling time of the input circuitry must be fast enough to settle to within the ADC resolution in a single sampling interval. The input circuitry includes the external source resistance as well as the input resistance and capacitance of the ADC (R_{ADC} and C_{ADC}).

The values for R_S and F_{CONV} for varying N_{SH} values, with $F_{ADC}=16\text{MHz}$ and $F_{ADC}=32\text{MHz}$ are given in tables 18-4-a and 18-4-b. The system designer must take into consideration both of these factors for optimal ADC operation.

Table 18-4. R_S and F_{CONV} Values with Varying N_{SH} Values and $F_{ADC} = 16$ MHz

| N_{SH} (Cycles) | 4 | 8 | 16 | 32 | 64 | 128 | 256 |
|------------------------|------|------|------|-------|-------|-------|--------|
| F_{CONV} (Ksps) | 1000 | 800 | 571 | 364 | 211 | 114 | 60 |
| R_S Max (Ω) | 500 | 3500 | 9500 | 21500 | 45500 | 93500 | 189500 |

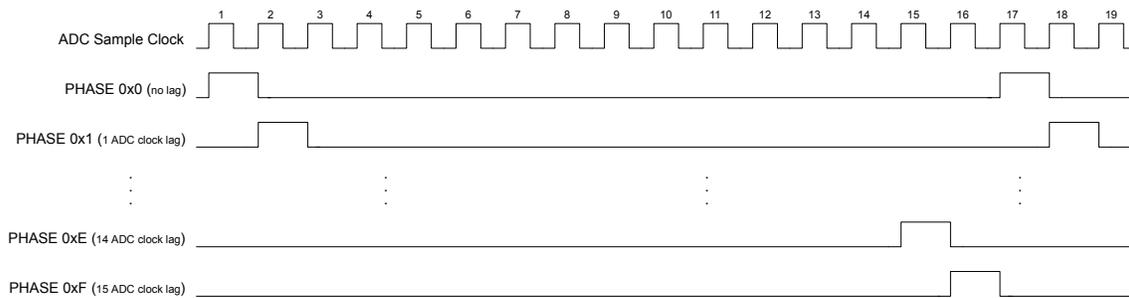

Table 18-5. R_S and F_{CONV} Values with Varying N_{SH} Values and $F_{ADC} = 32$ MHz

| N_{SH} (Cycles) | 4 | 8 | 16 | 32 | 64 | 128 | 256 |
|------------------------|------|------|------|------|-------|-------|-------|
| F_{CONV} (Ksps) | 2000 | 1600 | 1143 | 727 | 421 | 229 | 119 |
| R_S Max (Ω) | 250 | 500 | 3500 | 9500 | 21500 | 45500 | 93500 |

18.3.2.6 Sample Phase Control

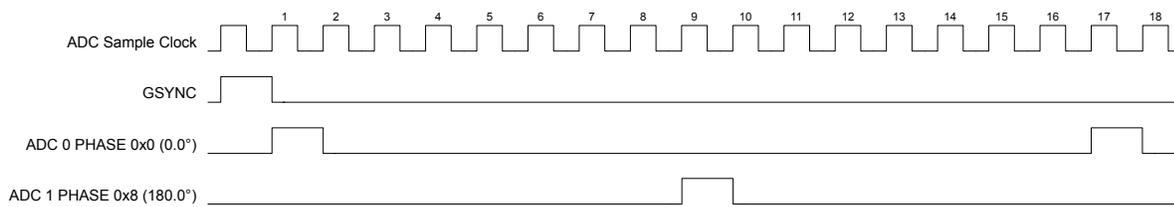

The trigger source for ADC0 and ADC1 may be independent or the two ADC modules may operate from the same trigger source and operate on the same or different inputs. If the converters are running at the same sample rate, they may be configured to start the conversions coincidentally or one ADC may be programmed to lag up to 15 clock cycles relative to the other ADC. The sample time can be delayed from the standard sampling time by programming the $PHASE$ field in the **ADC Sample Phase Control (ADCSPC)** register. Figure 18-3 on page 1210 shows an example of various phase relationships.

Figure 18-3. ADC Sample Phases

This feature can be used to double the sampling rate of an input. Both ADC Module 0 and ADC Module 1 can be programmed to sample the same input. ADC module 0 can sample at the standard position (the $PHASE$ field in the **ADCSPC** register is 0x0). ADC Module 1 can be configured to sample with a phase lag ($PHASE$ is nonzero). For a sample rate of two million samples/second at 16MHz, the $TSHn$ field of all of the sequencer samples of both ADCs must be programmed to 0x0 and the $PHASE$ field of one of the ADC modules must be set to 0x8. The two modules can be synchronized using the $GSYNC$ and $SYNCWAIT$ bits in the **ADC Processor Sample Sequence Initiate (ADCPSSI)** register. Software can then combine the results from the two modules to create a sample rate of two million samples/second at 16MHz as shown in Figure 18-4 on page 1211.

Figure 18-4. Doubling the ADC Sample Rate

Using the **ADCSPC** register, ADC0 and ADC1 may provide a number of interesting applications:

- Coincident continuous sampling of different signals. The sample sequence steps run coincidentally in both converters. In this situation, the TSH_n of matching sample steps of both ADC module sequencers must be the same and the $PHASE$ field must be 0x0 in both ADC module **ADCSPC** registers. The TSH_n field is found in the **ADC Sample Sequence n Sample and Hold Time (ADCSSSTSHn)** register.

- ADC Module 0, **ADCSPC** = 0x0, sampling A_{IN0}

- ADC Module 1, **ADCSPC** = 0x0, sampling A_{IN1}

Note: If two ADCs are configured to sample the same signal, a skew (phase lag) must be added to one of the ADC modules to prevent coincident sampling. Phase lag can be added by programming the $PHASE$ field in the **ADCSPC** register.

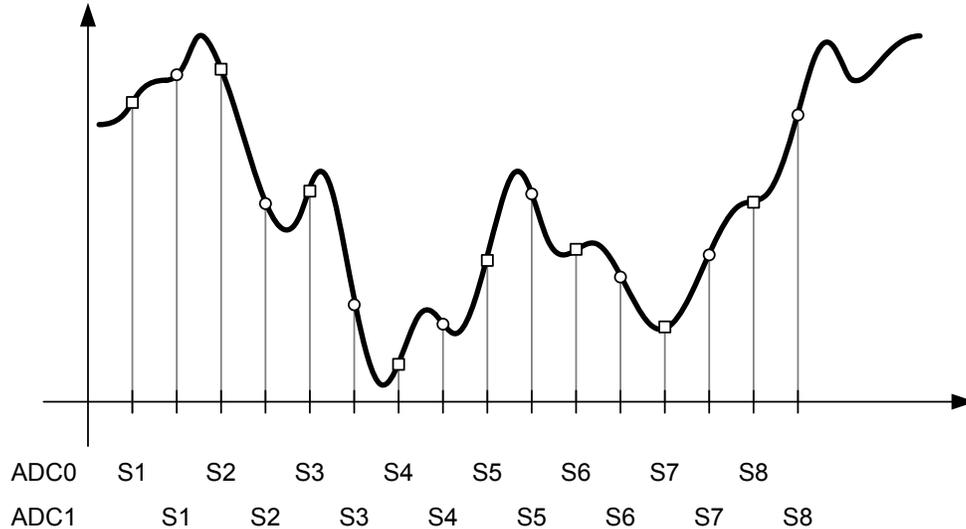

- Skewed sampling of the same signal. The skew is determined by both the TSH_n field in the **ADCSSSTSHn** registers and the $PHASE$ field in the **ADCSPC** register. For the fastest skewed sample rate, all TSH_n fields must be programmed to 0x0. If $TSH_n=0x0$ for all sequencers and the $PHASE$ field of one ADC is 0x8, the configuration doubles the conversion bandwidth of a single input when software combines the results as shown in Figure 18-5 on page 1212.

- ADC Module 0, **ADCSPC** = 0x0, sampling A_{IN0}

- ADC Module 1, **ADCSPC** = 0x8, sampling A_{IN0}

Note that it is not required that the TSH_n fields be the same in a skewed sample. If an application has varying analog input resistance, then TSH_n and $PHASE$ may vary according to operational requirements.

Figure 18-5. Skewed Sampling

18.3.2.7 Module Clocking

The ADC digital block is clocked by the system clock and the ADC analog block is clocked from a separate conversion clock (ADC Clock). The ADC clock frequency can be up to 32 MHz to generate a conversion rate of 2 Msps. A 16 MHz ADC clock provides a 1 Msps sampling rate. There are three sources of the ADC clock:

- Divided PLL VCO. The PLL VCO frequency can be configured to generate up to a 32-MHz clock for a conversion rate of 2 Msps. The **CS** field in the **ADCCC** register must be programmed to 0x0 to select the PLL VCO and the **CLKDIV** field is used to set the appropriate clock divisor for the desired frequency.
- 16 MHz PIOSC. Using the PIOSC provides a conversion rate near 1 Msps. To use the PIOSC to clock the ADC, first power up the PLL and then enable the PIOSC in the **CS** bit field in the **ADCCC** register, then disable the PLL.
- MOSC. The MOSC clock source must be 16 MHz for a 1 Msps conversion rate and 32 MHz for a 2 Msps conversion rate.

The system clock must be at the same frequency or higher than the ADC clock. All ADC modules share the same clock source to facilitate the synchronization of data samples between conversion units, the selection and programming of which is provided by ADC0's **ADCCC** register. The ADC modules do not run at different conversion rates.

18.3.2.8 Busy Status

The **BUSY** bit of the **ADCACTSS** register is used to indicate when the ADC is busy with a current conversion. When there are no triggers pending which may start a new conversion in the immediate cycle or next few cycles, the **BUSY** bit reads as 0. Software must read the status of the **BUSY** bit as clear before disabling the ADC clock by writing to the **Analog-to-Digital Converter Run Mode Clock Gating Control (RCGCADC)** register.

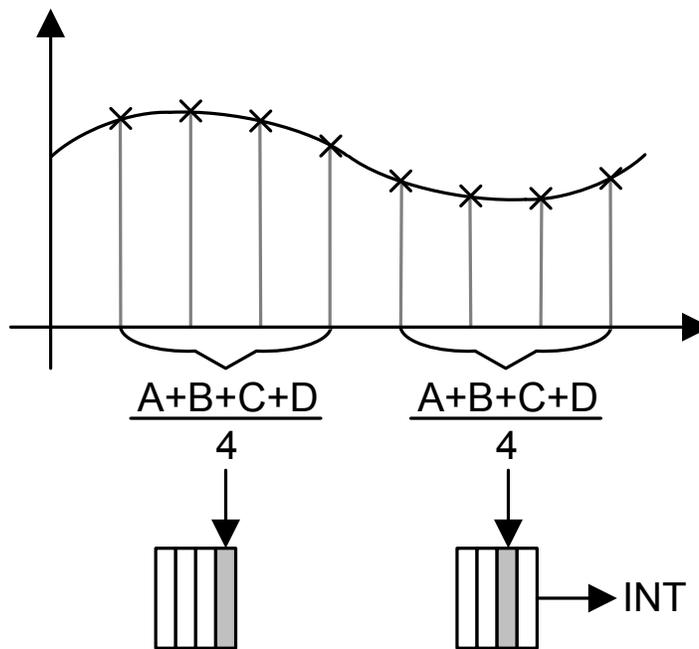

18.3.3 Hardware Sample Averaging Circuit

Higher precision results can be generated using the hardware averaging circuit, however, the improved results are at the cost of throughput. Up to 64 samples can be accumulated and averaged to form a single data entry in the sequencer FIFO. Throughput is decreased proportionally to the number of samples in the averaging calculation. For example, if the averaging circuit is configured to average 16 samples, the throughput is decreased by a factor of 16.

By default the averaging circuit is off, and all data from the converter passes through to the sequencer FIFO. The averaging hardware is controlled by the **ADC Sample Averaging Control (ADCSAC)** register (see page 1256). A single averaging circuit has been implemented, thus all input channels receive the same amount of averaging whether they are single-ended or differential.

Figure 18-6 shows an example in which the **ADCSAC** register is set to 0x2 for 4x hardware oversampling and the **IE1** bit is set for the sample sequence, resulting in an interrupt after the second averaged value is stored in the FIFO.

Figure 18-6. Sample Averaging Example

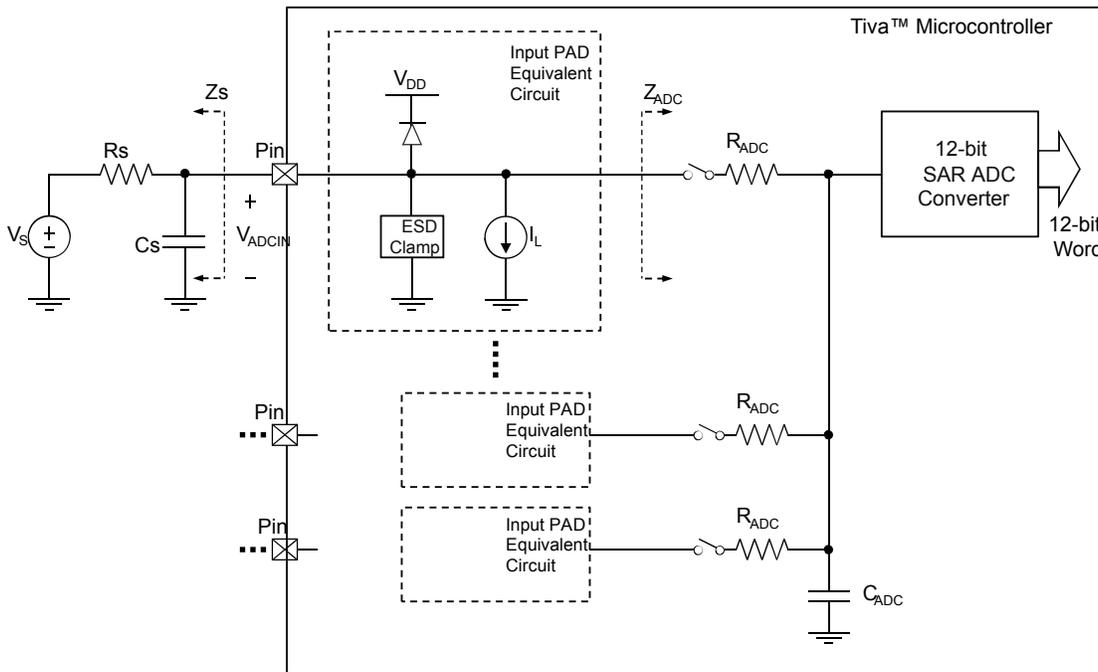

18.3.4 Analog-to-Digital Converter

The Analog-to-Digital Converter (ADC) module uses a Successive Approximation Register (SAR) architecture to deliver a 12-bit, low-power, high-precision conversion value. The successive approximation uses a switched capacitor array to perform the dual functions of sampling and holding the signal as well as providing the 12-bit DAC operation.

Figure 18-7 shows the ADC input equivalency diagram; for parameter values, see “Analog-to-Digital Converter (ADC)” on page 2138.

Figure 18-7. ADC Input Equivalency

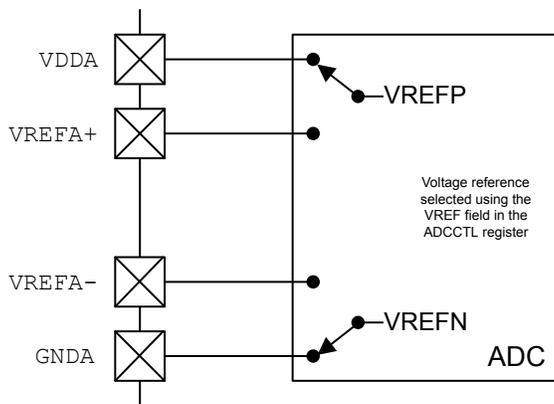

The ADC operates from both the 3.3-V analog and 1.2-V digital power supplies. The ADC clock can be configured to reduce power consumption when ADC conversions are not required (see “System Control” on page 251). The analog inputs are connected to the ADC through specially balanced input paths to minimize the distortion and cross-talk on the inputs. Detailed information on the ADC power supplies and analog inputs can be found in “Analog-to-Digital Converter (ADC)” on page 2138.

18.3.4.1 Voltage Reference

The ADC uses internal signals $VREFP$ and $VREFN$ as references to produce a conversion value from the selected analog input. $VREFP$ can be connected to either $VREFA+$ or $VDDA$ and $VREFN$ can be connected to either $VREFA-$ or $GNDA$ as configured by the $VREF$ bit in the **ADC Control (ADCCTL)** register, as shown in Figure 18-8.

Figure 18-8. ADC Voltage Reference

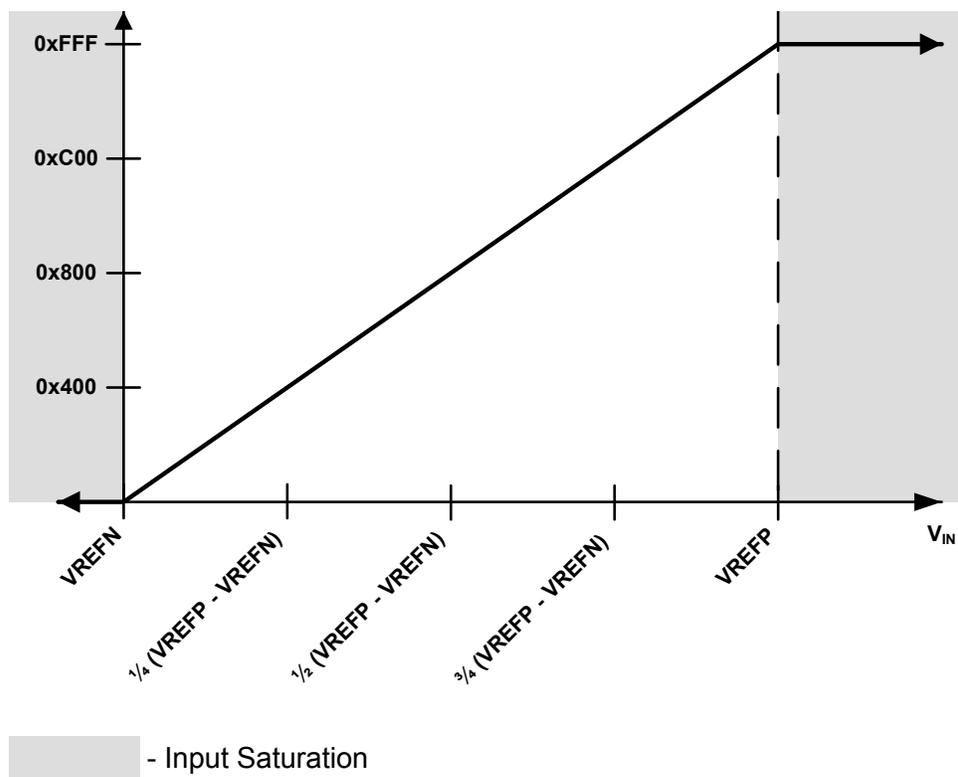

The range of this conversion value is from 0x000 to 0xFFFF. In single-ended-input mode, the 0x000 value corresponds to the voltage level on VREFN; the 0xFFFF value corresponds to the voltage level on VREFP. This configuration results in a resolution that can be calculated using the following equation:

$$\text{mV per ADC code} = (\text{VREFP} - \text{VREFN}) / 4096$$

While the analog input pads can handle voltages beyond this range, the analog input voltages must remain within the limits prescribed by Table 32-44 on page 2138 to produce accurate results. The $V_{\text{REFA}+}$ and $V_{\text{REFA}-}$ specifications define the useful range for the external voltage references on $V_{\text{REFA}+}$ and $V_{\text{REFA}-}$, see Table 32-44 on page 2138. Care must be taken to supply a reference voltage of acceptable quality. Figure 18-9 on page 1215 shows the ADC conversion function of the analog inputs.

Figure 18-9. ADC Conversion Result

18.3.5 Differential Sampling

In addition to traditional single-ended sampling, the ADC module supports differential sampling of two analog input channels. To enable differential sampling, software must set the D_n bit in the **ADCSSCTL0n** register in a step's configuration nibble.

When a sequence step is configured for differential sampling, the input pair to sample must be configured in the **ADCSSMUXn** register. Differential pair 0 samples analog inputs 0 and 1; differential

pair 1 samples analog inputs 2 and 3; and so on (see Table 18-6 on page 1216). The ADC does not support other differential pairings such as analog input 0 with analog input 3.

Table 18-6. Differential Sampling Pairs

| Differential Pair | Analog Inputs |
|-------------------|---------------|
| 0 | 0 and 1 |
| 1 | 2 and 3 |
| 2 | 4 and 5 |
| 3 | 6 and 7 |
| 4 | 8 and 9 |
| 5 | 10 and 11 |
| 6 | 12 and 13 |
| 7 | 14 and 15 |
| 8 | 16 and 17 |
| 9 | 18 and 19 |
| 10 | 20 and 21 |
| 11 | 22 and 23 |

The voltage sampled in differential mode is the difference between the odd and even channels:

- Input Positive Voltage: $V_{IN+} = V_{IN_EVEN}$ (even channel)
- Input Negative Voltage: $V_{IN-} = V_{IN_ODD}$ (odd channel)

The input differential voltage is defined as: $V_{IN_D} = V_{IN+} - V_{IN-}$, therefore:

- If $V_{IN_D} = 0$, then the conversion result = 0x800
- If $V_{IN_D} > 0$, then the conversion result $> 0x800$ (range is 0x800–0xFFF)
- If $V_{IN_D} < 0$, then the conversion result $< 0x800$ (range is 0–0x800)

When using differential sampling, the following definitions are relevant:

- Input Common Mode Voltage: $V_{IN_{CM}} = (V_{IN+} + V_{IN-}) / 2$
- Reference Positive Voltage: V_{REFP}
- Reference Negative Voltage: V_{REFN}
- Reference Differential Voltage: $V_{REF_D} = V_{REFP} - V_{REFN}$
- Reference Common Mode Voltage: $V_{REF_{CM}} = (V_{REFP} + V_{REFN}) / 2$

The following conditions provide optimal results in differential mode:

- Both V_{IN_EVEN} and V_{IN_ODD} must be in the range of (V_{REFP} to V_{REFN}) for a valid conversion result

- The maximum possible differential input swing, or the maximum differential range, is: $-VREF_D$ to $+VREF_D$, so the maximum peak-to-peak input differential signal is $(+VREF_D - -VREF_D) = 2 * VREF_D = 2 * (VREFP - VREFN)$
- In order to take advantage of the maximum possible differential input swing, VIN_{CM} should be very close to $VREF_{CM}$, see Table 32-44 on page 2138.

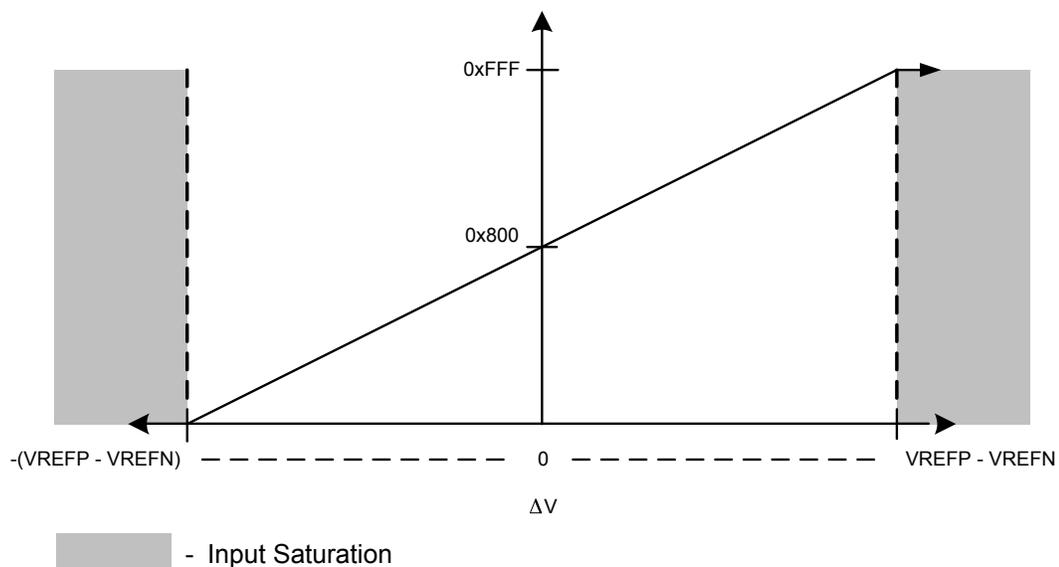

If VIN_{CM} is not equal to $VREF_{CM}$, the differential input signal may clip at either maximum or minimum voltage, because either single ended input can never be larger than $VREFP$ or smaller than $VREFN$, and it is not possible to achieve full swing. Thus any difference in common mode between the input voltage and the reference voltage limits the differential dynamic range of the ADC.

Because the maximum peak-to-peak differential signal voltage is $2 * (VREFP - VREFN)$, the ADC codes are interpreted as:

$$\text{mV per ADC code} = (2 * (VREFP - VREFN)) / 4096$$

Figure 18-10 shows how the differential voltage, ΔV , is represented in ADC codes.

Figure 18-10. Differential Voltage Representation

18.3.6 Internal Temperature Sensor

The temperature sensor serves two primary purposes: 1) to notify the system that internal temperature is too high or low for reliable operation and 2) to provide temperature measurements for calibration of the Hibernate module RTC trim value.

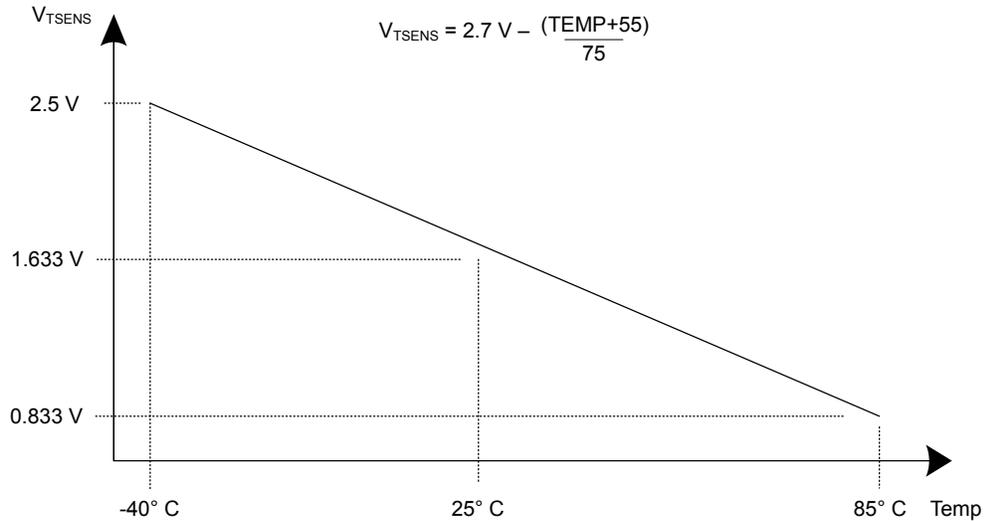

The temperature sensor does not have a separate enable, because it also contains the bandgap reference and must always be enabled. The reference is supplied to other analog modules; not just the ADC. In addition, the temperature sensor has a second power-down input in the 3.3 V domain which provides control by the Hibernation module.

The internal temperature sensor converts a temperature measurement into a voltage. This voltage value, V_{TSENS} , is given by the following equation (where TEMP is the temperature in °C):

$$V_{\text{TSSENS}} = 2.7 - ((\text{TEMP} + 55) / 75)$$

This relation is shown in Figure 18-11 on page 1218.

Figure 18-11. Internal Temperature Sensor Characteristic

The temperature sensor reading can be sampled in a sample sequence by setting the TS_n bit in the **ADCSSTLn** register. The sample and hold width should be configured for at least 16 ADC clocks using the **ADCSSTSHn** register. The temperature reading from the temperature sensor can also be given as a function of the ADC value. The following formula calculates temperature (TEMP in °C) based on the ADC reading (ADC_{CODE} , given as an unsigned decimal number from 0 to 4095) and the maximum ADC voltage range ($V_{\text{REFP}} - V_{\text{REFN}}$):

$$\text{TEMP} = 147.5 - ((75 * (V_{\text{REFP}} - V_{\text{REFN}}) * \text{ADC}_{\text{CODE}}) / 4096)$$

18.3.7 Digital Comparator Unit

An ADC is commonly used to sample an external signal and to monitor its value to ensure that it remains in a given range. To automate this monitoring procedure and reduce the amount of processor overhead that is required, each module provides eight digital comparators.

Conversions from the ADC that are sent to the digital comparators are compared against the user programmable limits in the **ADC Digital Comparator Range (ADCDCMPn)** registers. The ADC can be configured to generate an interrupt depending on whether the ADC is operating within the low, mid or high-band region configured in the **ADCDCMPn** bit fields. The digital comparators four operational modes (Once, Always, Hysteresis Once, Hysteresis Always) can be additionally applied to the interrupt configuration.

18.3.7.1 Output Functions

ADC conversions can either be stored in the ADC Sample Sequence FIFOs or compared using the digital comparator resources as defined by the SNDCOP bits in the **ADC Sample Sequence n Operation (ADCSOPn)** register. These selected ADC conversions are used by their respective

digital comparator to monitor the external signal. Each comparator has two possible output functions: processor interrupts and triggers.

Each function has its own state machine to track the monitored signal. Even though the interrupt and trigger functions can be enabled individually or both at the same time, the same conversion data is used by each function to determine if the right conditions have been met to assert the associated output.

Interrupts

The digital comparator interrupt function is enabled by setting the **CIE** bit in the **ADC Digital Comparator Control (ADCDCCTLn)** register. This bit enables the interrupt function state machine to start monitoring the incoming ADC conversions. When the appropriate set of conditions is met, and the **DCONSSx** bit is set in the **ADCIM** register, an interrupt is sent to the interrupt controller.

Note: For a 1 to 2 Msps rate, as the system clock frequency approaches the ADC clock frequency, it is recommended that the application use the μ DMA to store conversion data from the FIFO to memory before processing rather than an interrupt-driven single data read. Using the μ DMA to store multiple samples before interrupting the processor amortizes interrupt overhead across multiple transfers and prevents loss of sample data.

Note: Only a single **DCONSSn** bit should be set at any given time. Setting more than one of these bits results in the **INRDC** bit from the **ADCRIS** register being masked, and no interrupt is generated on any of the sample sequencer interrupt lines. It is recommended that when interrupts are used, they are enabled on alternating samples or at the end of the sample sequence.

Triggers

The digital comparator trigger function is enabled by setting the **CTE** bit in the **ADCDCCTLn** register. This bit enables the trigger function state machine to start monitoring the incoming ADC conversions. When the appropriate set of conditions is met, the corresponding digital comparator trigger to the PWM module is asserted.

18.3.7.2 Operational Modes

Four operational modes are provided to support a broad range of applications and multiple possible signaling requirements: Always, Once, Hysteresis Always, and Hysteresis Once. The operational mode is selected using the **CIM** or **CTM** field in the **ADCDCCTLn** register.

Always Mode

In the Always operational mode, the associated interrupt or trigger is asserted whenever the ADC conversion value meets its comparison criteria. The result is a string of assertions on the interrupt or trigger while the conversions are within the appropriate range.

Once Mode

In the Once operational mode, the associated interrupt or trigger is asserted whenever the ADC conversion value meets its comparison criteria, and the previous ADC conversion value did not. The result is a single assertion of the interrupt or trigger when the conversions are within the appropriate range.

Hysteresis-Always Mode

The Hysteresis-Always operational mode can only be used in conjunction with the low-band or high-band regions because the mid-band region must be crossed and the opposite region entered to clear the hysteresis condition. In the Hysteresis-Always mode, the associated interrupt or trigger

is asserted in the following cases: 1) the ADC conversion value meets its comparison criteria or 2) a previous ADC conversion value has met the comparison criteria, and the hysteresis condition has not been cleared by entering the opposite region. The result is a string of assertions on the interrupt or trigger that continue until the opposite region is entered.

Hysteresis-Once Mode

The Hysteresis-Once operational mode can only be used in conjunction with the low-band or high-band regions because the mid-band region must be crossed and the opposite region entered to clear the hysteresis condition. In the Hysteresis-Once mode, the associated interrupt or trigger is asserted only when the ADC conversion value meets its comparison criteria, the hysteresis condition is clear, and the previous ADC conversion did not meet the comparison criteria. The result is a single assertion on the interrupt or trigger.

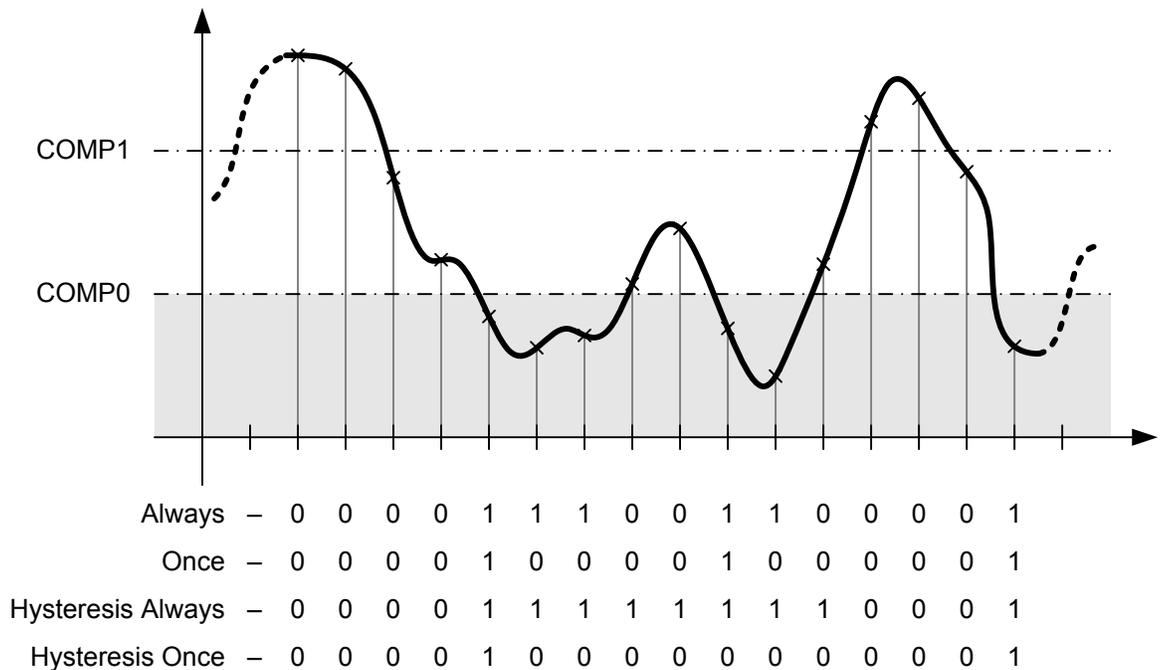

18.3.7.3 Function Ranges

The two comparison values, `COMP0` and `COMP1`, in the **ADC Digital Comparator Range (ADCDCMPn)** register effectively break the conversion area into three distinct regions. These regions are referred to as the low-band (less than `COMP0`), mid-band (greater than `COMP0` but less than or equal to `COMP1`), and high-band (greater than or equal to `COMP1`) regions. `COMP0` and `COMP1` may be programmed to the same value, effectively creating two regions, but `COMP1` must always be greater than or equal to the value of `COMP0`. A `COMP1` value that is less than `COMP0` generates unpredictable results.

Low-Band Operation

To operate in the low-band region, the `CIC` field or the `CTC` field in the **ADCDCCTLn** register must be programmed to `0x0`. This setting causes interrupts or triggers to be generated in the low-band region as defined by the programmed operational mode. An example of the state of the interrupt/trigger signal in the low-band region for each of the operational modes is shown in Figure 18-12 on page 1221. Note that a "0" in a column following the operational mode name (Always, Once, Hysteresis Always, and Hysteresis Once) indicates that the interrupt or trigger signal is deasserted and a "1" indicates that the signal is asserted.

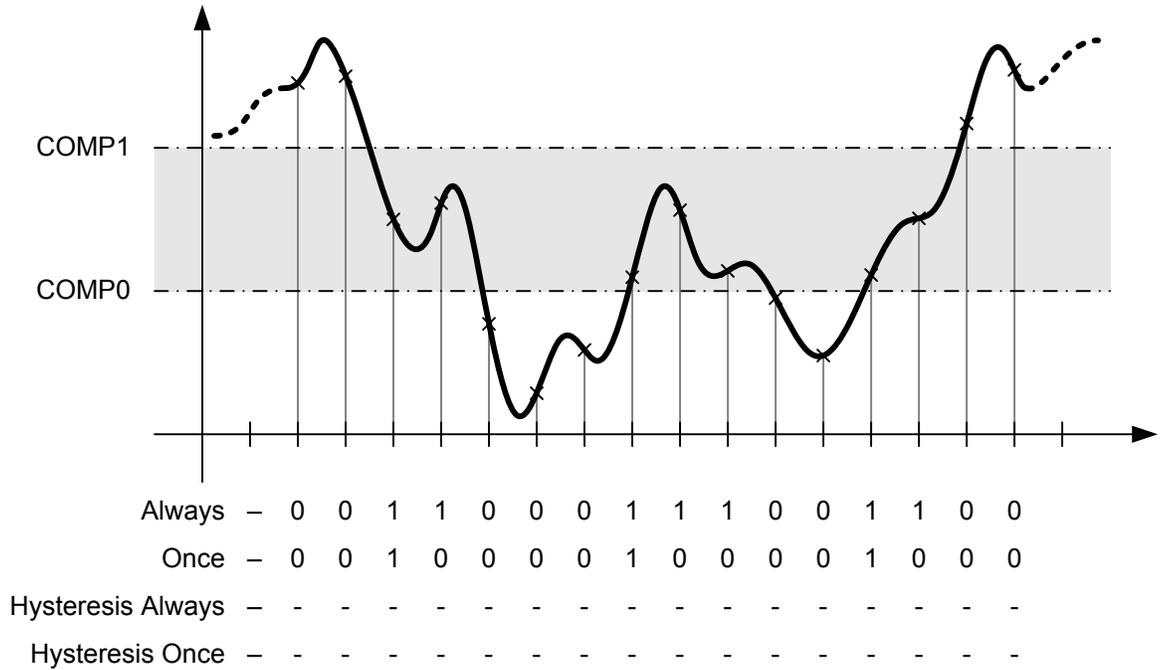

Figure 18-12. Low-Band Operation (CIC=0x0 and/or CTC=0x0)

Mid-Band Operation

To operate in the mid-band region, the **CIC** field or the **CTC** field in the **ADCDCCTLn** register must be programmed to 0x1. This setting causes interrupts or triggers to be generated in the mid-band region according to the operation mode. Only the Always and Once operational modes are available in the mid-band region. An example of the state of the interrupt/trigger signal in the mid-band region for each of the allowed operational modes is shown in Figure 18-13 on page 1222. Note that a "0" in a column following the operational mode name (Always or Once) indicates that the interrupt or trigger signal is deasserted and a "1" indicates that the signal is asserted.

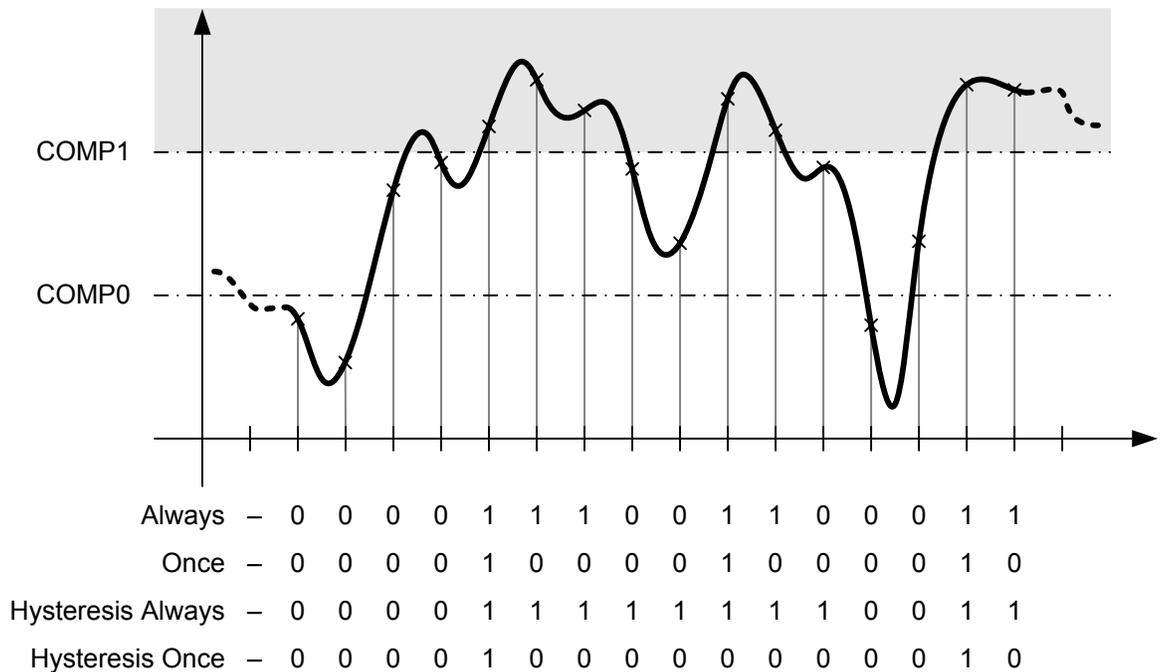

Figure 18-13. Mid-Band Operation (CIC=0x1 and/or CTC=0x1)

High-Band Operation

To operate in the high-band region, the `CIC` field or the `CTC` field in the `ADDCCTLn` register must be programmed to `0x3`. This setting causes interrupts or triggers to be generated in the high-band region according to the operation mode. An example of the state of the interrupt/trigger signal in the high-band region for each of the allowed operational modes is shown in Figure 18-14 on page 1223. Note that a "0" in a column following the operational mode name (Always, Once, Hysteresis Always, and Hysteresis Once) indicates that the interrupt or trigger signal is deasserted and a "1" indicates that the signal is asserted.

Figure 18-14. High-Band Operation (CIC=0x3 and/or CTC=0x3)

18.4 Initialization and Configuration

18.4.1 Module Initialization

Initialization of the ADC module is a simple process with very few steps: enabling the clock to the ADC, disabling the analog isolation circuit associated with all inputs that are to be used, and reconfiguring the sample sequencer priorities (if needed).

The initialization sequence for the ADC is as follows:

1. Enable the ADC clock using the **RCGCADC** register (see page 413).
2. Enable the clock to the appropriate GPIO modules via the **RCGCGPIO** register (see page 399). To find out which GPIO ports to enable, refer to “Signal Description” on page 1205.
3. Set the GPIO **AFSEL** bits for the ADC input pins (see page 803). To determine which GPIOs to configure, see Table 31-4 on page 2064.
4. Configure the **AIN_x** signals to be analog inputs by clearing the corresponding **DEN** bit in the **GPIO Digital Enable (GPIODEN)** register (see page 814).
5. Disable the analog isolation circuit for all ADC input pins that are to be used by writing a 1 to the appropriate bits of the **GPIOAMSEL** register (see page 819) in the associated GPIO block.
6. If required by the application, reconfigure the sample sequencer priorities in the **ADCSSPRI** register. The default configuration has Sample Sequencer 0 with the highest priority and Sample Sequencer 3 as the lowest priority.

18.4.2 Sample Sequencer Configuration

Configuration of the sample sequencers is slightly more complex than the module initialization because each sample sequencer is completely programmable.

The configuration for each sample sequencer should be as follows:

1. Ensure that the sample sequencer is disabled by clearing the corresponding `ASENn` bit in the **ADCACTSS** register. Programming of the sample sequencers is allowed without having them enabled. Disabling the sequencer during programming prevents erroneous execution if a trigger event were to occur during the configuration process.
2. Configure the trigger event for the sample sequencer in the **ADCEMUX** register.
3. When using a PWM generator as the trigger source, use the **ADC Trigger Source Select (ADCTSSEL)** register to specify in which PWM module the generator is located. The default register reset selects PWM module 0 for all generators.
4. For each sample in the sample sequence, configure the corresponding input source in the **ADCSSMUX_n** and **ADCSEMUX_n** registers.
5. For each sample in the sample sequence, configure the sample control bits in the corresponding nibble in the **ADCSSCTL_n** register. When programming the last nibble, ensure that the `END` bit is set. Failure to set the `END` bit causes unpredictable behavior.
6. If interrupts are to be used, set the corresponding `MASK` bit in the **ADCIM** register.
7. Enable the sample sequencer logic by setting the corresponding `ASENn` bit in the **ADCACTSS** register.

18.5 Register Map

Table 18-7 on page 1224 lists the ADC registers. The offset listed is a hexadecimal increment to the register's address, relative to that ADC module's base address of:

- ADC0: 0x4003.8000
- ADC1: 0x4003.9000

Note that the ADC module clock must be enabled before the registers can be programmed (see page 413). There must be a delay of 3 system clocks after the ADC module clock is enabled before any ADC module registers are accessed.

Table 18-7. ADC Register Map

| Offset | Name | Type | Reset | Description | See page |
|--------|----------|------|-------------|--------------------------------|----------|

18.6 Register Descriptions

The remainder of this section lists and describes the ADC registers, in numerical order by address offset.

Register 1: ADC Active Sample Sequencer (ADCACTSS), offset 0x000

This register controls the activation of the sample sequencers. Each sample sequencer can be enabled or disabled independently.

ADC Active Sample Sequencer (ADCACTSS)

ADC0 base: 0x4003.8000
 ADC1 base: 0x4003.9000
 Offset 0x000
 Type RW, reset 0x0000.0000

| | | | | | | | | | | | | | | | | |
|-------|----------|----|----|----|-------|-------|-------|-------|----------|----|----|----|-------|-------|-------|-------|
| | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | reserved | | | | | | | | | | | | | | | BUSY |
| Type | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | reserved | | | | ADEN3 | ADEN2 | ADEN1 | ADEN0 | reserved | | | | ASEN3 | ASEN2 | ASEN1 | ASEN0 |
| Type | RO | RO | RO | RO | RW | RW | RW | RW | RO | RO | RO | RO | RW | RW | RW | RW |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|-------|---|
| 31:17 | reserved | RO | 0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 16 | BUSY | RO | 0 | ADC Busy Value Description 0 ADC is idle 1 ADC is busy |
| 15:12 | reserved | RO | 0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 11 | ADEN3 | RW | 0 | ADC SS3 DMA Enable Value Description 0 DMA for Sample Sequencer 3 is disabled. 1 DMA for Sample Sequencer 3 is enabled. |
| 10 | ADEN2 | RW | 0 | ADC SS2 DMA Enable Value Description 0 DMA for Sample Sequencer 2 is disabled. 1 DMA for Sample Sequencer 2 is enabled. |

Note: In order to use the `BUSY` bit, the **ADC Event Multiplexer Select (ADCEMUX)** register must be programmed such that no trigger is selected (bit field encoding is 0xE). The NEVER encoding in the **ADCEMUX** register allows the ADC to safely be put in Deep-Sleep mode.

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|-------|---|
| 9 | ADEN1 | RW | 0 | ADC SS1 DMA Enable Value Description 0 DMA for Sample Sequencer 1 is disabled. 1 DMA for Sample Sequencer 1 is enabled. |
| 8 | ADEN0 | RW | 0 | ADC SS1 DMA Enable Value Description 0 DMA for Sample Sequencer 1 is disabled. 1 DMA for Sample Sequencer 1 is enabled. |
| 7:4 | reserved | RO | 0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 3 | ASEN3 | RW | 0 | ADC SS3 Enable Value Description 0 Sample Sequencer 3 is disabled. 1 Sample Sequencer 3 is enabled. |
| 2 | ASEN2 | RW | 0 | ADC SS2 Enable Value Description 0 Sample Sequencer 2 is disabled. 1 Sample Sequencer 2 is enabled. |
| 1 | ASEN1 | RW | 0 | ADC SS1 Enable Value Description 0 Sample Sequencer 1 is disabled. 1 Sample Sequencer 1 is enabled. |
| 0 | ASEN0 | RW | 0 | ADC SS0 Enable Value Description 0 Sample Sequencer 0 is disabled. 1 Sample Sequencer 0 is enabled. |

Register 2: ADC Raw Interrupt Status (ADCRIS), offset 0x004

This register shows the status of the raw interrupt signal of each sample sequencer. These bits may be polled by software to look for interrupt conditions without sending the interrupts to the interrupt controller.

ADC Raw Interrupt Status (ADCRIS)

ADC0 base: 0x4003.8000
 ADC1 base: 0x4003.9000
 Offset 0x004
 Type RO, reset 0x0000.0000

| | | | | | | | | | | | | | | | | |

| | | | | 1 A sample has completed conversion and the respective ADCSSCTL0 I_{En} bit is set, enabling a raw interrupt. |
| | | | | This bit is cleared by writing a 1 to the IN0 bit in the ADCISC register. |

Register 3: ADC Interrupt Mask (ADCIM), offset 0x008

This register controls whether the sample sequencer and digital comparator raw interrupt signals are sent to the interrupt controller. Each raw interrupt signal can be masked independently.

Note: For a 1 to 2 Msps rate, as the system clock frequency approaches the ADC clock frequency, it is recommended that the application use the μ DMA to store conversion data from the FIFO to memory before processing rather than an interrupt-driven single data read. Using the μ DMA to store multiple samples before interrupting the processor amortizes interrupt overhead across multiple transfers and prevents loss of sample data.

Note: Only a single $DCONSS_n$ bit should be set at any given time. Setting more than one of these bits results in the $INRDC$ bit from the **ADCRIS** register being masked, and no interrupt is generated on any of the sample sequencer interrupt lines. It is recommended that when interrupts are used, they are enabled on alternating samples or at the end of the sample sequence.

Register 4: ADC Interrupt Status and Clear (ADCISC), offset 0x00C

This register provides the mechanism for clearing sample sequencer interrupt conditions and shows the status of interrupts generated by the sample sequencers and the digital comparators which have been sent to the interrupt controller. When read, each bit field is the logical AND of the respective **INR** and **MASK** bits. Sample sequencer interrupts are cleared by writing a 1 to the corresponding bit position. Digital comparator interrupts are cleared by writing a 1 to the appropriate bits in the **ADCDCISC** register. If software is polling the **ADCRIS** instead of generating interrupts, the sample sequence **INR_n** bits are still cleared via the **ADCISC** register, even if the **IN_n** bit is not set.

Register 8: ADC Trigger Source Select (ADCTSSEL), offset 0x01C

If a PWM Generator n is selected as a trigger source through the EM_n bit field in the **ADC Event Multiplexer Select (ADCEMUX)** register, the **ADCTSSEL** register is programmed to identify in which PWM module instance the generator creating the trigger is located. The register resets to 0x0000.0000, which selects PWM module 0 for all generators. Note that field PS_3 selects the PWM module that maps to Generator 3; PS_2 selects the PWM module that maps to Generator 2, and so on.

Register 10: ADC Sample Phase Control (ADCSPC), offset 0x024

The **ADC Sample Phase Control (ADCSPC)** register is used to insert a delay in ADC module sampling. This feature can be used with the `SYNCWAIT` and `GSYNC` bit in the **ADCPSSI** register to provide concurrent sampling of two different signals by two different ADC modules or skewed sampling of two ADC modules to increase the effective sampling rate. For concurrent sampling, the `PHASE` field of each ADC module must be the same and the sample and hold times (`TSHn`) for the matching sample steps of each ADC must be the same. For example, both ADC0 and ADC1 would program `PHASE = 0x0` in the **ADCSPC** register and might both have the following configuration for their **ADCSSTSH0** register:

- `TSH7=0x4`
- `TSH6=0x2`
- `TSH5=0x2`
- `TSH4=0x8`
- `TSH3=0x6`
- `TSH2=0x2`
- `TSH1=0x4`
- `TSH0=0x2`

For skewed sampling with a consistent phase lag, the `TSHn` field in the **ADCSSTSH_n** register must be the same for all sample steps of an ADC and for both ADC Modules. The desired lag can be calculated by adding the sample and hold time (`TSHn`) to the twelve clock conversion time to determine the total number of clocks in a sample period. For example to create a 180.0° phase lag, the `PHASE` of the lagging ADC is calculated as:

$$\text{PHASE} = (\text{TSH}_n + 12)/2, \text{ where } \text{TSH}_n \text{ is in ADC_Clocks}$$

For situations where a predictable phase lag is not required, sample and hold times (`TSHn`) of ADC modules can vary.

Note: Care should be taken when the `PHASE` field is non-zero, as the resulting delay in sampling the `AINx` input may result in undesirable system consequences. The time from ADC trigger to sample is increased and could make the response time longer than anticipated. The added latency could have ramifications in the system design. Designers should carefully consider the impact of this delay.

ADC Sample Phase Control (ADCSPC)

Register 11: ADC Processor Sample Sequence Initiate (ADCPSSI), offset 0x028

This register provides a mechanism for application software to initiate sampling in the sample sequencers. Sample sequences can be initiated individually or in any combination. When multiple sequences are triggered simultaneously, the priority encodings in **ADCSSPRI** dictate execution order.

This register also provides a means to configure and then initiate concurrent sampling on all ADC modules. To do this, the first ADC module should be configured. The **ADCPSSI** register for that module should then be written. The appropriate **SS** bits should be set along with the **SYNCWAIT** bit. Additional ADC modules should then be configured following the same procedure. Once the final ADC module is configured, its **ADCPSSI** register should be written with the appropriate **SS** bits set along with the **GSYNC** bit. All of the ADC modules then begin concurrent sampling according to their configuration.

Register 12: ADC Sample Averaging Control (ADCSAC), offset 0x030

This register controls the amount of hardware averaging applied to conversion results. The final conversion result stored in the FIFO is averaged from 2^{AVG} consecutive ADC samples at the specified ADC speed. If AVG is 0, the sample is passed directly through without any averaging. If AVG=6, then 64 consecutive ADC samples are averaged to generate one result in the sequencer FIFO. An AVG=7 provides unpredictable results.

ADC Sample Averaging Control (ADCSAC)

ADC0 base: 0x4003.8000

Register 14: ADC Control (ADCCTL), offset 0x038

This register configures the voltage reference. The voltage references for the conversion can be VREFA+ and VREFA- or VDDA and GNDA. Note that values set in this register apply to all ADC modules, it is not possible to set one module to use internal references and another to use external references.

Register 15: ADC Sample Sequence Input Multiplexer Select 0 (ADCSSMUX0), offset 0x040

This register, along with the **ADCSSSEMUX0** register, defines the analog input configuration for each sample in a sequence executed with Sample Sequencer 0. If the corresponding **EMUX_n** bit in the **ADCSSSEMUX0** register is set, the **MUX_n** field in this register selects from **AIN[23:16]**. When the corresponding **EMUX_n** bit is clear, the **MUX_n** field selects from **AIN[15:0]**. This register is 32 bits wide and contains information for eight possible samples.

Note: Channels **AIN[31:24]** do not exist on this microcontroller. Configuring **MUX_n** to be 0x8-0xF when the corresponding **EMUX_n** bit is set results in undefined behavior.

ADC Sample Sequence Input Multiplexer Select 0 (ADCSSMUX0)

ADC0 base: 0x4003.8000
 ADC1 base: 0x4003.9000
 Offset 0x040
 Type RW, reset 0x0000.0000

| Bit/Field | Name | Type | Reset | Description |
|-----------|------|------|-------|---|
| 31:28 | MUX7 | RW | 0x0 | <p>8th Sample Input Select</p> <p>The MUX7 field is used during the eighth sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion. The value set here indicates the corresponding pin, for example, a value of 0x1 when EMUX7 is clear indicates the input is AIN1. A value of 0x1 when EMUX7 is set indicates the input is AIN17.</p> <p>If differential sampling is enabled (the D7 bit in the ADCSSCTL0 register is set), this field must be set to the pair number "i", where the paired inputs are "2i and 2i+1".</p> |
| 27:24 | MUX6 | RW | 0x0 | <p>7th Sample Input Select</p> <p>The MUX6 field is used during the seventh sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion.</p> |
| 23:20 | MUX5 | RW | 0x0 | <p>6th Sample Input Select</p> <p>The MUX5 field is used during the sixth sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion.</p> |
| 19:16 | MUX4 | RW | 0x0 | <p>5th Sample Input Select</p> <p>The MUX4 field is used during the fifth sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion.</p> |

| Bit/Field | Name | Type | Reset | Description |
|-----------|------|------|-------|--|
| 15:12 | MUX3 | RW | 0x0 | 4th Sample Input Select The MUX3 field is used during the fourth sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion. |
| 11:8 | MUX2 | RW | 0x0 | 3rd Sample Input Select The MUX2 field is used during the third sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion. |
| 7:4 | MUX1 | RW | 0x0 | 2nd Sample Input Select The MUX1 field is used during the second sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion. |
| 3:0 | MUX0 | RW | 0x0 | 1st Sample Input Select The MUX0 field is used during the first sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion. |

Register 16: ADC Sample Sequence Control 0 (ADCSSCTL0), offset 0x044

This register contains the configuration information for each sample for a sequence executed with a sample sequencer. When configuring a sample sequence, the `END` bit must be set for the final sample, whether it be after the first sample, eighth sample, or any sample in between. This register is 32 bits wide and contains information for eight possible samples.

Register 17: ADC Sample Sequence Result FIFO 0 (ADCSSFIFO0), offset 0x048

Register 18: ADC Sample Sequence Result FIFO 1 (ADCSSFIFO1), offset 0x068

Register 19: ADC Sample Sequence Result FIFO 2 (ADCSSFIFO2), offset 0x088

Register 20: ADC Sample Sequence Result FIFO 3 (ADCSSFIFO3), offset 0x0A8

Important: This register is read-sensitive. See the register description for details.

This register contains the conversion results for samples collected with the sample sequencer (the **ADCSSFIFO0** register is used for Sample Sequencer 0, **ADCSSFIFO1** for Sequencer 1, **ADCSSFIFO2** for Sequencer 2, and **ADCSSFIFO3** for Sequencer 3). Reads of this register return conversion result data in the order sample 0, sample 1, and so on, until the FIFO is empty. If the FIFO is not properly handled by software, overflow and underflow conditions are registered in the **ADCOSTAT** and **ADCUSTAT** registers.

ADC Sample Sequence Result FIFO n (ADCSSFIFO_n)

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x048

Type RO, reset -

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|----------|---|
| 31:12 | reserved | RO | 0x0000.0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 11:0 | DATA | RO | - | Conversion Result Data |

Register 21: ADC Sample Sequence FIFO 0 Status (ADCSSFSTAT0), offset 0x04C

Register 22: ADC Sample Sequence FIFO 1 Status (ADCSSFSTAT1), offset 0x06C

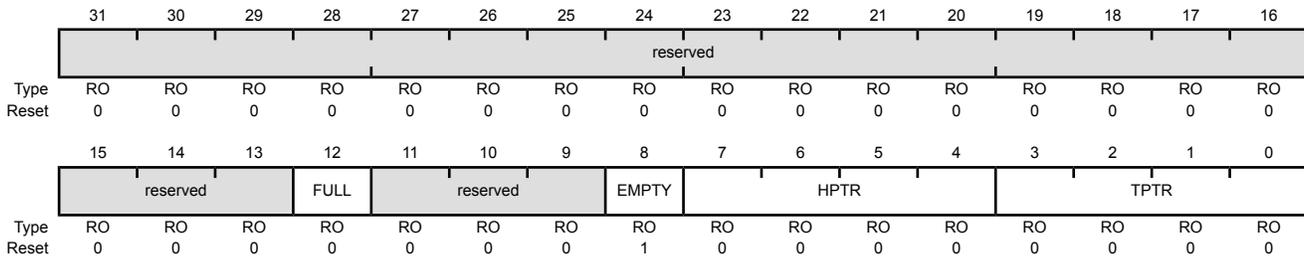

Register 23: ADC Sample Sequence FIFO 2 Status (ADCSSFSTAT2), offset 0x08C

Register 24: ADC Sample Sequence FIFO 3 Status (ADCSSFSTAT3), offset 0x0AC

This register provides a window into the sample sequencer, providing full/empty status information as well as the positions of the head and tail pointers. The reset value of 0x100 indicates an empty FIFO with the head and tail pointers both pointing to index 0. The **ADCSSFSTAT0** register provides status on FIFO0, which has 8 entries; **ADCSSFSTAT1** on FIFO1, which has 4 entries; **ADCSSFSTAT2** on FIFO2, which has 4 entries; and **ADCSSFSTAT3** on FIFO3 which has a single entry.

Register 27: ADC Sample Sequence Extended Input Multiplexer Select 0 (ADCSSEMUX0), offset 0x058

This register, along with the **ADCSSMUX0** register, defines the analog input configuration for each sample in a sequence executed with Sample Sequencer 0. If a bit in this register is set, the corresponding **MUX_n** field in the **ADCSSMUX0** register selects from **AIN[23:16]**. When a bit in this register is clear, the corresponding **MUX_n** field selects from **AIN[15:0]**. This register is 32 bits wide and contains information for eight possible samples.

Note that this register is not used when the differential channel designation is used (the **D_n** bit is set in the **ADCSSCTL0** register) because the **ADCSSMUX0** register can select all the available pairs.

ADC Sample Sequence Extended Input Multiplexer Select 0 (ADCSSEMUX0)

Register 28: ADC Sample Sequence 0 Sample and Hold Time (ADCSSTSH0), offset 0x05C

This register controls the sample period size for each sample of sequencer 0. Each sample and hold period select specifies the time allocated to the sample and hold circuit as shown by the encodings in Table 18-3 on page 1209.

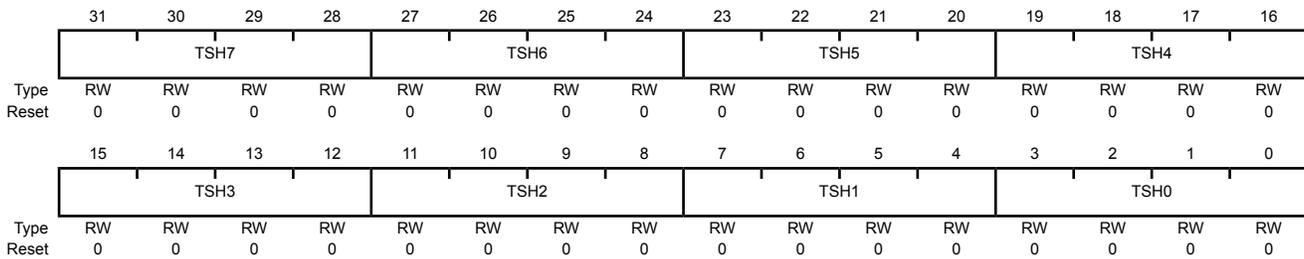

Note: If sampling the internal temperature sensor, the sample and hold width should be at least 16 ADC clocks ($T_{SHn} = 0x4$).

Table 18-8. Sample and Hold Width in ADC Clocks

| TSHn Encoding | N _{SH} |
|---------------|-----------------|
| 0x0 | 4 |
| 0x1 | reserved |
| 0x2 | 8 |

| 3:0 | TSH0 | RW | 0x0 | 1st Sample and Hold Period Select The TSH0 field is used during the first sample of a sequence executed with the sample sequencer. |

Register 29: ADC Sample Sequence Input Multiplexer Select 1 (ADCSSMUX1), offset 0x060

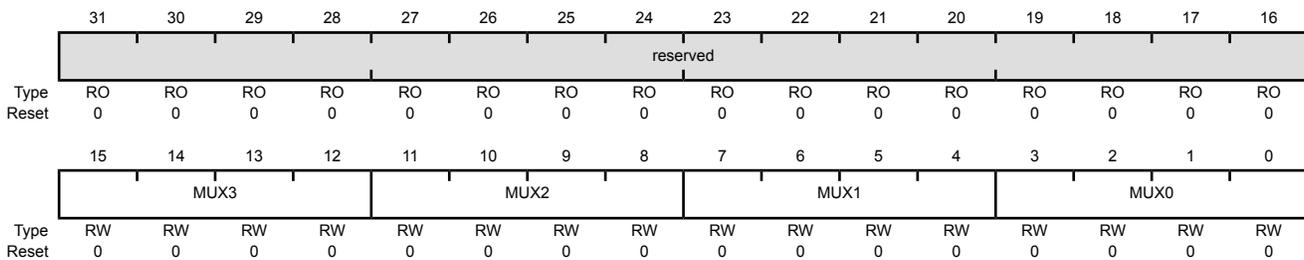

Register 30: ADC Sample Sequence Input Multiplexer Select 2 (ADCSSMUX2), offset 0x080

This register, along with the **ADCSSMUX1** or **ADCSSMUX2** register, defines the analog input configuration for each sample in a sequence executed with Sample Sequencer 1 or 2. If the corresponding **EMUX_n** bit in the **ADCSSMUX1** or **ADCSSMUX2** register is set, the **MUX_n** field in this register selects from **AIN[23:16]**. When the corresponding **EMUX_n** bit is clear, the **MUX_n** field selects from **AIN[15:0]**. These registers are 16 bits wide and contain information for four possible samples. See the **ADCSSMUX0** register on page 1260 for detailed bit descriptions. The **ADCSSMUX1** register affects Sample Sequencer 1 and the **ADCSSMUX2** register affects Sample Sequencer 2.

Note: Channels **AIN[31:24]** do not exist on this microcontroller. Configuring **MUX_n** to be 0x8-0xF when the corresponding **EMUX_n** bit is set results in undefined behavior.

ADC Sample Sequence Input Multiplexer Select n (ADCSSMUXn)

ADC0 base: 0x4003.8000
 ADC1 base: 0x4003.9000
 Offset 0x060
 Type RW, reset 0x0000.0000

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|--------|---|
| 31:16 | reserved | RO | 0x0000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 15:12 | MUX3 | RW | 0x0 | 4th Sample Input Select |
| 11:8 | MUX2 | RW | 0x0 | 3rd Sample Input Select |

| 3:0 | MUX0 | RW | 0x0 | 1st Sample Input Select |

Register 31: ADC Sample Sequence Control 1 (ADCSSCTL1), offset 0x064**Register 32: ADC Sample Sequence Control 2 (ADCSSCTL2), offset 0x084**

These registers contain the configuration information for each sample for a sequence executed with Sample Sequencer 1 or 2. When configuring a sample sequence, the **END** bit must be set for the final sample, whether it be after the first sample, fourth sample, or any sample in between. These registers are 16-bits wide and contain information for four possible samples. See the **ADCSSCTL0** register on page 1262 for detailed bit descriptions. The **ADCSSCTL1** register configures Sample Sequencer 1 and the **ADCSSCTL2** register configures Sample Sequencer 2.

Register 33: ADC Sample Sequence 1 Operation (ADCSSOP1), offset 0x070**Register 34: ADC Sample Sequence 2 Operation (ADCSSOP2), offset 0x090**

This register determines whether the sample from the given conversion on Sample Sequence n is saved in the Sample Sequence n FIFO or sent to the digital comparator unit. The **ADCSSOP1** register controls Sample Sequencer 1 and the **ADCSSOP2** register controls Sample Sequencer 2.

ADC Sample Sequence n Operation (ADCSSOPn)

Register 35: ADC Sample Sequence 1 Digital Comparator Select (ADCSSDC1), offset 0x074

Register 36: ADC Sample Sequence 2 Digital Comparator Select (ADCSSDC2), offset 0x094

These registers determine which digital comparator receives the sample from the given conversion on Sample Sequence n if the corresponding S_nDCOP bit in the **ADCSSOPn** register is set. The **ADCSSDC1** register controls the selection for Sample Sequencer 1 and the **ADCSSDC2** register controls the selection for Sample Sequencer 2.

Register 37: ADC Sample Sequence Extended Input Multiplexer Select 1 (ADCSEMUX1), offset 0x078

Register 38: ADC Sample Sequence Extended Input Multiplexer Select 2 (ADCSEMUX2), offset 0x098

This register, along with the **ADCSSMUX1** or **ADCSSMUX2** register, defines the analog input configuration for each sample in a sequence executed with either Sample Sequencer 1 or 2. If a bit in this register is set, the corresponding **MUX_n** field in the **ADCSSMUX1** or **ADCSSMUX2** register selects from **AIN[23:16]**. When a bit in this register is clear, the corresponding **MUX_n** field selects from **AIN[15:0]**. This register is 16 bits wide and contains information for four possible samples. The **ADCSEMUX1** register controls Sample Sequencer 1 and the **ADCSEMUX2** register controls Sample Sequencer 2.

Note that this register is not used when the differential channel designation is used (the **D_n** bit is set in the **ADCSSCTL1** or **ADCSSCTL2** register) because the **ADCSSMUX1** or **ADCSSMUX2** register can select all the available pairs.

|-----------|----------|------|--------|---|
| 31:13 | reserved | RO | 0x0000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 12 | EMUX3 | RW | 0x0 | 4th Sample Input Select (Upper Bit) The EMUX3 field is used during the fourth sample of a sequence executed with the sample sequencer. Value Description 0 The fourth sample input is selected from AIN[15:0] using the ADCSSMUX1 or ADCSSMUX2 register. For example, if the MUX3 field is 0x0, AIN0 is selected. 1 The fourth sample input is selected from AIN[23:16] using the ADCSSMUX1 or ADCSSMUX2 register. For example, if the MUX3 field is 0x0, AIN16 is selected. |
| 11:9 | reserved | RO | 0x0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|-------|---|
| 8 | EMUX2 | RW | 0x0 | 3rd Sample Input Select (Upper Bit) The EMUX2 field is used during the third sample of a sequence executed with the sample sequencer. This bit has the same description as EMUX3. |
| 7:5 | reserved | RO | 0x0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 4 | EMUX1 | RW | 0x0 | 2th Sample Input Select (Upper Bit) The EMUX1 field is used during the second sample of a sequence executed with the sample sequencer. This bit has the same description as EMUX3. |
| 3:1 | reserved | RO | 0x0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 0 | EMUX0 | RW | 0x0 | 1st Sample Input Select (Upper Bit) The EMUX0 field is used during the first sample of a sequence executed with the sample sequencer. This bit has the same description as EMUX3. |

Register 39: ADC Sample Sequence 1 Sample and Hold Time (ADCSSTSH1), offset 0x07C

Register 40: ADC Sample Sequence 2 Sample and Hold Time (ADCSSTSH2), offset 0x09C

These registers control the sample period size for each sample step of sequencer 1 and sequencer 2. Each sample and hold period select specifies the time allocated to the sample and hold circuit as shown by the encodings in Table 18-3 on page 1209.

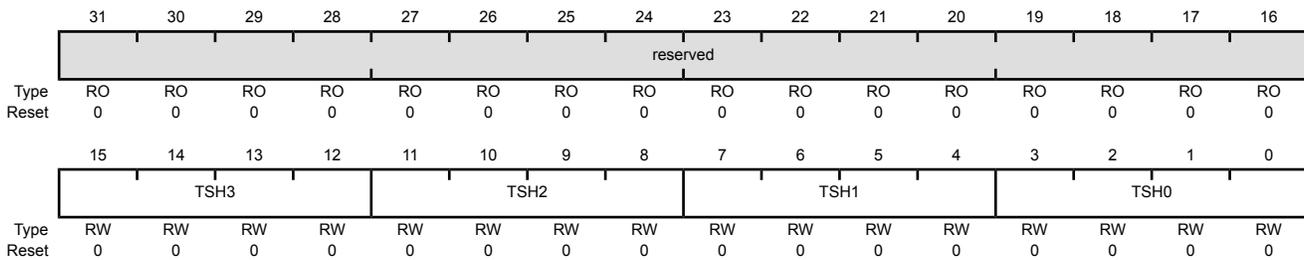

Note: If sampling the internal temperature sensor, the sample and hold width should be at least 16 ADC clocks ($T_{SHn} = 0x4$).

Table 18-9. Sample and Hold Width in ADC Clocks

| TSHn Encoding | N _{SH} |

Register 41: ADC Sample Sequence Input Multiplexer Select 3 (ADCSSMUX3), offset 0x0A0

This register, along with the **ADCSEMUX3** register, defines the analog input configuration for the sample in a sequence executed with Sample Sequencer 3. If the **EMUX0** bit in the **ADCSEMUX3** register is set, the **MUX0** field in this register selects from **AIN[23:16]**. When the **EMUX0** bit is clear, the **MUX0** field selects from **AIN[15:0]**. This register is four bits wide and contains information for one possible sample. See the **ADCSSMUX0** register on page 1260 for detailed bit descriptions.

ADC Sample Sequence Input Multiplexer Select 3 (ADCSSMUX3)

| 3:0 | MUX0 | RW | 0 | 1st Sample Input Select |

Register 42: ADC Sample Sequence Control 3 (ADCSSCTL3), offset 0x0A4

This register contains the configuration information for a sample executed with Sample Sequencer 3. This register is 4 bits wide and contains information for one possible sample. See the **ADCSSCTL0** register on page 1262 for detailed bit descriptions.

Note: When configuring a sample sequence in this register, the **END0** bit must be set.

ADC Sample Sequence Control 3 (ADCSSCTL3)

| 0 | S0DCOP | RW | 0 | Sample 0 Digital Comparator Operation |

Value Description

| | |
|---|--|
| 0 | The sample is saved in Sample Sequence FIFO3. |
| 1 | The sample is sent to the digital comparator unit specified by the S0DCSEL bit in the ADCSSDC03 register, and the value is not written to the FIFO. |

Register 44: ADC Sample Sequence 3 Digital Comparator Select (ADCSSDC3), offset 0x0B4

This register determines which digital comparator receives the sample from the given conversion on Sample Sequence 3 if the corresponding S_nDCOP bit in the **ADCSSOP3** register is set.

ADC Sample Sequence 3 Digital Comparator Select (ADCSSDC3)

ADC0 base: 0x4003.8000

| 0x6 | Digital Comparator Unit 6 (ADCDCOMP6 and ADCCCTL6) |
| 0x7 | Digital Comparator Unit 7 (ADCDCOMP7 and ADCCCTL7) |

Register 45: ADC Sample Sequence Extended Input Multiplexer Select 3 (ADCSEMUX3), offset 0x0B8

This register, along with the **ADCSSMUX3** register, defines the analog input configuration for the sample in a sequence executed with Sample Sequencer 3. If **EMUX0** is set, the **MUX0** field in the **ADCSSMUX3** register selects from **AIN[23:16]**. When **EMUX0** is clear, the **MUX0** field selects from **AIN[15:0]**. This register is 1 bit wide and contains information for one possible sample.

Note that this register is not used when the differential channel designation is used (the **Dn** bit is set in the **ADCSSCTL3** register) because the **ADCSSMUX3** register can select all the available pairs.

ADC Sample Sequence Extended Input Multiplexer Select 3 (ADCSEMUX3)

For example, if the MUX0 field is 0x0, AIN0 is selected.</p> <p>1 The sample input is selected from AIN[23:16] using the ADCSSMUX3 register. For example, if the MUX0 field is 0x0, AIN16 is selected.</p> |

Register 46: ADC Sample Sequence 3 Sample and Hold Time (ADCSSTSH3), offset 0x0BC

This register controls the sample period size for the sample in sequencer 3. The sample and hold period select specifies the time allocated to the sample and hold circuit as shown by the encodings in Table 18-3 on page 1209

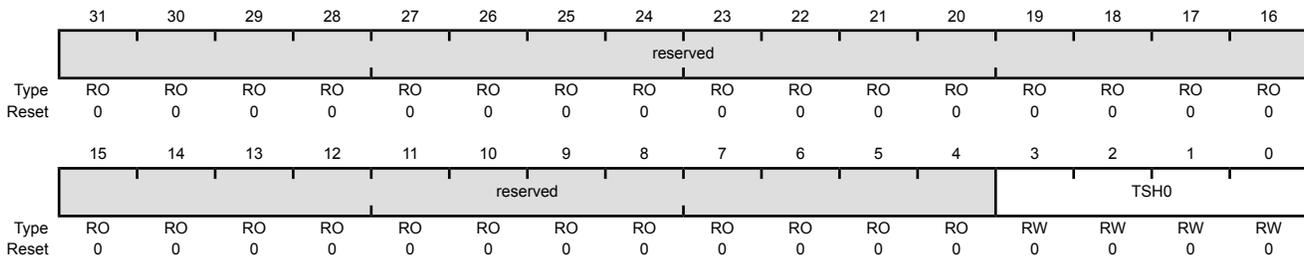

Note: If sampling the internal temperature sensor, the sample and hold width should be at least 16 ADC clocks ($T_{SHn} = 0x4$).

Table 18-10. Sample and Hold Width in ADC Clocks

Register 47: ADC Digital Comparator Reset Initial Conditions (ADCDCRIC), offset 0xD00

This register provides the ability to reset any of the digital comparator interrupt or trigger functions back to their initial conditions. Resetting these functions ensures that the data that is being used by the interrupt and trigger functions in the digital comparator unit is not stale.

ADC Digital Comparator Reset Initial Conditions (ADCDCRIC)

ADC0 base: 0x4003.8000
 ADC1 base: 0x4003.9000
 Offset 0xD00
 Type WO, reset 0x0000.0000

19 Universal Asynchronous Receivers/Transmitters (UARTs)

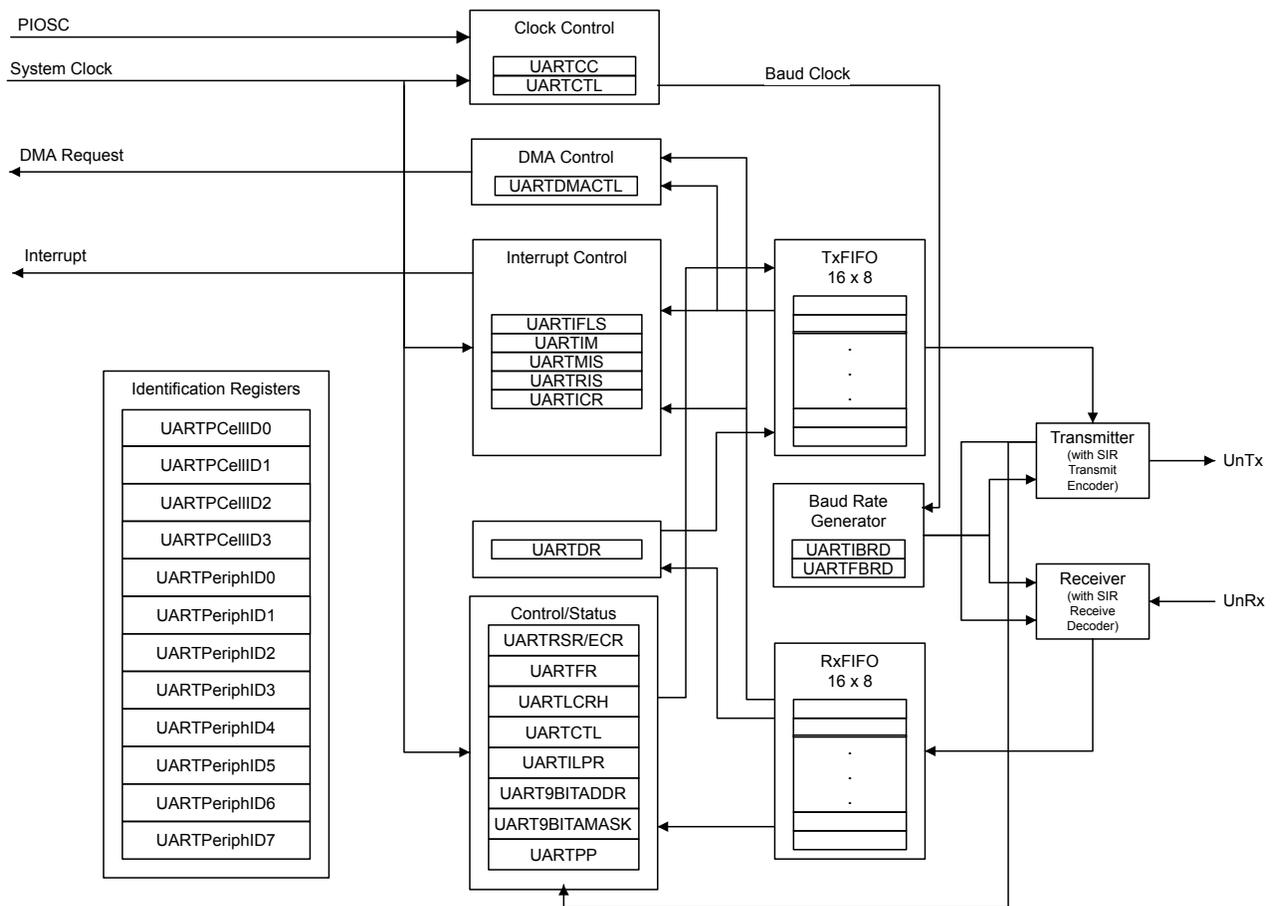

The TM4C129XKCZAD controller includes eight Universal Asynchronous Receiver/Transmitter (UART) with the following features:

- Programmable baud-rate generator allowing speeds up to 7.5 Mbps for regular speed (divide by 16) and 15 Mbps for high speed (divide by 8)
- Separate 16x8 transmit (TX) and receive (RX) FIFOs to reduce CPU interrupt service loading
- Programmable FIFO length, including 1-byte deep operation providing conventional double-buffered interface
- FIFO trigger levels of 1/8, 1/4, 1/2, 3/4, and 7/8
- Standard asynchronous communication bits for start, stop, and parity
- Line-break generation and detection
- Fully programmable serial interface characteristics
 - 5, 6, 7, or 8 data bits
 - Even, odd, stick, or no-parity bit generation/detection
 - 1 or 2 stop bit generation
- IrDA serial-IR (SIR) encoder/decoder providing
 - Programmable use of IrDA Serial Infrared (SIR) or UART input/output
 - Support of IrDA SIR encoder/decoder functions for data rates up to 115.2 Kbps half-duplex
 - Support of normal 3/16 and low-power (1.41-2.23 μ s) bit durations
 - Programmable internal clock generator enabling division of reference clock by 1 to 256 for low-power mode bit duration
- Support for communication with ISO 7816 smart cards
- Modem functionality available on the following UARTs:
 - UART0 (modem flow control and modem status)
 - UART1 (modem flow control and modem status)
 - UART2 (modem flow control)
 - UART3 (modem flow control)
 - UART4 (modem flow control)
- EIA-485 9-bit support

- Standard FIFO-level and End-of-Transmission interrupts
- Efficient transfers using Micro Direct Memory Access Controller (μ DMA)
 - Separate channels for transmit and receive
 - Receive single request asserted when data is in the FIFO; burst request asserted at programmed FIFO level
 - Transmit single request asserted when there is space in the FIFO; burst request asserted at programmed FIFO level
- Global Alternate Clock (ALTCLK) resource or System Clock (SYSCLK) can be used to generate baud clock

19.1 Block Diagram

Figure 19-1. UART Module Block Diagram

19.2 Signal Description

The following table lists the external signals of the UART module and describes the function of each. The UART signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin

placements for these UART signals. The `AFSEL` bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 803) should be set to choose the UART function. The number in parentheses is the encoding that must be programmed into the `PMCn` field in the **GPIO Port Control (GPIOPTCL)** register (page 820) to assign the UART signal to the specified GPIO port pin. For more information on configuring GPIOs, see “General-Purpose Input/Outputs (GPIOs)” on page 772.

19.3 Functional Description

Each TM4C129XKCZAD UART performs the functions of parallel-to-serial and serial-to-parallel conversions. It is similar in functionality to a 16C550 UART, but is not register compatible.

The UART is configured for transmit and/or receive via the TXE and RXE bits of the **UART Control (UARTCTL)** register (see page 1340). Transmit and receive are both enabled out of reset. Before any

control registers are programmed, the UART must be disabled by clearing the `UARTEN` bit in `UARTCTL`. If the UART is disabled during a TX or RX operation, the current transaction is completed prior to the UART stopping.

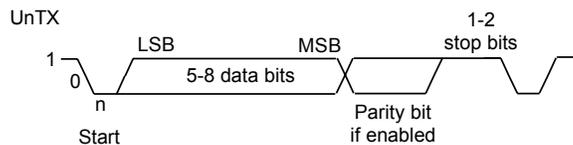

The UART module also includes a serial IR (SIR) encoder/decoder block that can be connected to an infrared transceiver to implement an IrDA SIR physical layer. The SIR function is programmed using the `UARTCTL` register.

19.3.1 Transmit/Receive Logic

The transmit logic performs parallel-to-serial conversion on the data read from the transmit FIFO. The control logic outputs the serial bit stream beginning with a start bit and followed by the data bits (LSB first), parity bit, and the stop bits according to the programmed configuration in the control registers. See Figure 19-2 on page 1316 for details.

The receive logic performs serial-to-parallel conversion on the received bit stream after a valid start pulse has been detected. Overrun, parity, frame error checking, and line-break detection are also performed, and their status accompanies the data that is written to the receive FIFO.

Figure 19-2. UART Character Frame

19.3.2 Baud-Rate Generation

The baud-rate divisor is a 22-bit number consisting of a 16-bit integer and a 6-bit fractional part. The number formed by these two values is used by the baud-rate generator to determine the bit period. Having a fractional baud-rate divisor allows the UART to generate all the standard baud rates.

The 16-bit integer is loaded through the **UART Integer Baud-Rate Divisor (UARTIBRD)** register (see page 1336) and the 6-bit fractional part is loaded with the **UART Fractional Baud-Rate Divisor (UARTFBRD)** register (see page 1337). The baud-rate divisor (BRD) has the following relationship to the system clock (where *BRDI* is the integer part of the BRD and *BRDF* is the fractional part, separated by a decimal place.)

$$BRD = BRDI + BRDF = \text{UARTSysClk} / (\text{ClkDiv} * \text{Baud Rate})$$

where `UARTSysClk` is the system clock connected to the UART, and `ClkDiv` is either 16 (if `HSE` in `UARTCTL` is clear) or 8 (if `HSE` is set). By default, this will be the main system clock described in “Clock Control” on page 241. Alternatively, the UART may be clocked from the internal precision oscillator (PIOSC), independent of the system clock selection. This will allow the UART clock to be programmed independently of the system clock PLL settings. See the `UARTCC` register for more details.

The 6-bit fractional number (that is to be loaded into the `DIVFRAC` bit field in the `UARTFBRD` register) can be calculated by taking the fractional part of the baud-rate divisor, multiplying it by 64, and adding 0.5 to account for rounding errors:

$$\text{UARTFBRD}[\text{DIVFRAC}] = \text{integer}(\text{BRDF} * 64 + 0.5)$$

The UART generates an internal baud-rate reference clock at 8x or 16x the baud-rate (referred to as `Baud8` and `Baud16`, depending on the setting of the `HSE` bit (bit 5) in `UARTCTL`). This reference clock is divided by 8 or 16 to generate the transmit clock, and is used for error detection during

receive operations. Note that the state of the `HSE` bit has no effect on clock generation in ISO 7816 smart card mode (when the `SMART` bit in the `UARTCTL` register is set).

Along with the **UART Line Control, High Byte (UARTLCRH)** register (see page 1338), the `UARTIBRD` and `UARTFBRD` registers form an internal 30-bit register. This internal register is only updated when a write operation to `UARTLCRH` is performed, so any changes to the baud-rate divisor must be followed by a write to the `UARTLCRH` register for the changes to take effect.

To update the baud-rate registers, there are four possible sequences:

- `UARTIBRD` write, `UARTFBRD` write, and `UARTLCRH` write
- `UARTFBRD` write, `UARTIBRD` write, and `UARTLCRH` write
- `UARTIBRD` write and `UARTLCRH` write
- `UARTFBRD` write and `UARTLCRH` write

19.3.3 Data Transmission

Data received or transmitted is stored in two 16-byte FIFOs, though the receive FIFO has an extra four bits per character for status information. For transmission, data is written into the transmit FIFO. If the UART is enabled, it causes a data frame to start transmitting with the parameters indicated in the `UARTLCRH` register. Data continues to be transmitted until there is no data left in the transmit FIFO. The `BUSY` bit in the **UART Flag (UARTFR)** register (see page 1332) is asserted as soon as data is written to the transmit FIFO (that is, if the FIFO is non-empty) and remains asserted while data is being transmitted. The `BUSY` bit is negated only when the transmit FIFO is empty, and the last character has been transmitted from the shift register, including the stop bits. The UART can indicate that it is busy even though the UART may no longer be enabled.

When the receiver is idle (the `UnRx` signal is continuously 1), and the data input goes Low (a start bit has been received), the receive counter begins running and data is sampled on the eighth cycle of `Baud16` or fourth cycle of `Baud8` depending on the setting of the `HSE` bit (bit 5) in `UARTCTL` (described in “Transmit/Receive Logic” on page 1316).

The start bit is valid and recognized if the `UnRx` signal is still low on the eighth cycle of `Baud16` (`HSE` clear) or the fourth cycle of `Baud 8` (`HSE` set), otherwise it is ignored. After a valid start bit is detected, successive data bits are sampled on every 16th cycle of `Baud16` or 8th cycle of `Baud8` (that is, one bit period later) according to the programmed length of the data characters and value of the `HSE` bit in `UARTCTL`. The parity bit is then checked if parity mode is enabled. Data length and parity are defined in the `UARTLCRH` register.

Lastly, a valid stop bit is confirmed if the `UnRx` signal is High, otherwise a framing error has occurred. When a full word is received, the data is stored in the receive FIFO along with any error bits associated with that word.

19.3.4 Serial IR (SIR)

The UART peripheral includes an IrDA serial-IR (SIR) encoder/decoder block. The IrDA SIR block provides functionality that converts between an asynchronous UART data stream and a half-duplex serial SIR interface. No analog processing is performed on-chip. The role of the SIR block is to provide a digital encoded output and decoded input to the UART. When enabled, the SIR block uses the `UnTx` and `UnRx` pins for the SIR protocol. These signals should be connected to an infrared transceiver to implement an IrDA SIR physical layer link. The SIR block can receive and transmit, but it is only half-duplex so it cannot do both at the same time. Transmission must be stopped before

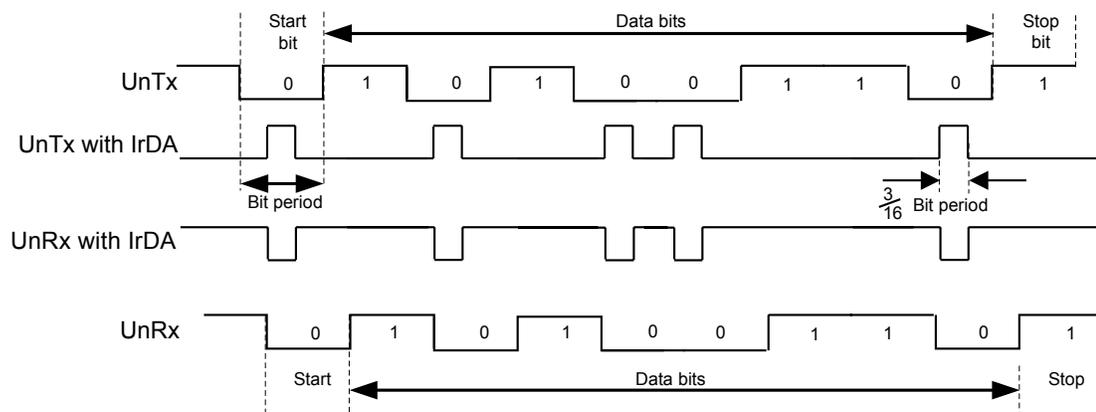

data can be received. The IrDA SIR physical layer specifies a minimum 10-ms delay between transmission and reception. The SIR block has two modes of operation:

- In normal IrDA mode, a zero logic level is transmitted as a high pulse of $\frac{3}{16}$ th duration of the selected baud rate bit period on the output pin, while logic one levels are transmitted as a static LOW signal. These levels control the driver of an infrared transmitter, sending a pulse of light for each zero. On the reception side, the incoming light pulses energize the photo transistor base of the receiver, pulling its output LOW and driving the UART input pin LOW.
- In low-power IrDA mode, the width of the transmitted infrared pulse is set to three times the period of the internally generated IrLPBaud16 signal (1.63 μ s, assuming a nominal 1.8432 MHz frequency) by changing the appropriate bit in the **UARTCTL** register (see page 1340).

Whether the device is in normal or low-power IrDA mode, a start bit is deemed valid if the decoder is still Low, one period of IrLPBaud16 after the Low was first detected. This enables a normal-mode UART to receive data from a low-power mode UART that can transmit pulses as small as 1.41 μ s. Thus, for both low-power and normal mode operation, the **ILPDVSR** field in the **UARTILPR** register must be programmed such that $1.42 \text{ MHz} < F_{\text{IrLPBaud16}} < 2.12 \text{ MHz}$, resulting in a low-power pulse duration of 1.41–2.11 μ s (three times the period of IrLPBaud16). The minimum frequency of IrLPBaud16 ensures that pulses less than one period of IrLPBaud16 are rejected, but pulses greater than 1.4 μ s are accepted as valid pulses.

Figure 19-3 on page 1318 shows the UART transmit and receive signals, with and without IrDA modulation.

Figure 19-3. IrDA Data Modulation

In both normal and low-power IrDA modes:

- During transmission, the UART data bit is used as the base for encoding
- During reception, the decoded bits are transferred to the UART receive logic

The IrDA SIR physical layer specifies a half-duplex communication link, with a minimum 10-ms delay between transmission and reception. This delay must be generated by software because it is not automatically supported by the UART. The delay is required because the infrared receiver electronics might become biased or even saturated from the optical power coupled from the adjacent transmitter LED. This delay is known as latency or receiver setup time.

19.3.5 ISO 7816 Support

The UART offers basic support to allow communication with an ISO 7816 smartcard. When bit 3 (*SMART*) of the **UARTCTL** register is set, the *UnTx* signal is used as a bit clock, and the *UnRx* signal is used as the half-duplex communication line connected to the smartcard. A GPIO signal can be used to generate the reset signal to the smartcard. The remaining smartcard signals should be provided by the system design. The maximum clock rate in this mode is system clock / 16.

When using ISO 7816 mode, the **UARTLCRH** register must be set to transmit 8-bit words (*WLEN* bits 6:5 configured to 0x3) with EVEN parity (*PEN* set and *EPS* set). In this mode, the UART automatically uses 2 stop bits, and the *STP2* bit of the **UARTLCRH** register is ignored.

If a parity error is detected during transmission, *UnRx* is pulled Low during the second stop bit. In this case, the UART aborts the transmission, flushes the transmit FIFO and discards any data it contains, and raises a parity error interrupt, allowing software to detect the problem and initiate retransmission of the affected data. Note that the UART does not support automatic retransmission in this case.

19.3.6 Modem Handshake Support

This section describes how to configure and use the modem flow control and status signals for a UART when connected as a DTE (data terminal equipment) or as a DCE (data communications equipment). In general, a modem is a DCE and a computing device that connects to a modem is the DTE.

19.3.6.1 Signaling

The status signals provided by a UART differ based on whether the UART is used as a DTE or DCE. When used as a DTE, the modem flow control and status signals are defined as:

- $\overline{\text{UnCTS}}$ is Clear To Send
- $\overline{\text{UnDSR}}$ is Data Set Ready
- $\overline{\text{UnDCD}}$ is Data Carrier Detect
- $\overline{\text{UnRI}}$ is Ring Indicator
- $\overline{\text{UnRTS}}$ is Request To Send
- $\overline{\text{UnDTR}}$ is Data Terminal Ready

When used as a DCE, the modem flow control and status signals are defined as:

- $\overline{\text{UnCTS}}$ is Request To Send
- $\overline{\text{UnDSR}}$ is Data Terminal Ready
- $\overline{\text{UnRTS}}$ is Clear To Send
- $\overline{\text{UnDTR}}$ is Data Set Ready

Note that the support for DCE functions Data Carrier Detect and Ring Indicator are not provided. If these signals are required, their function can be emulated by using a general-purpose I/O signal and providing software support.

19.3.6.2 Flow Control

Flow control can be accomplished by either hardware or software. The following sections describe the different methods.

Hardware Flow Control (RTS/CTS)

Hardware flow control between two devices is accomplished by connecting the $\overline{\text{UnRTS}}$ output to the Clear-To-Send input on the receiving device, and connecting the Request-To-Send output on the receiving device to the $\overline{\text{UnCTS}}$ input.

The $\overline{\text{UnCTS}}$ input controls the transmitter. The transmitter may only transmit data when the $\overline{\text{UnCTS}}$ input is asserted. The $\overline{\text{UnRTS}}$ output signal indicates the state of the receive FIFO. $\overline{\text{UnCTS}}$ remains asserted until the preprogrammed watermark level is reached, indicating that the Receive FIFO has no space to store additional characters.

The **UARTCTL** register bits 15 (CTSEN) and 14 (RTSEN) specify the flow control mode as shown in Table 19-2 on page 1320.

Table 19-2. Flow Control Mode

| CTSEN | RTSEN | Description |
|-------|-------|--|
| 1 | 1 | RTS and CTS flow control enabled |
| 1 | 0 | Only CTS flow control enabled |
| 0 | 1 | Only RTS flow control enabled |
| 0 | 0 | Both RTS and CTS flow control disabled |

Note that when RTSEN is 1, software cannot modify the $\overline{\text{UnRTS}}$ output value through the **UARTCTL** register Request to Send (RTS) bit, and the status of the RTS bit should be ignored.

Software Flow Control (Modem Status Interrupts)

Software flow control between two devices is accomplished by using interrupts to indicate the status of the UART. Interrupts may be generated for the $\overline{\text{UnDSR}}$, $\overline{\text{UnDCD}}$, $\overline{\text{UnCTS}}$, and $\overline{\text{UnRI}}$ signals using bits 3:0 of the **UARTIM** register, respectively. The raw and masked interrupt status may be checked using the **UARTRIS** and **UARTMIS** register. These interrupts may be cleared using the **UARTICR** register.

19.3.7 9-Bit UART Mode

The UART provides a 9-bit mode that is enabled with the 9BITEN bit in the **UART9BITADDR** register. This feature is useful in a multi-drop configuration of the UART where a single master connected to multiple slaves can communicate with a particular slave through its address or set of addresses along with a qualifier for an address byte. All the slaves check for the address qualifier in the place of the parity bit and, if set, then compare the byte received with the preprogrammed address. If the address matches, then it receives or sends further data. If the address does not match, it drops the address byte and any subsequent data bytes. If the UART is in 9-bit mode, then the receiver operates with no parity mode. The address can be predefined to match with the received byte and it can be configured with the **UART9BITADDR** register. The matching can be extended to a set of addresses using the address mask in the **UART9BITAMASK** register. By default, the **UART9BITAMASK** is 0xFF, meaning that only the specified address is matched.

When not finding a match, the rest of the data bytes with the 9th bit cleared are dropped. If a match is found, then an interrupt is generated to the NVIC for further action. The subsequent data bytes with the cleared 9th bit are stored in the FIFO. Software can mask this interrupt in case μ DMA and/or FIFO operations are enabled for this instance and processor intervention is not required. All the

send transactions with 9-bit mode are data bytes and the 9th bit is cleared. Software can override the 9th bit to be set (to indicate address) by overriding the parity settings to sticky parity with odd parity enabled for a particular byte. To match the transmission time with correct parity settings, the address byte can be transmitted as a single then a burst transfer. The Transmit FIFO does not hold the address/data bit, hence software should take care of enabling the address bit appropriately.

19.3.8 FIFO Operation

The UART has two 16x8 FIFOs; one for transmit and one for receive. Both FIFOs are accessed via the **UART Data (UARTDR)** register (see page 1327). Read operations of the **UARTDR** register return a 12-bit value consisting of 8 data bits and 4 error flags while write operations place 8-bit data in the transmit FIFO.

Out of reset, both FIFOs are disabled and act as 1-byte-deep holding registers. The FIFOs are enabled by setting the **FEN** bit in **UARTLCRH** (page 1338).

FIFO status can be monitored via the **UART Flag (UARTFR)** register (see page 1332) and the **UART Receive Status (UARTSR)** register. Hardware monitors empty, full and overrun conditions. The **UARTFR** register contains empty and full flags (**TXFE**, **TXFF**, **RXFE**, and **RXFF** bits), and the **UARTSR** register shows overrun status via the **OE** bit. If the FIFOs are disabled, the empty and full flags are set according to the status of the 1-byte-deep holding registers.

The trigger points at which the FIFOs generate interrupts is controlled via the **UART Interrupt FIFO Level Select (UARTIFLS)** register (see page 1344). Both FIFOs can be individually configured to trigger interrupts at different levels. Available configurations include $\frac{1}{8}$, $\frac{1}{4}$, $\frac{1}{2}$, $\frac{3}{4}$, and $\frac{7}{8}$. For example, if the $\frac{1}{4}$ option is selected for the receive FIFO, the UART generates a receive interrupt after 4 data bytes are received. Out of reset, both FIFOs are configured to trigger an interrupt at the $\frac{1}{2}$ mark.

19.3.9 Interrupts

The UART can generate interrupts when the following conditions are observed:

- Overrun Error
- Break Error
- Parity Error
- Framing Error
- Receive Timeout
- Transmit (when condition defined in the **TXIFLSEL** bit in the **UARTIFLS** register is met, or if the **EOT** bit in **UARTCTL** is set, when the last bit of all transmitted data leaves the serializer)
- Receive (when condition defined in the **RXIFLSEL** bit in the **UARTIFLS** register is met)

All of the interrupt events are ORed together before being sent to the interrupt controller, so the UART can only generate a single interrupt request to the controller at any given time. Software can service multiple interrupt events in a single interrupt service routine by reading the **UART Masked Interrupt Status (UARTMIS)** register (see page 1354).

The interrupt events that can trigger a controller-level interrupt are defined in the **UART Interrupt Mask (UARTIM)** register (see page 1346) by setting the corresponding **IM** bits. If interrupts are not used, the raw interrupt status is visible via the **UART Raw Interrupt Status (UARTRIS)** register (see page 1350).

Note: For receive timeout, the `RTIM` bit in the **UARTIM** register must be set to see the `RTMIS` and `RTRIS` status in the **UARTMIS** and **UARTRIS** registers.

Interrupts are always cleared (for both the **UARTMIS** and **UARTRIS** registers) by writing a 1 to the corresponding bit in the **UART Interrupt Clear (UARTICR)** register (see page 1358).

The receive timeout interrupt is asserted when the receive FIFO is not empty, and no further data is received over a 32-bit period when the `HSE` bit is clear or over a 64-bit period when the `HSE` bit is set. The receive timeout interrupt is cleared either when the FIFO becomes empty through reading all the data (or by reading the holding register), or when a 1 is written to the corresponding bit in the **UARTICR** register.

The receive interrupt changes state when one of the following events occurs:

- If the FIFOs are enabled and the receive FIFO reaches the programmed trigger level, the `RXRIS` bit is set. The receive interrupt is cleared by reading data from the receive FIFO until it becomes less than the trigger level, or by clearing the interrupt by writing a 1 to the `RXIC` bit.
- If the FIFOs are disabled (have a depth of one location) and data is received thereby filling the location, the `RXRIS` bit is set. The receive interrupt is cleared by performing a single read of the receive FIFO, or by clearing the interrupt by writing a 1 to the `RXIC` bit.

The transmit interrupt changes state when one of the following events occurs:

- If the FIFOs are enabled and the transmit FIFO progresses through the programmed trigger level, the `TXRIS` bit is set. The transmit interrupt is based on a transition through level, therefore the FIFO must be written past the programmed trigger level otherwise no further transmit interrupts will be generated. The transmit interrupt is cleared by writing data to the transmit FIFO until it becomes greater than the trigger level, or by clearing the interrupt by writing a 1 to the `TXIC` bit.
- If the FIFOs are disabled (have a depth of one location) and there is no data present in the transmitters single location, the `TXRIS` bit is set. It is cleared by performing a single write to the transmit FIFO, or by clearing the interrupt by writing a 1 to the `TXIC` bit.

19.3.10 Loopback Operation

The UART can be placed into an internal loopback mode for diagnostic or debug work by setting the `LBE` bit in the **UARTCTL** register (see page 1340). In loopback mode, data transmitted on the `UnTx` output is received on the `UnRx` input. Note that the `LBE` bit should be set before the UART is enabled.

19.3.11 DMA Operation

The UART provides an interface to the μ DMA controller with separate channels for transmit and receive. The DMA operation of the UART is enabled through the **UART DMA Control (UARTDMACTL)** register. When DMA operation is enabled, the UART asserts a DMA request on the receive or transmit channel when the associated FIFO can transfer data. For the receive channel, a single transfer request is asserted whenever any data is in the receive FIFO. A burst transfer request is asserted whenever the amount of data in the receive FIFO is at or above the FIFO trigger level configured in the **UARTIFLS** register. For the transmit channel, a single transfer request is asserted whenever there is at least one empty location in the transmit FIFO. The burst request is asserted whenever the transmit FIFO contains fewer characters than the FIFO trigger level. The single and burst DMA transfer requests are handled automatically by the μ DMA controller depending on how the DMA channel is configured.

To enable DMA operation for the receive channel, set the `RXDMAE` bit of the **DMA Control (UARTDMACTL)** register. To enable DMA operation for the transmit channel, set the `TXDMAE` bit of the **UARTDMACTL** register. The UART can also be configured to stop using DMA for the receive channel if a receive error occurs. If the `DMAERR` bit of the **UARTDMACR** register is set and a receive error occurs, the DMA receive requests are automatically disabled. This error condition can be cleared by clearing the appropriate UART error interrupt.

When the μ DMA is finished transferring data to the TX FIFO or from the RX FIFO, a `dma_done` signal is sent to the UART to indicate completion. The `dma_done` status is indicated through the `DMATXRIS` and `DMARXIS` bits of the **UARTRIS** register. An interrupt can be generated from these status bits by setting the `DMATXIM` and/or `DMARXIM` bits in the **UARTIM** register.

Note: The `DMATXRIS` bit can be used to indicate the μ DMA's completion of data transfer to the TX FIFO. To indicate transfer completion from the UART's serializer, the end-of-transmission bit (`EOT` bit) should be enabled in the **UARTCTL** register. An interrupt can be generated on an end-of-transmission completion by setting the `EOTIM` bit of the **UARTIM** register.

See “Micro Direct Memory Access (μ DMA)” on page 708 for more details about programming the μ DMA controller.

19.4 Initialization and Configuration

To enable and initialize the UART, the following steps are necessary:

1. Enable the UART module using the **RCGCUART** register (see page 405).
2. Enable the clock to the appropriate GPIO module via the **RCGCGPIO** register (see page 399). To find out which GPIO port to enable, refer to Table 31-5 on page 2081.
3. Set the GPIO `AFSEL` bits for the appropriate pins (see page 803). To determine which GPIOs to configure, see Table 31-4 on page 2064.
4. Configure the GPIO current level and/or slew rate as specified for the mode selected (see page 805 and page 813).
5. Configure the `PMCn` fields in the **GPIOPCTL** register to assign the UART signals to the appropriate pins (see page 820 and Table 31-5 on page 2081).

To use the UART, the peripheral clock must be enabled by setting the appropriate bit in the **RCGCUART** register (page 405). In addition, the clock to the appropriate GPIO module must be enabled via the **RCGCGPIO** register (page 399) in the System Control module. To find out which GPIO port to enable, refer to Table 31-5 on page 2081.

This section discusses the steps that are required to use a UART module. For this example, the UART clock is assumed to be 20 MHz, and the desired UART configuration is:

- 115200 baud rate
- Data length of 8 bits
- One stop bit
- No parity
- FIFOs disabled

- No interrupts

The first thing to consider when programming the UART is the baud-rate divisor (BRD), because the **UARTIBRD** and **UARTFBRD** registers must be written before the **UARTLCRH** register. Using the equation described in “Baud-Rate Generation” on page 1316, the BRD can be calculated:

$$\text{BRD} = 20,000,000 / (16 * 115,200) = 10.8507$$

which means that the **DIVINT** field of the **UARTIBRD** register (see page 1336) should be set to 10 decimal or 0xA. The value to be loaded into the **UARTFBRD** register (see page 1337) is calculated by the equation:

$$\text{UARTFBRD}[\text{DIVFRAC}] = \text{integer}(0.8507 * 64 + 0.5) = 54$$

With the BRD values in hand, the UART configuration is written to the module in the following order:

1. Disable the UART by clearing the **UARTEN** bit in the **UARTCTL** register.
2. Write the integer portion of the BRD to the **UARTIBRD** register.
3. Write the fractional portion of the BRD to the **UARTFBRD** register.
4. Write the desired serial parameters to the **UARTLCRH** register (in this case, a value of 0x0000.0060).
5. Configure the UART clock source by writing to the **UARTCC** register.
6. Optionally, configure the μ DMA channel (see “Micro Direct Memory Access (μ DMA)” on page 708) and enable the DMA option(s) in the **UARTDMACTL** register.
7. Enable the UART by setting the **UARTEN** bit in the **UARTCTL** register.

19.5 Register Map

Table 19-3 on page 1325 lists the UART registers. The offset listed is a hexadecimal increment to the register's address, relative to that UART's base address:

- UART0: 0x4000.C000
- UART1: 0x4000.D000
- UART2: 0x4000.E000
- UART3: 0x4000.F000
- UART4: 0x4001.0000
- UART5: 0x4001.1000
- UART6: 0x4001.2000
- UART7: 0x4001.3000

The UART module clock must be enabled before the registers can be programmed (see page 405). There must be a delay of 3 system clocks after the UART module clock is enabled before any UART module registers are accessed.

The UART must be disabled (see the **UARTEN** bit in the **UARTCTL** register on page 1340) before any of the control registers are reprogrammed. When the UART is disabled during a TX or RX operation, the current transaction is completed prior to the UART stopping.

Note: Registers that contain bits for modem control or status only apply to the following UARTs:

- UART0 (modem flow control and modem status)

- UART1 (modem flow control and modem status)
- UART2 (modem flow control)
- UART3 (modem flow control)
- UART4 (modem flow control)

Table 19-3. UART Register Map

19.6 Register Descriptions

The remainder of this section lists and describes the UART registers, in numerical order by address offset.

Register 1: UART Data (UARTDR), offset 0x000

Important: This register is read-sensitive. See the register description for details.

This register is the data register (the interface to the FIFOs).

For transmitted data, if the FIFO is enabled, data written to this location is pushed onto the transmit FIFO. If the FIFO is disabled, data is stored in the transmitter holding register (the bottom word of the transmit FIFO). A write to this register initiates a transmission from the UART.

For received data, if the FIFO is enabled, the data byte and the 4-bit status (break, frame, parity, and overrun) is pushed onto the 12-bit wide receive FIFO. If the FIFO is disabled, the data byte and status are stored in the receiving holding register (the bottom word of the receive FIFO). The received data can be retrieved by reading this register.

UART Data (UARTDR)

UART0 base: 0x4000.C000
 UART1 base: 0x4000.D000
 UART2 base: 0x4000.E000
 UART3 base: 0x4000.F000
 UART4 base: 0x4001.0000
 UART5 base: 0x4001.1000
 UART6 base: 0x4001.2000
 UART7 base: 0x4001.3000
 Offset 0x000
 Type RW, reset 0x0000.0000

Register 2: UART Receive Status/Error Clear (UARTRSR/UARTECR), offset 0x004

The **UARTRSR/UARTECR** register is the receive status register/error clear register.

In addition to the **UARTDR** register, receive status can also be read from the **UARTRSR** register. If the status is read from this register, then the status information corresponds to the entry read from **UARTDR** prior to reading **UARTRSR**. The status information for overrun is set immediately when an overrun condition occurs.

The **UARTRSR** register cannot be written.

A write of any value to the **UARTECR** register clears the framing, parity, break, and overrun errors. All the bits are cleared on reset.

| | | | | |
|---|----|----|---|--------------------|
| 3 | OE | RO | 0 | UART Overrun Error |
|---|----|----|---|--------------------|

Value Description

| Value | Description |
|-------|---|
| 0 | No data has been lost due to a FIFO overrun. |
| 1 | New data was received when the FIFO was full, resulting in data loss. |

This bit is cleared by a write to **UARTECR**.

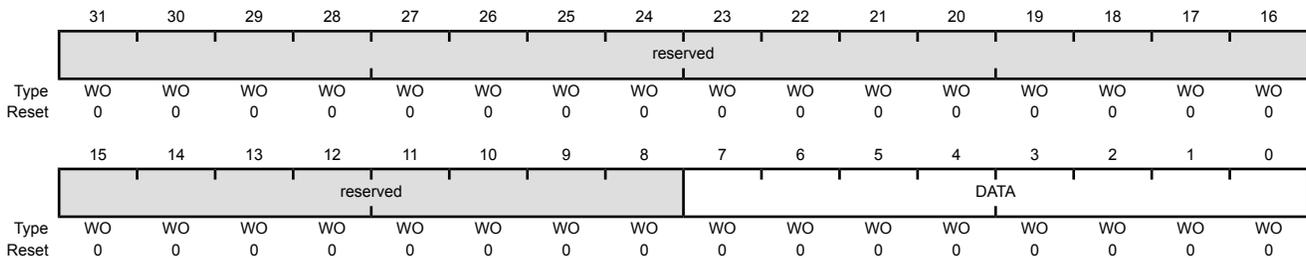

The FIFO contents remain valid because no further data is written when the FIFO is full, only the contents of the shift register are overwritten. The CPU must read the data in order to empty the FIFO.

| 7:0 | DATA | WO | 0x00 | Error Clear A write to this register of any data clears the framing, parity, break, and overrun flags. |

Register 3: UART Flag (UARTFR), offset 0x018

The **UARTFR** register is the flag register. After reset, the **TXFF**, **RXFF**, and **BUSY** bits are 0, and **TXFE** and **RXFE** bits are 1.

Note: Registers that contain bits for modem control or status only apply to the following UARTs:

- UART0 (modem flow control and modem status)
- UART1 (modem flow control and modem status)
- UART2 (modem flow control)
- UART3 (modem flow control)
- UART4 (modem flow control)

| Bit/Field | Name | Type | Reset | Description |
|-----------|------|------|-------|---|
| 3 | BUSY | RO | 0 | UART Busy Value Description 0 The UART is not busy. 1 The UART is busy transmitting data. This bit remains set until the complete byte, including all stop bits, has been sent from the shift register. This bit is set as soon as the transmit FIFO becomes non-empty (regardless of whether UART is enabled). |
| 2 | DCD | RO | 0 | Data Carrier Detect Value Description 0 The UnDCD signal is not asserted. 1 The UnDCD signal is asserted. |
| 1 | DSR | RO | 0 | Data Set Ready Value Description 0 The UnDSR signal is not asserted. 1 The UnDSR signal is asserted. |
| 0 | CTS | RO | 0 | Clear To Send Value Description 0 The UlCTS signal is not asserted. 1 The UnCTS signal is asserted. |

Register 4: UART IrDA Low-Power Register (UARTILPR), offset 0x020

The **UARTILPR** register stores the 8-bit low-power counter divisor value used to derive the low-power SIR pulse width clock by dividing down the system clock (SysClk). All the bits are cleared when reset.

The internal $F_{IrLPBaud16}$ clock is generated by dividing down SysClk according to the low-power divisor value written to **UARTILPR**. The duration of SIR pulses generated when low-power mode is enabled is three times the period of the $F_{IrLPBaud16}$ clock. The low-power divisor value is calculated as follows:

$$ILPDVSR = SysClk / F_{IrLPBaud16}$$

where $F_{IrLPBaud16}$ is nominally 1.8432 MHz.

Because the $F_{IrLPBaud16}$ clock is used to sample transmitted data irrespective of mode, the **ILPDVSR** field must be programmed in both low power and normal mode, such that $1.42 \text{ MHz} < F_{IrLPBaud16} < 2.12 \text{ MHz}$, resulting in a low-power pulse duration of 1.41–2.11 μs (three times the period of $F_{IrLPBaud16}$). The minimum frequency of $F_{IrLPBaud16}$ ensures that pulses less than one period of $F_{IrLPBaud16}$ are rejected, but pulses greater than 1.4 μs are accepted as valid pulses.

Note: Zero is an illegal value. Programming a zero value results in no $F_{IrLPBaud16}$ pulses being generated.

Register 5: UART Integer Baud-Rate Divisor (UARTIBRD), offset 0x024

The **UARTIBRD** register is the integer part of the baud-rate divisor value. All the bits are cleared on reset. The minimum possible divide ratio is 1 (when **UARTIBRD**=0), in which case the **UARTFBRD** register is ignored. When changing the **UARTIBRD** register, the new value does not take effect until transmission/reception of the current character is complete. Any changes to the baud-rate divisor must be followed by a write to the **UARTLCRH** register. See “Baud-Rate Generation” on page 1316 for configuration details.

UART Integer Baud-Rate Divisor (UARTIBRD)

Register 7: UART Line Control (UARTLCRH), offset 0x02C

The **UARTLCRH** register is the line control register. Serial parameters such as data length, parity, and stop bit selection are implemented in this register.

When updating the baud-rate divisor (**UARTIBRD** and/or **UARTIFRD**), the **UARTLCRH** register must also be written. The write strobe for the baud-rate divisor registers is tied to the **UARTLCRH** register.

For the proper execution of the break command, software must set this bit for at least two frames (character periods).</p> |

Register 8: UART Control (UARTCTL), offset 0x030

The **UARTCTL** register is the control register. All the bits are cleared on reset except for the Transmit Enable (TXE) and Receive Enable (RXE) bits, which are set.

To enable the UART module, the **UARTEN** bit must be set. If software requires a configuration change in the module, the **UARTEN** bit must be cleared before the configuration changes are written. If the UART is disabled during a transmit or receive operation, the current transaction is completed prior to the UART stopping.

Note: Registers that contain bits for modem control or status only apply to the following UARTs:

- UART0 (modem flow control and modem status)
- UART1 (modem flow control and modem status)
- UART2 (modem flow control)
- UART3 (modem flow control)
- UART4 (modem flow control)

Note: The **UARTCTL** register should not be changed while the UART is enabled or else the results are unpredictable. The following sequence is recommended for making changes to the **UARTCTL** register.

1. Disable the UART.
2. Wait for the end of transmission or reception of the current character.
3. Flush the transmit FIFO by clearing bit 4 (FEN) in the line control register (**UARTLCRH**).
4. Reprogram the control register.
5. Enable the UART.

Register 9: UART Interrupt FIFO Level Select (UARTIFLS), offset 0x034

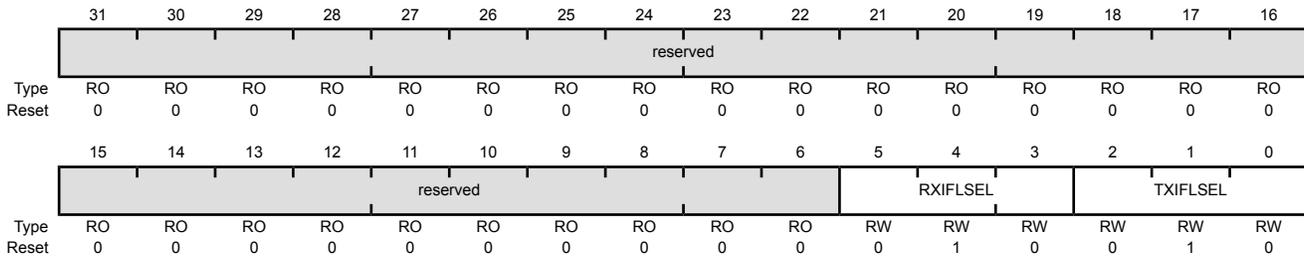

The **UARTIFLS** register is the interrupt FIFO level select register. You can use this register to define the FIFO level at which the **TXRIS** and **RXRIS** bits in the **UARTRIS** register are triggered.

The interrupts are generated based on a transition through a level rather than being based on the level. That is, the interrupts are generated when the fill level progresses through the trigger level. For example, if the receive trigger level is set to the half-way mark, the interrupt is triggered as the module is receiving the 9th character.

Out of reset, the **TXIFLSEL** and **RXIFLSEL** bits are configured so that the FIFOs trigger an interrupt at the half-way mark.

UART Interrupt FIFO Level Select (UARTIFLS)

| 2:0 | TXIFLSEL | RW | 0x2 | UART Transmit Interrupt FIFO Level Select The trigger points for the transmit interrupt are as follows: Value Description 0x0 TX FIFO \leq $\frac{7}{8}$ empty 0x1 TX FIFO \leq $\frac{3}{4}$ empty 0x2 TX FIFO \leq $\frac{1}{2}$ empty (default) 0x3 TX FIFO \leq $\frac{1}{4}$ empty 0x4 TX FIFO \leq $\frac{1}{8}$ empty 0x5-0x7 Reserved Note: If the EOT bit in UARTCTL is set (see page 1340), the transmit interrupt is generated once the FIFO is completely empty and all data including stop bits have left the transmit serializer. In this case, the setting of TXIFLSEL is ignored. |

Register 10: UART Interrupt Mask (UARTIM), offset 0x038

The **UARTIM** register is the interrupt mask set/clear register.

On a read, this register gives the current value of the mask on the relevant interrupt. Setting a bit allows the corresponding raw interrupt signal to be routed to the interrupt controller. Clearing a bit prevents the raw interrupt signal from being sent to the interrupt controller.

Note: Registers that contain bits for modem control or status only apply to the following UARTs:

- UART0 (modem flow control and modem status)
- UART1 (modem flow control and modem status)
- UART2 (modem flow control)
- UART3 (modem flow control)
- UART4 (modem flow control)

| 1 | CTSMIS | RO | 0 | UART Clear to Send Modem Masked Interrupt Status Value Description 0 An interrupt has not occurred or is masked. 1 An unmasked interrupt was signaled due to Clear to Send. This bit is cleared by writing a 1 to the <code>CTSIC</code> bit in the UARTICR register. |
| 0 | RIMIS | RO | 0 | UART Ring Indicator Modem Masked Interrupt Status Value Description 0 An interrupt has not occurred or is masked. 1 An unmasked interrupt was signaled due to Ring Indicator. This bit is cleared by writing a 1 to the <code>RIIC</code> bit in the UARTICR register. |

Register 13: UART Interrupt Clear (UARTICR), offset 0x044

The **UARTICR** register is the interrupt clear register. On a write of 1, the corresponding interrupt (both raw interrupt and masked interrupt, if enabled) is cleared. A write of 0 has no effect.

Note that bits [3:0] are only implemented on UART1. These bits are reserved on UART0 and UART2.

UART Interrupt Clear (UARTICR)

| 0 | RIMIC | W1C | 0 | UART Ring Indicator Modem Interrupt Clear Writing a 1 to this bit clears the RIRIS bit in the UARTRIS register and the RIMIS bit in the UARTMIS register. |

Register 14: UART DMA Control (UARTDMACTL), offset 0x048

The **UARTDMACTL** register is the DMA control register.

UART DMA Control (UARTDMACTL)

UART0 base: 0x4000.C000
 UART1 base: 0x4000.D000
 UART2 base: 0x4000.E000
 UART3 base: 0x4000.F000
 UART4 base: 0x4001.0000
 UART5 base: 0x4001.1000
 UART6 base: 0x4001.2000
 UART7 base: 0x4001.3000
 Offset 0x048
 Type RW, reset 0x0000.0000

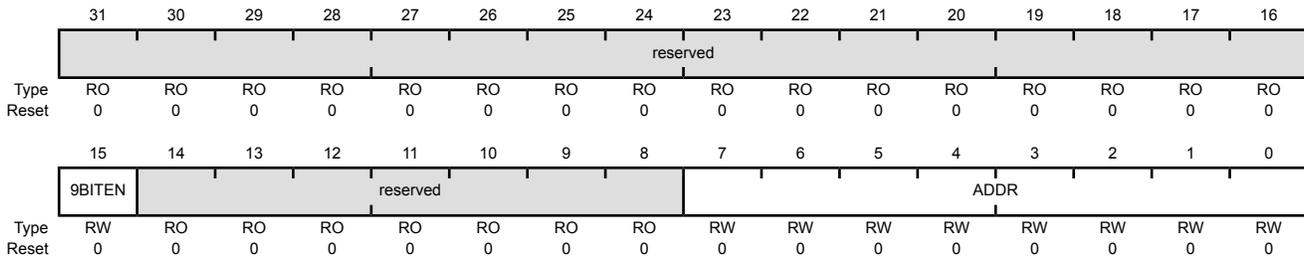

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|-------------|---|
| 31:3 | reserved | RO | 0x00000.000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 2 | DMAERR | RW | 0 | DMA on Error Value Description 0 μDMA receive requests are unaffected when a receive error occurs. 1 μDMA receive requests are automatically disabled when a receive error occurs. |
| 1 | TXDMAE | RW | 0 | Transmit DMA Enable Value Description 0 μDMA for the transmit FIFO is disabled. 1 μDMA for the transmit FIFO is enabled. |
| 0 | RXDMAE | RW | 0 | Receive DMA Enable Value Description 0 μDMA for the receive FIFO is disabled. 1 μDMA for the receive FIFO is enabled. |

Register 15: UART 9-Bit Self Address (UART9BITADDR), offset 0x0A4

The **UART9BITADDR** register is used to write the specific address that should be matched with the receiving byte when the 9-bit Address Mask (**UART9BITAMASK**) is set to 0xFF. This register is used in conjunction with **UART9BITAMASK** to form a match for address-byte received.

UART 9-Bit Self Address (UART9BITADDR)

UART0 base: 0x4000.C000
 UART1 base: 0x4000.D000
 UART2 base: 0x4000.E000
 UART3 base: 0x4000.F000
 UART4 base: 0x4001.0000
 UART5 base: 0x4001.1000
 UART6 base: 0x4001.2000
 UART7 base: 0x4001.3000
 Offset 0x0A4
 Type RW, reset 0x0000.0000

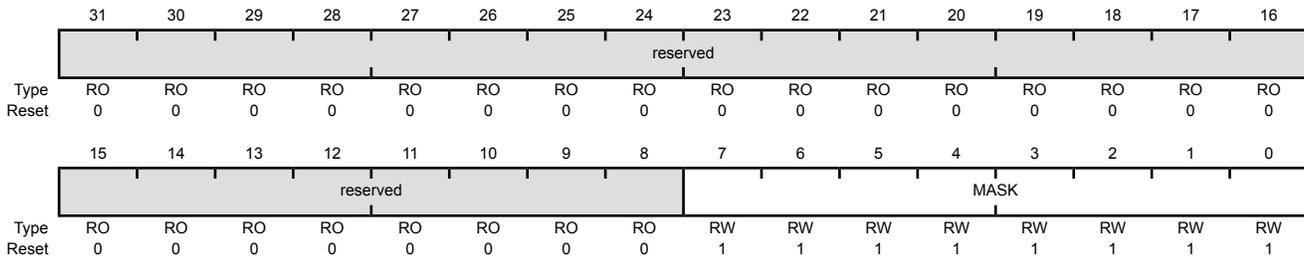

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|--------|---|
| 31:16 | reserved | RO | 0x0000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 15 | 9BITEN | RW | 0 | Enable 9-Bit Mode Value Description 0 9-bit mode is disabled. 1 9-bit mode is enabled. |
| 14:8 | reserved | RO | 0x0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 7:0 | ADDR | RW | 0x00 | Self Address for 9-Bit Mode This field contains the address that should be matched when UART9BITAMASK is 0xFF. |

Register 16: UART 9-Bit Self Address Mask (UART9BITAMASK), offset 0x0A8

The **UART9BITAMASK** register is used to enable the address mask for 9-bit mode. The address bits are masked to create a set of addresses to be matched with the received address byte.

UART 9-Bit Self Address Mask (UART9BITAMASK)

UART0 base: 0x4000.C000
 UART1 base: 0x4000.D000
 UART2 base: 0x4000.E000
 UART3 base: 0x4000.F000
 UART4 base: 0x4001.0000
 UART5 base: 0x4001.1000
 UART6 base: 0x4001.2000
 UART7 base: 0x4001.3000
 Offset 0x0A8
 Type RW, reset 0x0000.00FF

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|-------|---|
| 31:8 | reserved | RO | 0x00 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 7:0 | MASK | RW | 0xFF | Self Address Mask for 9-Bit Mode This field contains the address mask that creates a set of addresses that should be matched. |

Register 17: UART Peripheral Properties (UARTPP), offset 0xFC0

The **UARTPP** register provides information regarding the properties of the UART module.

UART Peripheral Properties (UARTPP)

UART0 base: 0x4000.C000
 UART1 base: 0x4000.D000
 UART2 base: 0x4000.E000
 UART3 base: 0x4000.F000

| | | | | 0 The UART module does not provide smart card support. |
| | | | | 1 The UART module provides smart card support. |

Register 18: UART Clock Configuration (UARTCC), offset 0xFC8

The **UARTCC** register controls the baud clock source for the UART module. For more information, see the section called “Peripheral Clock Sources” on page 245.

Note: If the PIOSC is used for the UART baud clock, the system clock frequency must be at least 9 MHz in Run mode.

UART Clock Configuration (UARTCC)

UART0 base: 0x4000.C000
 UART1 base: 0x4000.D000
 UART2 base: 0x4000.E000

20 Quad Synchronous Serial Interface (QSSI)

The TM4C129XKCZAD microcontroller includes four Quad-Synchronous Serial Interface (QSSI) modules. All four of the modules support Advanced and Bi-SSI interfaces as well as a Quad-SSI enhancement to provide faster throughput of data. The QSSI module acts as a master or slave interface for synchronous serial communication with peripheral devices that have either Freescale SPI, or Texas Instruments synchronous serial interfaces. The QSSI performs serial-to-parallel conversion on data received from a peripheral device. The transmit and receive paths are buffered with internal, independent FIFO memories allowing up to eight 16-bit values in Legacy mode and 8-bit values in Advanced, Bi-, and Quad-modes. The CPU can access data in these FIFOs as well as the QSSI's control and status information. A μ DMA interface is also provided to allow the transmit and receive FIFOs to be programmed as source/destination addresses in the μ DMA module.

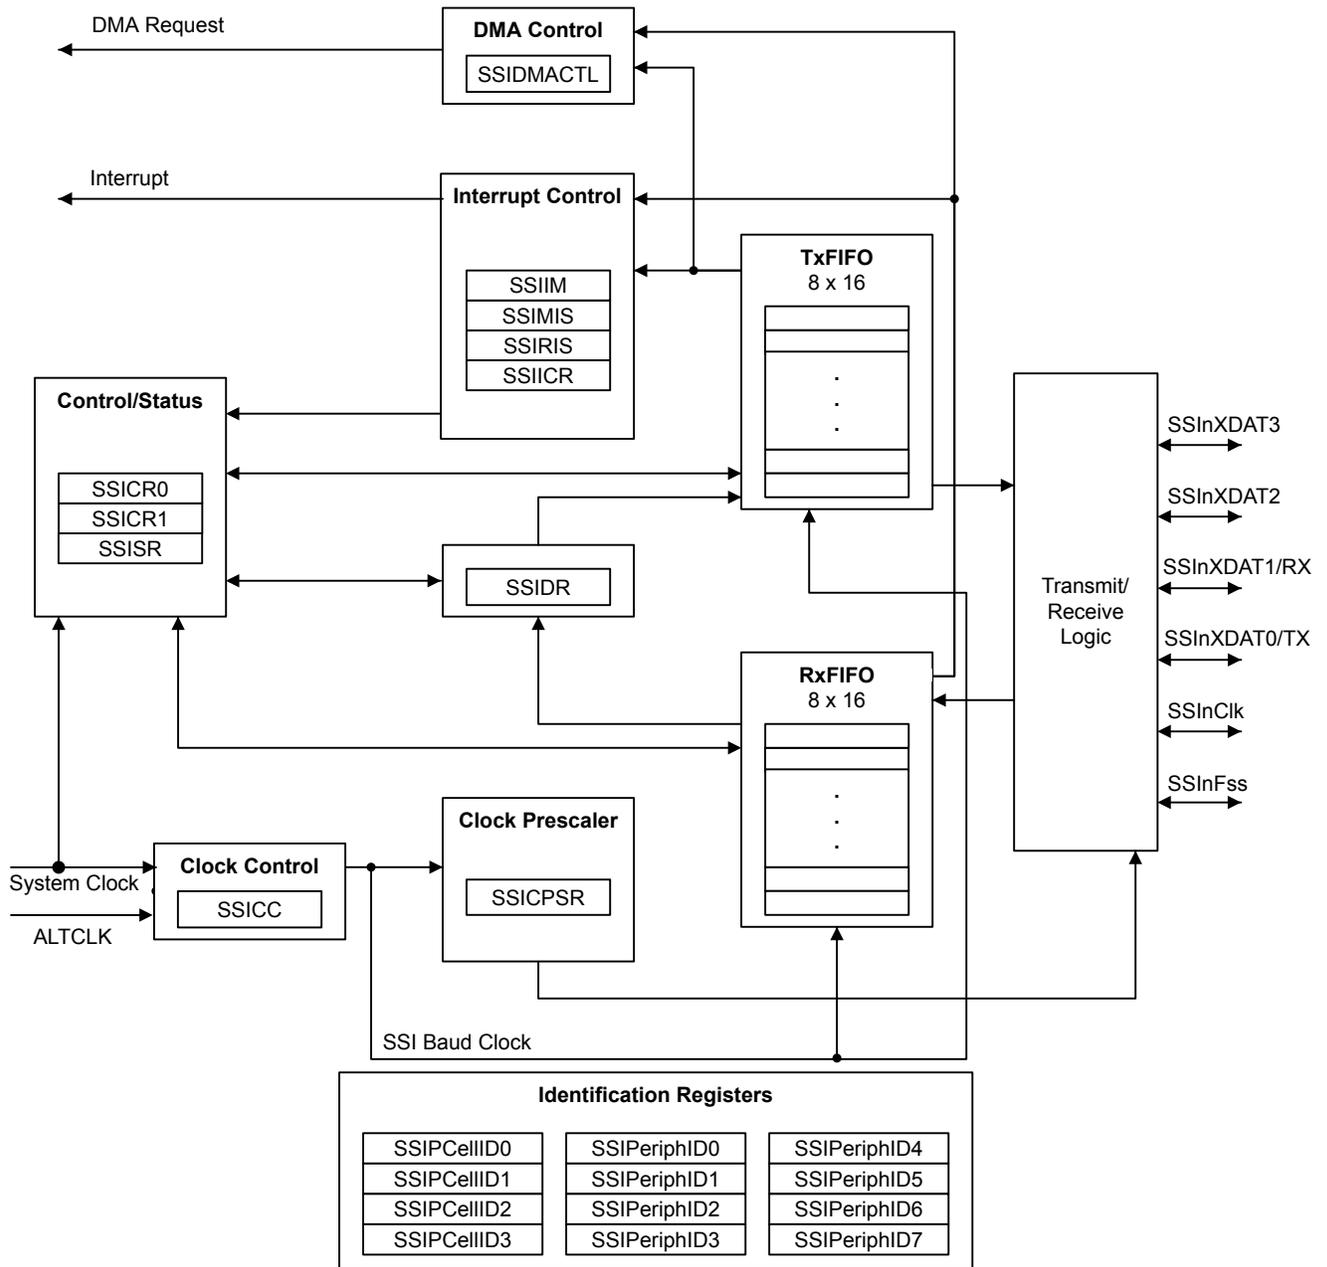

The TM4C129XKCZAD QSSI modules have the following features:

- Four QSSI channels with Advanced, Bi- and Quad-SSI functionality
- Programmable interface operation for Freescale SPI or Texas Instruments synchronous serial interfaces in Legacy Mode. Support for Freescale interface in Bi- and Quad-SSI mode.
- Master or slave operation
- Programmable clock bit rate and prescaler
- Separate transmit and receive FIFOs, each 16 bits wide and 8 locations deep
- Programmable data frame size from 4 to 16 bits
- Internal loopback test mode for diagnostic/debug testing
- Standard FIFO-based interrupts and End-of-Transmission interrupt
- Efficient transfers using Micro Direct Memory Access Controller (μ DMA)
 - Separate channels for transmit and receive
 - Receive single request asserted when data is in the FIFO; burst request asserted when FIFO contains 4 entries
 - Transmit single request asserted when there is space in the FIFO; burst request asserted when four or more entries are available to be written in the FIFO
 - Maskable μ DMA interrupts for receive and transmit complete
- Global Alternate Clock (ALTCLK) resource or System Clock (SYSCLK) can be used to generate baud clock.

20.1 Block Diagram

The following figure below shows a block diagram of an QSSI module with Advanced, Bi- and Quad-SSI.

Figure 20-1. QSSI Module with Advanced, Bi-SSI and Quad-SSI Support

20.2 Signal Description

The following table lists the external signals of the QSSI module and describes the function of each. The QSSI signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The "Pin Mux/Pin Assignment" column in the following table lists the possible GPIO pin placements for the QSSI signals. The **AFSEL** bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 803) should be set to choose the QSSI function. The number in

parentheses is the encoding that must be programmed into the PMC_n field in the **GPIO Port Control (GPIOPCTL)** register (page 820) to assign the QSSI signal to the specified GPIO port pin. For more information on configuring GPIOs, see “General-Purpose Input/Outputs (GPIOs)” on page 772. Note that for the QSSI module, when operating in Legacy Mode, SSI_nXDAT0 functions as SSI_nTX and SSI_nXDAT1 functions as SSI_nRX .

Table 20-1. SSI Signals (212BGA)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description |
|-----------|------------|--------------------------|----------|-------------|--|

20.3 Functional Description

The QSSI performs serial-to-parallel conversion on data received from a peripheral device. The CPU accesses data, control, and status information. The transmit and receive paths are buffered with internal FIFO memories allowing up to eight 16-bit values to be stored independently in both transmit and receive modes. The QSSI also supports the μ DMA interface. The transmit and receive FIFOs can be programmed as destination/source addresses in the μ DMA module. μ DMA operation is enabled by setting the appropriate bit(s) in the **SSIDMACTL** register (see page 1412).

20.3.1 Bit Rate Generation

The QSSI includes a programmable bit rate clock divider and prescaler to generate the serial output clock. Bit rates are supported to 2 MHz and higher, although maximum bit rate is determined by peripheral devices.

The serial bit rate is derived by dividing down the input clock (SysClk). The clock is first divided by an even prescale value **CPSDVSR** from 2 to 254, which is programmed in the **SSI Clock Prescale (SSICPSR)** register (see page 1404). The clock is further divided by a value from 1 to 256, which is $1 + \text{SCR}$, where **SCR** is the value programmed in the **SSI Control 0 (SSICR0)** register (see page 1397).

The frequency of the output clock **SSInClk** is defined by:

$$\text{SSInClk} = \text{SysClk} / (\text{CPSDVSR} * (1 + \text{SCR}))$$

Note: SYSCLK or ALTCLK is used as the source for the **SSInClk** depending on how the **CS** field in the **SSI Clock Configuration (SSICC)** register is configured. For master legacy mode, the SYSCLK or ALTCLK must be at least two times faster than the **SSInClk**, with the restriction that **SSInClk** cannot be faster than 60 MHz. For slave mode, SYSCLK or ALTCLK must be at least 12 times faster than the **SSInClk**. In slave legacy mode, the maximum frequency of **SSInClk** is 10 MHz.

See “Synchronous Serial Interface (SSI)” on page 2144 to view legacy SSI and QSSI timing parameters.

20.3.2 FIFO Operation

20.3.2.1 Transmit FIFO

The common transmit FIFO is a 16-bit wide, 8-locations deep, first-in, first-out memory buffer. The CPU writes data to the FIFO by writing the **SSI Data (SSIDR)** register (see page 1401), and data is stored in the FIFO until it is read out by the transmission logic.

When configured as a master or a slave, parallel data is written into the transmit FIFO prior to a legacy SSI serial conversion and transmission to the attached slave or master, respectively, through the **SSInDAT0/SSInTX** pin.

In slave mode, the legacy SSI transmits data each time the master initiates a transaction. If the transmit FIFO is empty and the master initiates, the slave transmits the 8th most recent value in the transmit FIFO. If less than 8 values have been written to the transmit FIFO since the SSI module clock was enabled using the **Rn** bit in the **RCGCSSI** register or if the QSSI is reset using the **SRSSI** register, then 0 is transmitted. Care should be taken to ensure that valid data is in the FIFO as needed. The QSSI can be configured to generate an interrupt or a μ DMA request when the FIFO is empty.

Note: When operating in Legacy Mode, the QuadSSI's **SSInXDAT0** signal functions as **SSInTX**.

20.3.2.2 Receive FIFO

The common receive FIFO is a 16-bit wide, 8-locations deep, first-in, first-out memory buffer. Received data using the legacy serial interface is stored in the buffer until read out by the CPU, which accesses the read FIFO by reading the **SSIDR** register. If the receive FIFO is full when the master or slave receives new data, the data is held off until the receive FIFO has space.

The SSI only provides an SSIClk while transmitting data. When receiving data in master mode, a dummy write to the **SSIDR** register must be performed before any read so that the SSIClk can be properly received by the slave and allow data to be sent to the receive FIFO of the master.

When configured as a master or slave, serial data received through the **SSInDAT1/SSInRX** pin is registered prior to parallel loading into the attached slave or master receive FIFO, respectively.

Note: When operating in Legacy Mode, the QSSI's **SSInXDAT1** signal functions as **SSInRX**.

20.3.3 Advanced, Bi- and Quad- SSI Function

Bi-SSI uses two data pins, **SSInXDAT0** and **SSInXDAT1**, that can be configured to receive or transmit data. In Quad-SSI mode, **SSInXDAT0**, **SSInXDAT1**, **SSInXDAT2** and **SSInXDAT3** allow four bits of data to be received or transmitted at once. Note that in bi- and quad-SSI data transfers are only half-duplex.

By programming the **MODE** bits in the **SSICR1** register, Advanced, Bi- or Quad- SSI can be enabled. A direction bit, **DIR**, is provided to program the direction of operation during a Bi- or Quad SSI-transaction. Since Bi- and Quad-SSI cannot be full duplex, the **DIR** bit defines whether or not the RX FIFO is disabled. In Advanced operation, if the QSSI module TX (write) mode is enabled, the RX FIFO is automatically prevented from receiving any data. When Advanced SSI is in RX (read) mode, it operates as a full-duplex interface.

In Bi- and Quad-SSI mode, because only 8-bit data is allowed, the **DSS** bit field must be programmed to 0x7 in the **SSICR0** register before transferring data to the Rx and TX FIFOs. For a data transmit, the 8-bit data packet is placed in a TX FIFO entry bits [7:0] and the mode of operation is inserted in the three most significant bits of the TX FIFO entry. The mode of operation bits [15:13] in the TX FIFO are used by the QSSI module for configuring the data on the proper pins. The following modes that may be placed on bits [15:13] of the FIFO entry are:

- Bi-SSI mode (0x1)
- Quad-SSI mode (0x2)
- Advanced SSI mode (0x3)

When data is first written to the TX FIFO, a **SSInFSS** is asserted low indicating the start of a frame. At the end of transmission, bit 12 of the last data entry in the TX FIFO signifies whether a a frame is ending. When the **EOM** bit is 1 it indicates a End of Message (EOM or STOP frame) and **SSInFSS** is subsequently forced high. The **EOM** bit is cleared in the **SSICR1** register on the same clock that the write to TXFIFO is completed. An **EOM** bit value of 0 indicates no change in transmission. If TX FIFO is emptied and **SSInFSS** is still asserted low, it remains low but **SSInCLK** is not pulsed. Likewise, if **SSInFSS** is high when the TX FIFO is empty, it remains high.

During a Bi-SSI transmit frame, data is shifted out by two bits and placed on the corresponding two **SSInDATn** pins. For a Quad-SSI transmit frame data is shifted out by four bits and placed on the corresponding four **SSInDATn** pins.

In Bi-, Quad- and Advanced SSI, the lower byte of the Rx FIFO contains received data. The upper byte contains no valid information.

Note: While the master is in Bi- or Quad-SSI mode, if the `DSS` bit in the **SSICR0** register is not set to 0x7, the QSSI module reverts to Legacy mode and behavior is not guaranteed.

The **SSICR1** register bits `DIR` and `MODE` are used to program what operation is needed for the next data bytes that are being loaded into the FIFO. Table 20-2 on page 1383 shows available modes of operation:

Table 20-2. QSSI Transaction Encodings

| DIR | MODE | Operation |
|-----|------|---|
| X | 0x0 | SSI Legacy operation supporting 4 to 16 data bits |
| 0 | 0x1 | Transmit (TX) Bi-SSI with 8-bits of packet data |
| 0 | 0x2 | Transmit (TX) Quad-SSI with 8-bits of packet data |
| 0 | 0x3 | Transmit (TX) Advanced SSI mode with 8-bits of packet data and write RX FIFO disabled |
| 1 | 0x1 | Receive (RX) Bi-SSI with 8-bits of packet data |
| 1 | 0x2 | Receive (RX) Quad-SSI with 8-bits of packet data |
| 1 | 0x3 | Full duplex Advance SSI with 8-bits of packet data |

Note: `SPO = 0` and `SPH = 0` is the only frame structure allowed for Advanced, Bi- and Quad-mode.

Different transactions can follow one another in the FIFOs. The following transaction combinations are allowed:

- Legacy SSI mode (if configured for this mode, switching to any other alternate mode is not recommended)
- Advanced SSI mode followed by Bi-SSI mode
- Advanced SSI mode followed by Quad-SSI mode
- Advanced SSI mode followed by Bi-SSI mode followed by Advanced SSI mode
- Advanced SSI mode followed by Quad-SSI mode followed by Advanced SSI mode

Note that switching between Quad-SSI and Bi-SSI is not encouraged in a single transaction.

20.3.4 SSInFSS Function

For enhanced modes of operation, the `SSInFSS` signal can be programmed to assert low at the start of each byte transfer for one clock or the entire frame. This is configured by programming the `FSSHLDFRM` bit in the **SSICR1** register. The `EOM` bit is also provided to signify end of frame transmission. This bit is embedded in the TXFIFO entry for use at the interface to deassert `SSInFSS` at the appropriate time. The `FSSHLDFRM` bit can also be used when operating in 8-bit Legacy SSI mode.

The functionality of the `FSSHLDFRM` bit for both Legacy SSI mode and the enhanced modes are as follows:

Table 20-3. SSInFss Functionality

| Mode | FSSHDFRM | Description |
|----------------------------|----------|---|
| Legacy Mode | 0 | For Freescale format, with <i>SPH</i> = 0, the <i>SSInFss</i> signal is asserted low between continuous transfers. For <i>SPH</i> = 1, the <i>SSInFss</i> signal is deasserted (high) between continuous transfers. For TI format, the <i>SSInFss</i> signal is deasserted (high) after every data transfer. |
| | 1 | For Freescale format with any <i>SPH</i> value, the <i>SSInFss</i> signal is forced high between continuous transfers; it is asserted low when there is available data in the Tx FIFO; otherwise it is forced high to be ready for a new frame |
| Advanced/Bi-/Quad-SSI Mode | 0 | <i>SSInFss</i> is asserted low after every byte of data |
| | 1 | New data written to the TX FIFO notifies <i>SSInFss</i> to assert low until the Tx FIFO is empty. |

20.3.5 High Speed Clock Operation

In master mode, QSSI module can enable a high speed clock by setting the *HSCLKEN* bit in the **SSI Control 1 (SSICR1)** register. In this mode of operation, *SSInCLK* from the QSSI master operation is reflected back as a loopback clock, *HSPEEDCLK*, to the QSSI module. This allows faster timing since the logic can be used to adjust clock to external data relationships. *HSPEEDCLK* captures RX data in a separate register. This allows the time between the clock as seen by a remote device and the internal clock to match more closely.

Receive data is captured in a separate register sampled on loop-back clock (*HSPEEDCLK*) and the RX FIFO write control registered on *HSPEEDCLK*. If the *HSCKEN* = 1, the corresponding shift register and FIFO write enable will be selected for use. This supports faster QSSI master speed.

Note: For proper functionality of high speed mode, the *HSCLKEN* bit in the **SSICR1** register should be set before any SSI data transfer or after applying a reset to the QSSI module. In addition, the *SSE* bit must be set to 0x1 before the *HSCLKEN* bit is set.

20.3.6 Interrupts

The QSSI can generate interrupts when the following conditions are observed:

- Transmit FIFO service (when the transmit FIFO is half full or less)
- Receive FIFO service (when the receive FIFO is half full or more)
- Receive FIFO time-out
- Receive FIFO overrun
- End of transmission
- Receive DMA transfer complete
- Transmit DMA transfer complete

All of the interrupt events are ORed together before being sent to the interrupt controller, so the QSSI generates a single interrupt request to the controller regardless of the number of active interrupts. Each of the seven individual maskable interrupts can be masked by clearing the appropriate bit in the **SSI Interrupt Mask (SSIIM)** register (see page 1405). Setting the appropriate mask bit enables the interrupt.

The individual outputs, along with a combined interrupt output, allow use of either a global interrupt service routine or modular device drivers to handle interrupts. The transmit and receive dynamic dataflow interrupts have been separated from the status interrupts so that data can be read or written in response to the FIFO trigger levels. The status of the individual interrupt sources can be read from the **SSI Raw Interrupt Status (SSIRIS)** and **SSI Masked Interrupt Status (SSIMIS)** registers (see page 1407 and page 1409, respectively).

The RX FIFO has an associated time-out counter which starts to down count at the same time the RX FIFO is flagged as not empty by the `RNE` bit in the **SSISR** register. The counter is reset any time a new or next byte is written to the RX FIFO, thus the counter will continue to count down to zero unless there is new activity. The time-out period is 32 periods based on the period of `SSInClk`. When the counter reaches zero, a time-out interrupt bit, `RTRIS`, is set in the **SSIRIS** register. The time-out interrupt can be cleared by writing a 1 to the `RTIC` bit of the **SSI Interrupt Clear (SSIC)** register or by emptying the RX FIFO. If the interrupt is cleared and there is residual data left in the RX FIFO or new data entries have been written, the timer count down initiates and the interrupt will be reasserted after 32 periods have been counted.

The End-of-Transmission (EOT) interrupt indicates that the data has been transmitted completely and is only valid for Master mode devices/operations. This interrupt can be used to indicate when it is safe to turn off the QSSI module clock or enter sleep mode. In addition, because transmitted data and received data complete at exactly the same time, the interrupt can also indicate that read data is ready immediately, without waiting for the receive FIFO time-out period to complete.

Note: In Freescale SPI mode only, a condition can be created where an EOT interrupt is generated for every byte transferred even if the FIFO is full. If the the μ DMA has been configured to transfer data from this QSSI to a Master QSSI on the device using external loopback, an EOT interrupt is generated by the QSSI slave for every byte even if the FIFO is full.

20.3.7 Frame Formats

Each data frame is between 4 and 16 bits long in Legacy mode and 8-bits in Advanced/Bi-/Quad-SSI mode and is transmitted starting with the MSB. There are two basic frame types that can be selected by programming the `FRF` bit in the **SSICR0** register:

- Texas Instruments synchronous serial
- Freescale SPI

Note: Advanced, Bi- and Quad-SSI modules only supports Freescale mode when `SPH=0`; `SPO=0` and `DDS=0x8` in the **SSI Control 0 (SSICR0)** register.

For both formats, the serial clock (`SSInClk`) is held inactive while the QSSI is idle, and `SSInClk` transitions at the programmed frequency only during active transmission or reception of data. The idle state of `SSInClk` is utilized to provide a receive timeout indication that occurs when the receive FIFO still contains data after a timeout period.

For Freescale SPI frame format, the serial frame (`SSInFss`) pin is active Low, and is asserted (pulled down) during the entire transmission of the frame.

For Texas Instruments synchronous serial frame format, the `SSInFss` pin is pulsed for one serial clock period starting at its rising edge, prior to the transmission of each frame. For this frame format, both the QSSI and the off-chip slave device drive their output data on the rising edge of `SSInClk` and latch data from the other device on the falling edge.

The following table gives a synopsis of the features supported in each frame format when operating in Legacy Mode:

Table 20-4. Legacy Mode TI, Freescale SPI Frame Format Features

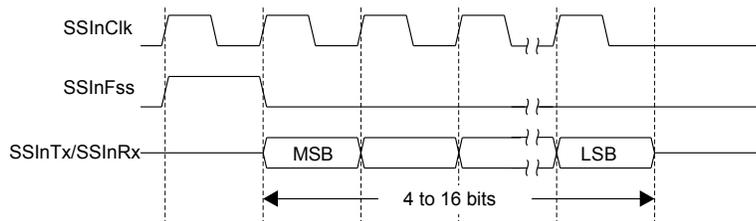

| Feature | TI Mode | Freescale SPI Mode |
|------------------------------------|--------------------------|--|
| Frame Hold | Not Available | Available |
| High Speed (Master RX Only) | Not Available | Available |
| SPO/SPH Configuration | Not Available | Available and can be used in combination with Frame Hold and High Speed Mode |
| Frequency (system clock : SSInCLK) | Master 1:2 Slave 1:12 | Master 1:2 Slave 1:12 |

For Advanced, Bi- and Quad-SSI modes using the Freescale SPI Format or the Bi- and Quad-SSI modes using the TI format, the following features are supported:

- Frame Hold
- High Speed (Master RX Only)
- SPO/SPH Configuration with $SPO=0$ and $SPH=0$ only allowed
- Frequency (system clock : SSInCLK):
 - Master 1:2
 - Slave 1:12

20.3.7.1 Texas Instruments Synchronous Serial Frame Format

Figure 20-2 on page 1386 shows the Texas Instruments synchronous serial frame format for a single transmitted frame.

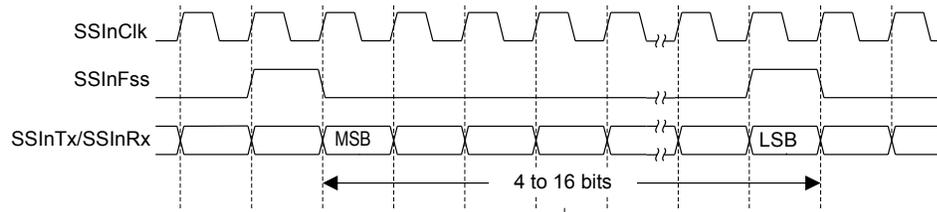

Figure 20-2. TI Synchronous Serial Frame Format (Single Transfer)

In this mode, SSInClk and SSInFss are forced Low, and the transmit data line SSInDAT0/SSInTX is tristated whenever the QSSI is idle. Once the bottom entry of the transmit FIFO contains data, SSInFss is pulsed High for one SSInClk period. The value to be transmitted is also transferred from the transmit FIFO to the serial shift register of the transmit logic. On the next rising edge of SSInClk, the MSB of the 4 to 16-bit data frame is shifted out on the SSInDAT0/SSInTX pin. Likewise, the MSB of the received data is shifted onto the SSInDAT1/SSInRX pin by the off-chip serial slave device.

Both the QSSI and the off-chip serial slave device then clock each data bit into their serial shifter on each falling edge of SSInClk. The received data is transferred from the serial shifter to the receive FIFO on the first rising edge of SSInClk after the LSB has been latched.

Figure 20-3 on page 1387 shows the Texas Instruments synchronous serial frame format when back-to-back frames are transmitted.

Figure 20-3. TI Synchronous Serial Frame Format (Continuous Transfer)

20.3.7.2 Freescale SPI Frame Format

The Freescale SPI interface is a four-wire interface where the `SSInFss` signal behaves as a slave select. If operating in Legacy Mode and using the Freescale SPI Frame Format, the inactive state and phase of the `SSInClk` signal are programmable through the `SPO` and `SPH` bits in the `SSICR0` control register. If operating in Advanced/Bi-/Quad-SSI mode, the `SPO` and `SPH` bits must be programmed to 0.

SPO Clock Polarity Bit

When the `SPO` clock polarity control bit is clear, it produces a steady state Low value on the `SSInClk` pin. If the `SPO` bit is set, a steady state High value is placed on the `SSInClk` pin when data is not being transferred.

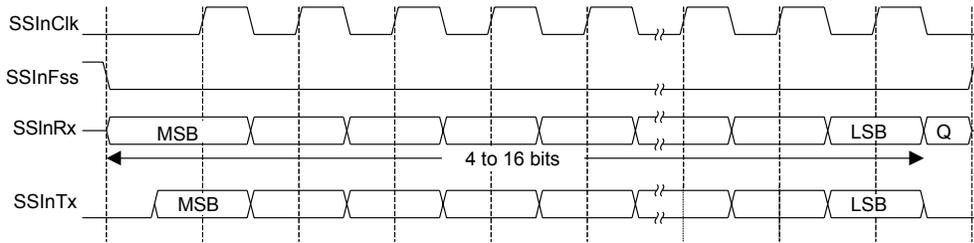

SPH Phase Control Bit

The `SPH` phase control bit selects the clock edge that captures data and allows it to change state. The state of this bit has the most impact on the first bit transmitted by either allowing or not allowing a clock transition before the first data capture edge. When the `SPH` phase control bit is clear, data is captured on the first clock edge transition. If the `SPH` bit is set, data is captured on the second clock edge transition.

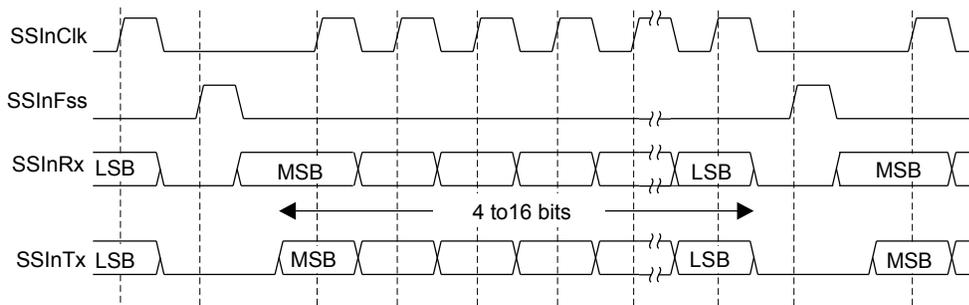

20.3.7.3 Freescale SPI Frame Format with `SPO=0` and `SPH=0`

Single and continuous transmission signal sequences for Freescale SPI format with `SPO=0` and `SPH=0` are shown in Figure 20-4 on page 1388 and Figure 20-5 on page 1388.

Note: This is the only Freescale SPI frame format configuration that can be used when operating in Advanced/Bi-/Quad-SSI mode.

Figure 20-4. Freescale SPI Format (Single Transfer) with SPO=0 and SPH=0

Note: Q is undefined.

Figure 20-5. Freescale SPI Format (Continuous Transfer) with SPO=0 and SPH=0

In this configuration, during idle periods:

- SSInClk is forced Low
- SSInFss is forced High
- The transmit data line SSInDAT0/SSInTX is tristated
- When the QSSI is configured as a master, it enables the SSInClk pad
- When the QSSI is configured as a slave, it disables the SSInClk pad

If the QSSI is enabled and valid data is in the transmit FIFO, the start of transmission is signified by the SSInFss master signal being driven Low, causing slave data to be enabled onto the SSInDAT1/SSInRX input line of the master. The master SSInDAT0/SSInTX output pad is enabled.

One half SSInClk period later, valid master data is transferred to the SSInDAT0/SSInTX pin. Once both the master and slave data have been set, the SSInClk master clock pin goes High after one additional half SSInClk period.

The data is now captured on the rising and propagated on the falling edges of the SSInClk signal.

In the case of a single word transmission, after all bits of the data word have been transferred, the `SSInFss` line is returned to its idle High state one `SSInClk` period after the last bit has been captured.

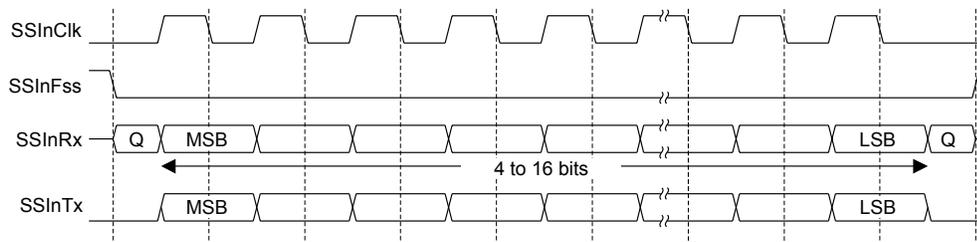

However, in the case of continuous back-to-back transmissions, the `SSInFss` signal must be pulsed High between each data word transfer because the slave select pin freezes the data in its serial peripheral register and does not allow it to be altered if the `SPH` bit is clear. Therefore, the master device must raise the `SSInFss` pin of the slave device between each data transfer to enable the serial peripheral data write. On completion of the continuous transfer, the `SSInFss` pin is returned to its idle state one `SSInClk` period after the last bit has been captured.

20.3.7.4 Freescale SPI Frame Format with `SPO=0` and `SPH=1`

The transfer signal sequence for Freescale SPI format with `SPO=0` and `SPH=1` is shown in Figure 20-6 on page 1389, which covers both single and continuous transfers.

Note: This Freescale SPI frame format configuration is only available when operating in Legacy SSI mode of operation.

Figure 20-6. Freescale SPI Frame Format with `SPO=0` and `SPH=1`

Note: Q is undefined.

In this configuration, during idle periods:

- `SSInClk` is forced Low
- `SSInFss` is forced High
- The transmit data line `SSInDAT0/SSInTX` is tristated
- When the QSSI is configured as a master, it enables the `SSInClk` pad
- When the QSSI is configured as a slave, it disables the `SSInClk` pad

If the QSSI is enabled and valid data is in the transmit FIFO, the start of transmission is signified by the `SSInFss` master signal being driven Low. The master `SSInDAT0/SSInTX` output is enabled. After an additional one-half `SSInClk` period, both master and slave valid data are enabled onto their respective transmission lines. At the same time, the `SSInClk` is enabled with a rising edge transition.

Data is then captured on the falling edges and propagated on the rising edges of the `SSInClk` signal.

In the case of a single word transfer, after all bits have been transferred, the $SSInFss$ line is returned to its idle High state one $SSInClk$ period after the last bit has been captured.

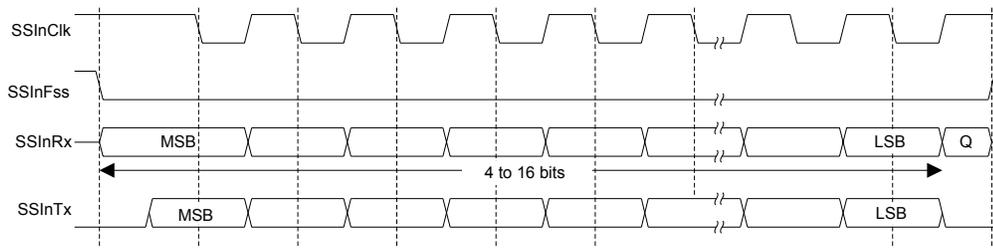

For continuous back-to-back transfers, the $SSInFss$ pin is held Low between successive data words, and termination is the same as that of the single word transfer.

20.3.7.5 Freescale SPI Frame Format with $SPO=1$ and $SPH=0$

Single and continuous transmission signal sequences for Freescale SPI format with $SPO=1$ and $SPH=0$ are shown in Figure 20-7 on page 1390 and Figure 20-8 on page 1390.

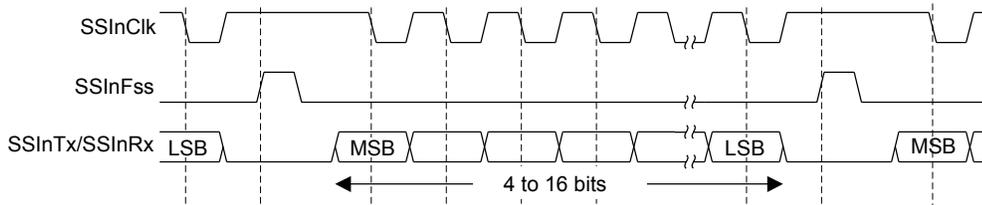

Note: This Freescale SPI frame format configuration is only available when operating in Legacy SSI mode of operation.

Figure 20-7. Freescale SPI Frame Format (Single Transfer) with $SPO=1$ and $SPH=0$

Note: Q is undefined.

Figure 20-8. Freescale SPI Frame Format (Continuous Transfer) with $SPO=1$ and $SPH=0$

In this configuration, during idle periods:

- $SSInClk$ is forced High
- $SSInFss$ is forced High
- The transmit data line $SSInDAT0/SSInTX$ is tristated
- When the QSSI is configured as a master, it enables the $SSInClk$ pad
- When the QSSI is configured as a slave, it disables the $SSInClk$ pad

If the QSSI is enabled and valid data is in the transmit FIFO, the start of transmission is signified by the `SSInFss` master signal being driven Low, causing slave data to be immediately transferred onto the `SSInDAT1/SSInRX` line of the master. The master `SSInDAT0/SSInTX` output pad is enabled.

One-half period later, valid master data is transferred to the `SSInDAT0/SSInTX` line. Once both the master and slave data have been set, the `SSInClk` master clock pin becomes Low after one additional half `SSInClk` period, meaning that data is captured on the falling edges and propagated on the rising edges of the `SSInClk` signal.

In the case of a single word transmission, after all bits of the data word are transferred, the `SSInFss` line is returned to its idle High state one `SSInClk` period after the last bit has been captured.

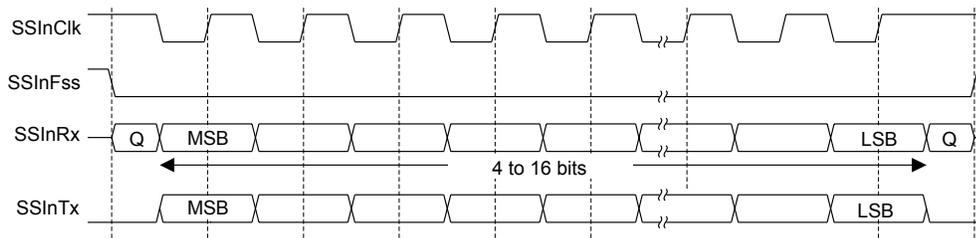

However, in the case of continuous back-to-back transmissions, the `SSInFss` signal must be pulsed High between each data word transfer because the slave select pin freezes the data in its serial peripheral register and does not allow it to be altered if the `SPH` bit is clear. Therefore, the master device must raise the `SSInFss` pin of the slave device between each data transfer to enable the serial peripheral data write. On completion of the continuous transfer, the `SSInFss` pin is returned to its idle state one `SSInClk` period after the last bit has been captured.

20.3.7.6 Freescale SPI Frame Format with `SPO=1` and `SPH=1`

The transfer signal sequence for Freescale SPI format with `SPO=1` and `SPH=1` is shown in Figure 20-9 on page 1391, which covers both single and continuous transfers.

Note: This Freescale SPI frame format configuration is only available when operating in Legacy SSI mode of operation.

Figure 20-9. Freescale SPI Frame Format with `SPO=1` and `SPH=1`

Note: Q is undefined.

In this configuration, during idle periods:

- `SSInClk` is forced High
- `SSInFss` is forced High
- The transmit data line `SSInDAT0/SSInTX` is tristated
- When the QSSI is configured as a master, it enables the `SSInClk` pad
- When the QSSI is configured as a slave, it disables the `SSInClk` pad

If the QSSI is enabled and valid data is in the transmit FIFO, the start of transmission is signified by the `SSInFss` master signal being driven Low. The master `SSInDAT0/SSInTX` output pad is enabled. After an additional one-half `SSInClk` period, both master and slave data are enabled onto their respective transmission lines. At the same time, `SSInClk` is enabled with a falling edge transition. Data is then captured on the rising edges and propagated on the falling edges of the `SSInClk` signal.

After all bits have been transferred, in the case of a single word transmission, the `SSInFss` line is returned to its idle high state one `SSInClk` period after the last bit has been captured.

For continuous back-to-back transmissions, the `SSInFss` pin remains in its active Low state until the final bit of the last word has been captured and then returns to its idle state as described above.

For continuous back-to-back transfers, the `SSInFss` pin is held Low between successive data words and termination is the same as that of the single word transfer.

20.3.8 DMA Operation

The QSSI peripheral provides an interface to the μ DMA controller with separate channels for transmit and receive. The μ DMA operation of the QSSI is enabled through the **SSI DMA Control (SSIDMACTL)** register. When μ DMA operation is enabled, the QSSI asserts a μ DMA request on the receive or transmit channel when the associated FIFO can transfer data.

For the receive channel, a single transfer request is asserted whenever any data is in the receive FIFO. A burst transfer request is asserted whenever the amount of data in the receive FIFO is 4 or more items. For the transmit channel, a single transfer request is asserted whenever at least one empty location is in the transmit FIFO. The burst request is asserted whenever the transmit FIFO has 4 or more empty slots. The single and burst μ DMA transfer requests are handled automatically by the μ DMA controller depending how the μ DMA channel is configured.

To enable μ DMA operation for the receive channel, the `RXDMAE` bit of the **DMA Control (SSIDMACTL)** register should be set after configuring the μ DMA. To enable μ DMA operation for the transmit channel, the `TXDMAE` bit of **SSIDMACTL** should be set after configuring the μ DMA.

If the μ DMA is enabled and has completed a data transfer from the Tx FIFO, the `DMATXRIS` bit is set in the **SSIRIS** register and cannot be cleared by setting the `DMATXIC` bit in the **SSI Interrupt Clear (SSIICR)** register. In the DMA Completion Interrupt Service Routine, software must disable the μ DMA transmit enable to the SSI by clearing the `TXDMAE` bit in the **QSSI DMA Control (SSIDMACTL)** register and then setting the `DMATXIC` bit in the **SSIICR** register. This clears the DMA completion interrupt. When the μ DMA is needed to transmit more data, the `TXDMAE` bit must be set (enabled) again.

If a data transfer by the μ DMA from the Rx FIFO completes, the `DMARXRIS` bit is set. The `EOT` bit in the **SSIRIS** register is also provided to indicate when the Tx FIFO is empty and the last bit has been transmitted out of the serializer.

Note: Wait states are inserted at every byte transfer when using Bi- or Quad-SSI modes as a master with the μ DMA at `SSICLK` frequencies greater than 1/6 of the system clock. These wait states are because of arbitration stall cycles from the μ DMA accesses to SRAM and increased output throughput from the SSI.

See "Micro Direct Memory Access (μ DMA)" on page 708 for more details about programming the μ DMA controller.

20.4 Initialization and Configuration

To enable and initialize the QSSI, the following steps are necessary:

1. Enable the QSSI module using the **RCGCSSI** register (see page 407).
2. Enable the clock to the appropriate GPIO module via the **RCGCGPIO** register (see page 399). To find out which GPIO port to enable, refer to Table 31-5 on page 2081.
3. Set the GPIO **AFSEL** bits for the appropriate pins (see page 803). To determine which GPIOs to configure, see Table 31-4 on page 2064.
4. Configure the **PMCn** fields in the **GPIOPCTL** register to assign the QSSI signals to the appropriate pins. See page 820 and Table 31-5 on page 2081.
5. Program the **GPIODEN** register to enable the pin's digital function. In addition, the drive strength, drain select and pull-up/pull-down functions must be configured. Refer to “General-Purpose Input/Outputs (GPIOs)” on page 772 for more information.

Note: Pull-ups can be used to avoid unnecessary toggles on the QSSI pins, which can take the slave to a wrong state. In addition, if the **SSIClk** signal is programmed to steady state High through the **SPO** bit in the **SSICR0** register, then software must also configure the GPIO port pin corresponding to the **SSInClk** signal as a pull-up in the **GPIO Pull-Up Select (GPIOPUR)** register.

For each of the frame formats, the QSSI is configured using the following steps:

1. If initializing out of reset, ensure that the **SSE** bit in the **SSICR1** register is clear before making any configuration changes. Otherwise, configuration changes for Advanced SSI can be made while the **SSE** bit is set.
2. Select whether the QSSI is a master or slave:
 - a. For master operations, set the **SSICR1** register to 0x0000.0000.
 - b. For slave mode (output enabled), set the **SSICR1** register to 0x0000.0004.
 - c. For slave mode (output disabled), set the **SSICR1** register to 0x0000.000C.
3. Configure the QSSI clock source by writing to the **SSICC** register.
4. Configure the clock prescale divisor by writing the **SSICPSR** register.
5. Write the **SSICR0** register with the following configuration:
 - Serial clock rate (**SCR**)
 - Desired clock phase/polarity, if using Freescale SPI mode (**SPH** and **SPO**)
 - The protocol mode: Freescale SPI or TI SSF
 - The data size (**DSS**)
6. Optionally, configure the SSI module for μ DMA use with the following steps:
 - a. Configure a μ DMA for SSI use. See “Micro Direct Memory Access (μ DMA)” on page 708 for more information.
 - b. Enable the SSI Module's TX FIFO or RX FIFO by setting the **TXDMAE** or **RXDMAE** bit in the **SSIDMACTL** register.

- c. Optionally, enable the μ DMA completion interrupt by setting the `DMATXIM` or `DMARXIM` bit in the **SSIIM** register.

Note: For a TX DMA completion interrupt, software must disable the μ DMA transmit enable to the SSI by clearing the `TXDMAE` bit in the **QSSI DMA Control (SSIDMACTL)** register and then setting the `DMATXIC` bit in the **SSIICR** register. This clears the DMA completion interrupt. When the μ DMA is needed to transmit more data, the `TXDMAE` bit must be set (enabled) again.

- 7. If this is the first initialization out of reset, enable the QSSI by setting the `SSE` bit in the **SSICR1** register.

As an example, assume the QSSI must be configured to operate with the following parameters:

- Master operation
- Freescale SPI mode (`SPO=1`, `SPH=1`)
- 1 Mbps bit rate
- 8 data bits

Assuming the system clock is 20 MHz, the bit rate calculation would be:

$$\begin{aligned} \text{SSInClk} &= \text{SysClk} / (\text{CPSDVSR} * (1 + \text{SCR})) \\ 1 \times 10^6 &= 20 \times 10^6 / (\text{CPSDVSR} * (1 + \text{SCR})) \end{aligned}$$

In this case, if `CPSDVSR=0x2`, `SCR` must be `0x9`.

The configuration sequence would be as follows:

1. Ensure that the `SSE` bit in the **SSICR1** register is clear.
2. Write the **SSICR1** register with a value of `0x0000.0000`.
3. Write the **SSICPSR** register with a value of `0x0000.0002`.
4. Write the **SSICR0** register with a value of `0x0000.09C7`.
5. The QSSI is then enabled by setting the `SSE` bit in the **SSICR1** register.

20.4.1 Enhanced Mode Configuration

If the QSSI module supports the Advanced/Bi-/Quad features, then these modes can be enabled after initializing the QSSI module. Below is an example of configuring the QSSI to transmit two data bytes in Advanced SSI mode followed by 2 bytes in Bi-SSI mode:

1. Set the `MODE` bit to `0x3`, and the `FSSHLDLFM` bit to 1 in the **SSICR1** register. To operate in the master mode, program the `MS` bit to 0. Program the remaining bits in the **SSICR0** and **SSICR1** register to relevant values.
2. Write one data byte to the TX FIFO; set the `EOM` bit to 1 and write the second data byte to the TX FIFO.

3. Set the `MODE` bit to 0x1 and the `FSSHLD` bit to 1 in the **SSICR1** register. To operate in the master mode, program the `MS` bit to 0. Program the remaining bits in the **SSICR0** and **SSICR1** register to relevant values.
4. Fill the Tx FIFO with one data byte.
5. Set the `EOM` bit in the **SSICR1** register.
6. Fill the Tx FIFO with one data byte.

20.5 Register Map

Table 20-5 on page 1395 lists the QSSI registers. The offset listed is a hexadecimal increment to the register's address, relative to that QSSI module's base address:

- QSSI0: 0x4000.8000
- QSSI1: 0x4000.9000
- QSSI2: 0x4000.A000
- QSSI3: 0x4000.B000

Note that the QSSI module clock must be enabled before the registers can be programmed (see page 407). The `Rn` bit of the **PRSSI** register must be read as 0x1 before any QSSI module registers are accessed.

Table 20-5. SSI Register Map

| Offset | Name | Type | Reset | Description | See page |
|--------|--------------|------|-------------|----------------------------------|----------|

20.6 Register Descriptions

The remainder of this section lists and describes the QSSI registers, in numerical order by address offset.

Register 1: QSSI Control 0 (SSICR0), offset 0x000

The **SSICR0** register contains bit fields that control various functions within the QSSI module. Functionality such as protocol mode, clock rate, and data size are configured in this register.

QSSI Control 0 (SSICR0)

QSSI0 base: 0x4000.8000
 QSSI1 base: 0x4000.9000
 QSSI2 base: 0x4000.A000
 QSSI3 base: 0x4000.B000
 Offset 0x000
 Type RW, reset 0x0000.0000

Register 3: QSSI Data (SSIDR), offset 0x008

Important: This register is read-sensitive. See the register description for details.

The **SSIDR** register is 16-bits wide. When the **SSIDR** register is read, the entry in the receive FIFO that is pointed to by the current FIFO read pointer is accessed. When a data value is removed by the QSSI receive logic from the incoming data frame, it is placed into the entry in the receive FIFO pointed to by the current FIFO write pointer.

When the **SSIDR** register is written to, the entry in the transmit FIFO that is pointed to by the write pointer is written to. Data values are removed from the transmit FIFO one value at a time by the transmit logic. Each data value is loaded into the transmit serial shifter, then serially shifted out onto the **SSInDAT0/SSInTX** pin at the programmed bit rate.

When a data size of less than 16 bits is selected, the user must right-justify data written to the transmit FIFO. The transmit logic ignores the unused bits. Received data less than 16 bits is automatically right-justified in the receive buffer.

QSSI Data (SSIDR)

QSSI0 base: 0x4000.8000
 QSSI1 base: 0x4000.9000
 QSSI2 base: 0x4000.A000
 QSSI3 base: 0x4000.B000
 Offset 0x008
 Type RW, reset 0x0000.0000

| 0 | TFE | RO | 1 | QSSI Transmit FIFO Empty |
| | | | | Value Description |
| | | | | 0 The transmit FIFO is not empty. |
| | | | | 1 The transmit FIFO is empty. |

Register 5: QSSI Clock Prescale (SSICPSR), offset 0x010

The **SSICPSR** register specifies the division factor which is used to derive the **SSInClk** from the system clock. The clock is further divided by a value from 1 to 256, which is $1 + SCR$. **SCR** is programmed in the **SSICR0** register. The frequency of the **SSInClk** is defined by:

$$SSInClk = SysClk / (CPSDVSR * (1 + SCR))$$

The value programmed into this register must be an even number between 2 and 254. The least-significant bit of the programmed number is hard-coded to zero. If an odd number is written to this register, data read back from this register has the least-significant bit as zero.

QSSI Clock Prescale (SSICPSR)

QSSI0 base: 0x4000.8000
 QSSI1 base: 0x4000.9000
 QSSI2 base: 0x4000.A000
 QSSI3 base: 0x4000.B000
 Offset 0x010
 Type RW, reset 0x0000.0000

| | | | | | | | | | | | | | | | | |
|-------|----------|----|----|----|----|----|----|----|---------|----|----|----|----|----|----|----|
| | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|-------|---|
| 31:8 | reserved | RO | 0x00 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 7:0 | CPSDVSR | RW | 0x00 | QSSI Clock Prescale Divisor This value must be an even number from 2 to 254, depending on the frequency of SSInClk . The LSB always returns 0 on reads. |

Register 6: QSSI Interrupt Mask (SSIIM), offset 0x014

The **SSIIM** register is the interrupt mask set or clear register. It is a read/write register and all bits are cleared on reset.

On a read, this register gives the current value of the mask on the corresponding interrupt. Setting a bit clears the mask, enabling the interrupt to be sent to the interrupt controller. Clearing a bit sets the corresponding mask, preventing the interrupt from being signaled to the controller.

QSSI Interrupt Mask (SSIIM)

21 Inter-Integrated Circuit (I²C) Interface

The Inter-Integrated Circuit (I²C) bus provides bi-directional data transfer through a two-wire design (a serial data line SDA and a serial clock line SCL), and interfaces to external I²C devices such as serial memory (RAMs and ROMs), networking devices, LCDs, tone generators, and so on. The I²C bus may also be used for system testing and diagnostic purposes in product development and manufacturing. The TM4C129XKCZAD microcontroller includes providing the ability to communicate (both transmit and receive) with other I²C devices on the bus.

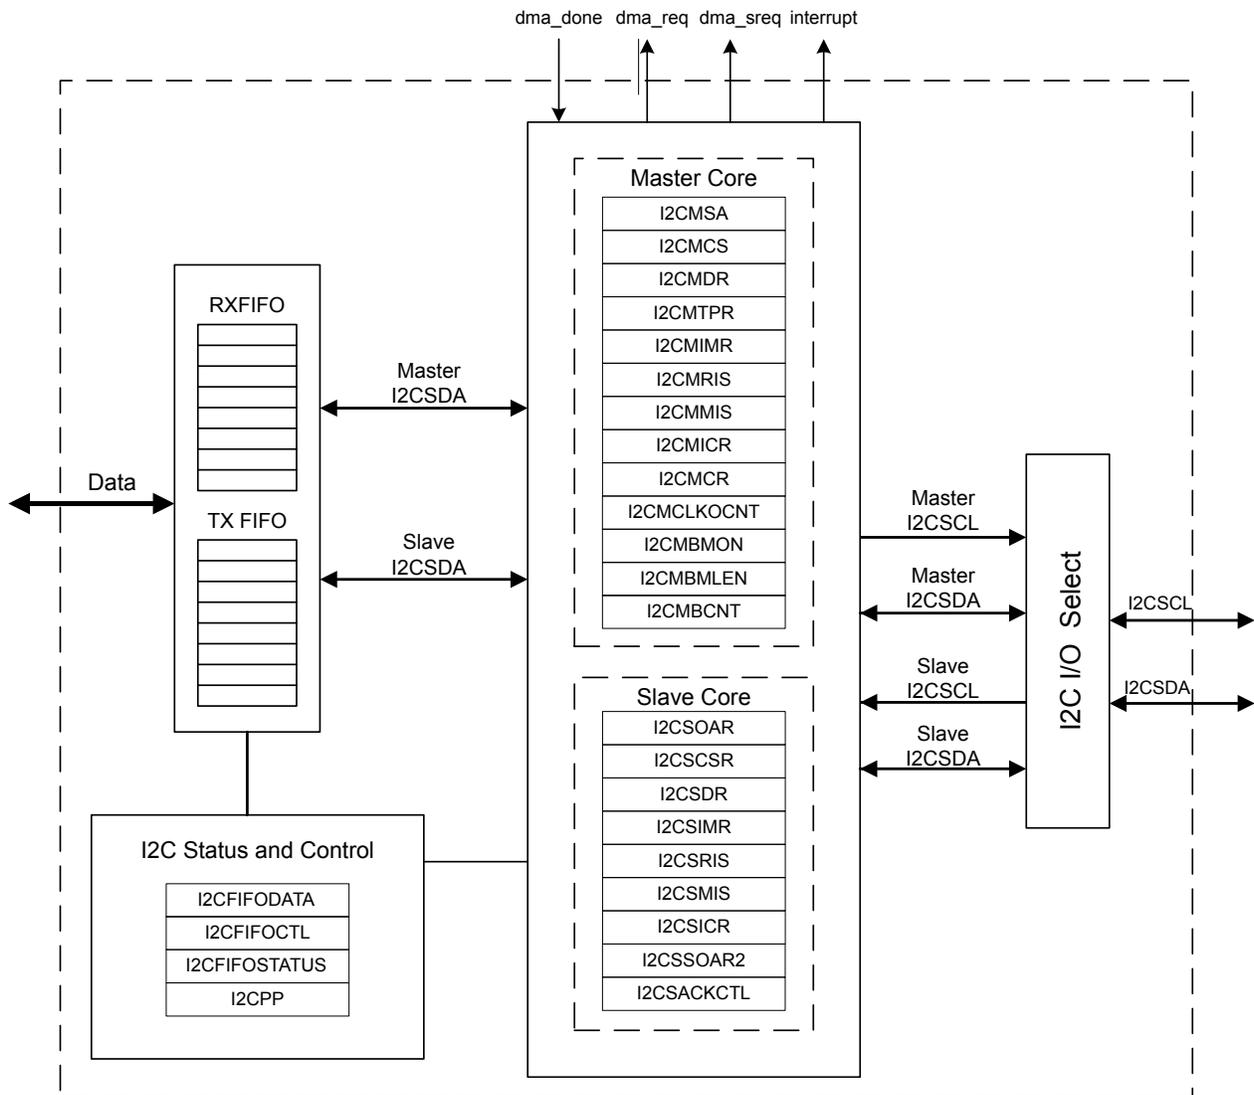

The TM4C129XKCZAD controller includes I²C modules with the following features:

- Devices on the I²C bus can be designated as either a master or a slave
 - Supports both transmitting and receiving data as either a master or a slave
 - Supports simultaneous master and slave operation
- Four I²C modes
 - Master transmit
 - Master receive
 - Slave transmit
 - Slave receive
- Two 8-entry FIFOs for receive and transmit data
 - FIFOs can be independently assigned to master or slave
- Four transmission speeds:
 - Standard (100 Kbps)
 - Fast-mode (400 Kbps)
 - Fast-mode plus (1 Mbps)
 - High-speed mode (3.33 Mbps)
- Glitch suppression
- SMBus support through software
 - Clock low timeout interrupt
 - Dual slave address capability
 - Quick command capability
- Master and slave interrupt generation
 - Master generates interrupts when a transmit or receive operation completes (or aborts due to an error)

- Slave generates interrupts when data has been transferred or requested by a master or when a START or STOP condition is detected
- Master with arbitration and clock synchronization, multimaster support, and 7-bit addressing mode
- Efficient transfers using Micro Direct Memory Access Controller (μDMA)
- Separate channels for transmit and receive
- Ability to execute single data transfers or burst data transfers using the RX and TX FIFOs in the I²C

21.1 Block Diagram

Figure 21-1. I²C Block Diagram

21.2 Signal Description

The following table lists the external signals of the I²C interface and describes the function of each. The I²C interface signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for the I²C signals. The **AFSEL** bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 803) should be set to choose the I²C function. The number in parentheses is the encoding that must be programmed into the **PMC_n** field in the **GPIO Port Control (GPIOPTL)** register (page 820) to assign the I²C signal to the specified GPIO port pin. Note that the **I2CSDA** pin should be set to open drain using the **GPIO Open Drain Select (GPIOODR)** register. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 772.

Table 21-1. I2C Signals (212BGA)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description |
|----------|-------------------------------|---|----------|-------------|--|
| I2C0SCL | A17 | PB2 (2) | I/O | OD | I ² C module 0 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| I2C0SDA | B17 | PB3 (2) | I/O | OD | I ² C module 0 data. |

| I2C8SDA | U5 D1 | PA3 (2) PD3 (2) | I/O | OD | I ² C module 8 data. |
| I2C9SCL | V3 A7 | PA0 (2) PE6 (2) | I/O | OD | I ² C module 9 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| I2C9SDA | W3 B7 | PA1 (2) PE7 (2) | I/O | OD | I ² C module 9 data. |

21.3 Functional Description

Each I²C module is comprised of both master and slave functions and is identified by a unique address. A master-initiated communication generates the clock signal, SCL. For proper operation, the SDA pin must be configured as an open-drain signal. Due to the internal circuitry that supports high-speed operation, the SCL pin must not be configured as an open-drain signal, although the internal circuitry causes it to act as if it were an open drain signal. Both SDA and SCL signals must be connected to a positive supply voltage using a pull-up resistor. A typical I²C bus configuration is shown in Figure 21-2. Refer to the *I²C-bus specification and user manual* to determine the size of the pull-ups needed for proper operation.

See “Inter-Integrated Circuit (I²C) Interface” on page 2147 for I²C timing diagrams.

Figure 21-2. I²C Bus Configuration

21.3.1 I²C Bus Functional Overview

The I²C bus uses only two signals: SDA and SCL, named I2CSDA and I2CSCL on TM4C129XKCZAD microcontrollers. SDA is the bi-directional serial data line and SCL is the bi-directional serial clock line. The bus is considered idle when both lines are High.

Every transaction on the I²C bus is nine bits long, consisting of eight data bits and a single acknowledge bit. The number of bytes per transfer (defined as the time between a valid START and STOP condition, described in “START and STOP Conditions” on page 1431) is unrestricted, but each data byte has to be followed by an acknowledge bit, and data must be transferred MSB first. When a receiver cannot receive another complete byte, it can hold the clock line SCL Low and force the transmitter into a wait state. The data transfer continues when the receiver releases the clock SCL.

21.3.1.1 START and STOP Conditions

The protocol of the I²C bus defines two states to begin and end a transaction: START and STOP. A High-to-Low transition on the SDA line while the SCL is High is defined as a START condition, and a Low-to-High transition on the SDA line while SCL is High is defined as a STOP condition. The bus is considered busy after a START condition and free after a STOP condition. See Figure 21-3.

Figure 21-3. START and STOP Conditions

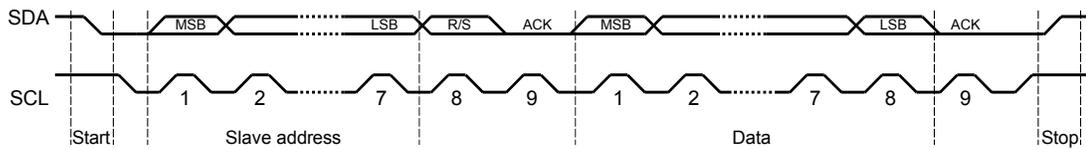

The STOP bit determines if the cycle stops at the end of the data cycle or continues on to a repeated START condition. To generate a single transmit cycle, the **I²C Master Slave Address (I2CMSA)** register is written with the desired address, the R/S bit is cleared, and the Control register is written with ACK=X (0 or 1), STOP=1, START=1, and RUN=1 to perform the operation and stop. When the operation is completed (or aborted due to an error), the interrupt pin becomes active and the data may be read from the **I²C Master Data (I2CMDR)** register. When the I²C module operates in Master receiver mode, the ACK bit is normally set causing the I²C bus controller to transmit an acknowledge automatically after each byte. This bit must be cleared when the I²C bus controller requires no further data to be transmitted from the slave transmitter.

When operating in slave mode, the STARTRIS and STOPRIS bits in the **I²C Slave Raw Interrupt Status (I2CSRIS)** register indicate detection of start and stop conditions on the bus and the **I²C Slave Masked Interrupt Status (I2CSMIS)** register can be configured to allow STARTRIS and STOPRIS to be promoted to controller interrupts (when interrupts are enabled).

21.3.1.2 Data Format with 7-Bit Address

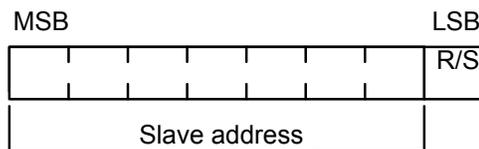

Data transfers follow the format shown in Figure 21-4. After the START condition, a slave address is transmitted. This address is 7-bits long followed by an eighth bit, which is a data direction bit (R/S bit in the I2CMSA register). If the R/S bit is clear, it indicates a transmit operation (send), and if it is set, it indicates a request for data (receive). A data transfer is always terminated by a STOP condition generated by the master, however, a master can initiate communications with another device on the bus by generating a repeated START condition and addressing another slave without first generating a STOP condition. Various combinations of receive/transmit formats are then possible within a single transfer.

Figure 21-4. Complete Data Transfer with a 7-Bit Address

The first seven bits of the first byte make up the slave address (see Figure 21-5). The eighth bit determines the direction of the message. A zero in the R/S position of the first byte means that the master transmits (sends) data to the selected slave, and a one in this position means that the master receives data from the slave.

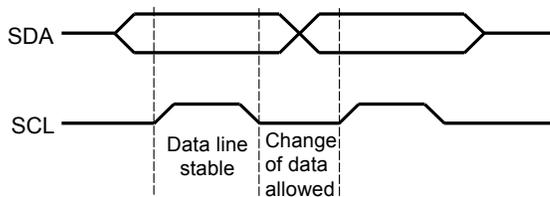

Figure 21-5. R/S Bit in First Byte

21.3.1.3 Data Validity

The data on the SDA line must be stable during the high period of the clock, and the data line can only change when SCL is Low (see Figure 21-6).

Figure 21-6. Data Validity During Bit Transfer on the I²C Bus

21.3.1.4 Acknowledge

All bus transactions have a required acknowledge clock cycle that is generated by the master. During the acknowledge cycle, the transmitter (which can be the master or slave) releases the SDA line. To acknowledge the transaction, the receiver must pull down SDA during the acknowledge clock cycle. The data transmitted out by the receiver during the acknowledge cycle must comply with the data validity requirements described in “Data Validity” on page 1432.

When a slave receiver does not acknowledge the slave address, SDA must be left High by the slave so that the master can generate a STOP condition and abort the current transfer. If the master device is acting as a receiver during a transfer, it is responsible for acknowledging each transfer made by the slave. Because the master controls the number of bytes in the transfer, it signals the end of data to the slave transmitter by not generating an acknowledge on the last data byte. The slave transmitter must then release SDA to allow the master to generate the STOP or a repeated START condition.

If the slave is required to provide a manual ACK or NACK, the **I²C Slave ACK Control (I2CSACKCTL)** register allows the slave to NACK for invalid data or command or ACK for valid data or command. When this operation is enabled, the MCU slave module I²C clock is pulled low after the last data bit until this register is written with the indicated response.

21.3.1.5 Repeated Start

The I²C master module has the capability of executing a repeated START (transmit or receive) after an initial transfer has occurred.

A repeated start sequence for a Master transmit is as follows:

1. When the device is in the idle state, the Master writes the slave address to the **I2CMSA** register and configures the R/S bit for the desired transfer type.
2. Data is written to the **I2CMDR** register.
3. When the **BUSY** bit in the **I2CMCS** register is 0, the Master writes 0x3 to the **I2CMCS** register to initiate a transfer.
4. The Master does not generate a STOP condition but instead writes another slave address to the **I2CMSA** register and then writes 0x3 to initiate the repeated START.

A repeated start sequence for a Master receive is similar:

1. When the device is in idle, the Master writes the slave address to the **I2CMSA** register and configures the R/S bit for the desired transfer type.
2. The master reads data from the **I2CMDR** register.
3. When the **BUSY** bit in the **I2CMCS** register is 0, the Master writes 0x3 to the **I2CMCS** register to initiate a transfer.
4. The Master does not generate a STOP condition but instead writes another slave address to the **I2CMSA** register and then writes 0x3 to initiate the repeated START.

For more information on repeated START, refer to Figure 21-12 on page 1446 and Figure 21-13 on page 1447.

21.3.1.6 Clock Low Timeout (CLTO)

The I²C slave can extend the transaction by pulling the clock low periodically to create a slow bit transfer rate. The I²C module has a 12-bit programmable counter that is used to track how long the clock has been held low. The upper 8 bits of the count value are software programmable through the **I²C Master Clock Low Timeout Count (I2CMCLKOCNT)** register. The lower four bits are not user visible and are 0x0. The **CNTL** value programmed in the **I2CMCLKOCNT** register has to be greater than 0x01. The application can program the eight most significant bits of the counter to reflect the acceptable cumulative low period in transaction. The count is loaded at the START condition and counts down on each falling edge of the internal bus clock of the Master. Note that the internal bus clock generated for this counter keeps running at the programmed I²C speed even if SCL is held low on the bus. Upon reaching terminal count, the master state machine forces ABORT on the bus by issuing a STOP condition at the instance of SCL and SDA release.

As an example, if an I²C module was operating at 100 kHz speed, programming the **I2CMCLKOCNT** register to 0xDA would translate to the value 0xDA0 since the lower four bits are set to 0x0. This would translate to a decimal value of 3488 clocks or a cumulative clock low period of 34.88 ms at 100 kHz.

The **CLKRIS** bit in the **I²C Master Raw Interrupt Status (I2CMRIS)** register is set when the clock timeout period is reached, allowing the master to start corrective action to resolve the remote slave state. In addition, the **CLKTO** bit in the **I²C Master Control/Status (I2CMCS)** register is set; this bit

is cleared when a STOP condition is sent or during the I²C master reset. The status of the raw SDA and SCL signals are readable by software through the *SDA* and *SCL* bits in the **I²C Master Bus Monitor (I2CMBMON)** register to help determine the state of the remote slave.

In the event of a CLTO condition, application software must choose how it intends to attempt bus recovery. Most applications may attempt to manually toggle the I²C pins to force the slave to let go of the clock signal (a common solution is to attempt to force a STOP on the bus). If a CLTO is detected before the end of a burst transfer, and the bus is successfully recovered by the master, the master hardware attempts to finish the pending burst operation. Depending on the state of the slave after bus recovery, the actual behavior on the bus varies. If the slave resumes in a state where it can acknowledge the master (essentially, where it was before the bus hang), it continues where it left off. However, if the slave resumes in a reset state (or if a forced STOP by the master causes the slave to enter the idle state), it may ignore the master's attempt to complete the burst operation and NAK the first data byte that the master sends or requests.

Since the behavior of slaves cannot always be predicted, it is suggested that the application software always write the *STOP* bit in the **I²C Master Configuration (I2CMCR)** register during the CLTO interrupt service routine. This limits the amount of data the master attempts to send or receive upon bus recovery to a single byte, and after the single byte is on the wire, the master issues a STOP. An alternative solution is to have the application software reset the I²C peripheral before attempting to manually recover the bus. This solution allows the I²C master hardware to be returned to a known good (and idle) state before attempting to recover a stuck bus and prevents any unwanted data from appearing on the wire.

Note: The Master Clock Low Timeout counter counts for the entire time *SCL* is held Low continuously. If *SCL* is deasserted at any point, the Master Clock Low Timeout Counter is reloaded with the value in the **I2CMCLKOCNT** register and begins counting down from this value.

21.3.1.7 Dual Address

The I²C interface supports dual address capability for the slave. The additional programmable address is provided and can be matched if enabled. In legacy mode with dual address disabled, the I²C slave provides an ACK on the bus if the address matches the *OAR* field in the **I2CSOAR** register. In dual address mode, the I²C slave provides an ACK on the bus if either the *OAR* field in the **I2CSOAR** register or the *OAR2* field in the **I2CSOAR2** register is matched. The enable for dual address is programmable through the *OAR2EN* bit in the **I2CSOAR2** register and there is no disable on the legacy address.

The *OAR2SEL* bit in the **I2CSCSR** register indicates if the address that was ACKed is the alternate address or not. When this bit is clear, it indicates either legacy operation or no address match.

21.3.1.8 Arbitration

A master may start a transfer only if the bus is idle. It's possible for two or more masters to generate a START condition within minimum hold time of the START condition. In these situations, an arbitration scheme takes place on the SDA line, while SCL is High. During arbitration, the first of the competing master devices to place a 1 (High) on SDA, while another master transmits a 0 (Low), switches off its data output stage and retires until the bus is idle again.

Arbitration can take place over several bits. Its first stage is a comparison of address bits, and if both masters are trying to address the same device, arbitration continues on to the comparison of data bits.

If arbitration is lost when the I²C master is initiating a BURST with the TX FIFO enabled, the application should execute the following steps to correctly handle the arbitration loss:

1. Flush and disable the TX FIFO
2. Clear and mask the TXFE interrupt by clearing the TXFEIM bit in the **I2CMIMR** register.

Once the bus is IDLE, the TXFIFO can be filled and enabled, the TXFE bit can be unmasked and a new BURST transaction can be initiated.

21.3.1.9 Glitch Suppression in Multi-Master Configuration

When a multi-master configuration is being used, the PULSESEL bit in the **I2CMTPR** register can be programmed to provide glitch suppression on the SCL and SDA lines and assure proper signal values. The glitch suppression value is in terms of buffered system clocks. Note that all signals will be delayed internally when glitch suppression is nonzero. For example, if PULSESEL is set to 0x7, 31 clocks should be added onto the calculation for the expected transaction time.

21.3.1.10 SMBus Operation

The SMBus interface is based on the I²C protocol; however, some differences exist between the two. These differences must be handled through software in order to make sure the SMBus protocol, including timing specifications, is met. Note that the SMBus 2.0 specification limits the maximum frequency of the interface to 100 KHz, as a result, I²C Standard speed operation is used for SMBus.

The SMBus/ I²C slave can extend the transaction if it is not ready by pulling the clock low. The SMBus specification allows the maximum timeout for such elongated transaction to be between 25 to 35 ms. The I²C specification does not have this requirement. The I²C module supports a programmable count to support clock-low timeout for the master to error out and take appropriate action as required. This feature is explained in "Clock Low Timeout (CLTO)" on page 1433. Note that if transactions are extended, a timeout period should be programmed in the **I2CMCLKOCNT** register, and the CLKRIS bit in the **I2CMRIS** register should not be masked.

Unlike the I²C slave, the SMBus slave must respond with an ACK response to its address regardless of whether it is ready or not. As a result, the I²C slave sends an ACK response to its address and a NACK response on the data byte if it is not ready. The ARBLST bit in the **I2CMCS** register is set if there were any issues with the transfer. In addition, the slave can send a NACK at any time to force the master to stop sending additional bytes.

The I²C Interface supports μ DMA for efficient data handling. The μ DMA operation needs FIFOs to be enabled for appropriate transfer type to perform I²C Master for burst transfers and all types of Slave transfers. The I²C interface is supported by two channels, one for Rx (I²C to Memory) and one for Tx (Memory to I²C) transfers.. See "FIFO and μ DMA Operation" on page 1439 for more information.

Quick Command

Quick Command is a simple, compact SMBus protocol that sends an address and 1-bit of data in the R/S bit of the I²C header byte to communicate a command to the slave, typically a "turn off" or "turn on". The I²C master peripheral has the ability to send a Quick Command by writing the target address and R/S value into the **I2CMSA** register followed by a write to **I2CMCS** with a value of 0x27. SMBus requires the slave to be able to accept and process commands and the master to generate the Quick Command transactions. The master also has the capability to stop the transaction after acknowledgement from a slave.

The I²C slave peripheral requires special handling when a Quick Command is sent. In the case where a master sends a Quick Command with the R/S (data) bit cleared, the QCMDST bit in **I2CSCSR** is set, and the QCMDRW bit shows the data value (which in this case is 0) when the STOPRIS bit is set in **I2CSRIS** and the STOP interrupt is asserted. In this scenario, a DATARIS interrupt bit is not

set. When the master sends a Quick Command with the R/S (data) bit set, the DATARIS bit is set to notify the slave to write a data byte to **I2CSDR** in which bit 7 is set. A “dummy write” of 0xFF to the **I2CSDR** register is recommended. After the write to **I2CSDR**, the STOP interrupt is asserted and the QCMDST and QCMDRW bits are set in the **I2CSCSR** register to indicate that a quick command read occurred and the last transaction was a Quick Command. Therefore, when the slave must receive a Quick Command, it should be expecting such a command because it must write the **I2CSDR** with a specific value when R/S is set.

21.3.2 Available Speed Modes

The I²C bus can run in Standard mode (100 kbps), Fast mode (400 kbps), Fast mode plus (1 Mbps) or High-Speed mode (3.4 Mbps, provided correct system clock frequency is set and there is appropriate pull strength on SCL and SDA lines). The selected mode should match the speed of the other I²C devices on the bus.

21.3.2.1 Standard, Fast, and Fast Plus Modes

Standard, Fast, and Fast Plus modes are selected using a value in the **I²C Master Timer Period (I2CMTPR)** register that results in an SCL frequency of 100 kbps for Standard mode, 400 kbps for Fast mode, or 1 Mbps for Fast mode plus.

The I²C clock rate is determined by the parameters *CLK_PRD*, *TIMER_PRD*, *SCL_LP*, and *SCL_HP* where:

CLK_PRD is the system clock period

SCL_LP is the low phase of SCL (fixed at 6)

SCL_HP is the high phase of SCL (fixed at 4)

TIMER_PRD is the programmed value in the **I2CMTPR** register (see page 1465). This value is determined by replacing the known variables in the equation below and solving for *TIMER_PRD*.

The I²C clock period is calculated as follows:

$$SCL_PERIOD = 2 \times (1 + TIMER_PRD) \times (SCL_LP + SCL_HP) \times CLK_PRD$$

For example:

$$CLK_PRD = 50 \text{ ns}$$

$$TIMER_PRD = 2$$

$$SCL_LP = 6$$

$$SCL_HP = 4$$

yields a SCL frequency of:

$$1/SCL_PERIOD = 333 \text{ Khz}$$

Table 21-2 gives examples of the timer periods that should be used to generate Standard, Fast mode, and Fast mode plus SCL frequencies based on various system clock frequencies.

Table 21-2. Examples of I²C Master Timer Period Versus Speed Mode

| System Clock | Timer Period | Standard Mode | Timer Period | Fast Mode | Timer Period | Fast Mode Plus |
|--------------|--------------|---------------|--------------|-----------|--------------|----------------|
| 4 MHz | 0x01 | 100 Kbps | - | - | - | - |
| 6 MHz | 0x02 | 100 Kbps | - | - | - | - |

Table 21-2. Examples of I²C Master Timer Period Versus Speed Mode (continued)

| System Clock | Timer Period | Standard Mode | Timer Period | Fast Mode | Timer Period | Fast Mode Plus |
|--------------|--------------|---------------|--------------|-----------|--------------|----------------|
| 12.5 MHz | 0x06 | 89 Kbps | 0x01 | 312 Kbps | - | - |
| 16.7 MHz | 0x08 | 93 Kbps | 0x02 | 278 Kbps | - | - |
| 20 MHz | 0x09 | 100 Kbps | 0x02 | 333 Kbps | - | - |
| 25 MHz | 0x0C | 96.2 Kbps | 0x03 | 312 Kbps | - | - |
| 33 MHz | 0x10 | 97.1 Kbps | 0x04 | 330 Kbps | - | - |
| 40 MHz | 0x13 | 100 Kbps | 0x04 | 400 Kbps | 0x01 | 1000 Kbps |
| 50 MHz | 0x18 | 100 Kbps | 0x06 | 357 Kbps | 0x02 | 833 Kbps |
| 80 MHz | 0x27 | 100 Kbps | 0x09 | 400 Kbps | 0x03 | 1000 Kbps |
| 100 MHz | 0x31 | 100 Kbps | 0x0C | 385 Kbps | 0x04 | 1000 Kbps |
| 120 MHz | 0x3B | 100 Kbps | 0xE | 400 Kbps | 0x5 | 1000 Kbps |

21.3.2.2 High-Speed Mode

The TM4C129XKCZAD I²C peripheral has support for High-speed operation as both a master and slave. High-Speed mode is configured by setting the HS bit in the **I²C Master Control/Status (I2CMCS)** register. High-Speed mode transmits data at a high bit rate with a 66.6%/33.3% duty cycle, but communication and arbitration are done at Standard, Fast mode, or Fast-mode plus speed, depending on which is selected by the user. When the HS bit in the **I2CMCS** register is set, current mode pull-ups are enabled.

The clock period can be selected using the equation below, but in this case, SCL_LP=2 and SCL_HP=1.

$$SCL_PERIOD = 2 \times (1 + TIMER_PRD) \times (SCL_LP + SCL_HP) \times CLK_PRD$$

So for example:

$$CLK_PRD = 25 \text{ ns}$$

$$TIMER_PRD = 1$$

$$SCL_LP=2$$

$$SCL_HP=1$$

yields a SCL frequency of:

$$1/T = 3.33 \text{ Mhz}$$

Table 21-3 on page 1437 gives examples of timer period and system clock in High-Speed mode. Note that the HS bit in the **I2CMTPR** register needs to be set for the TPR value to be used in High-Speed mode.

Table 21-3. Examples of I²C Master Timer Period in High-Speed Mode

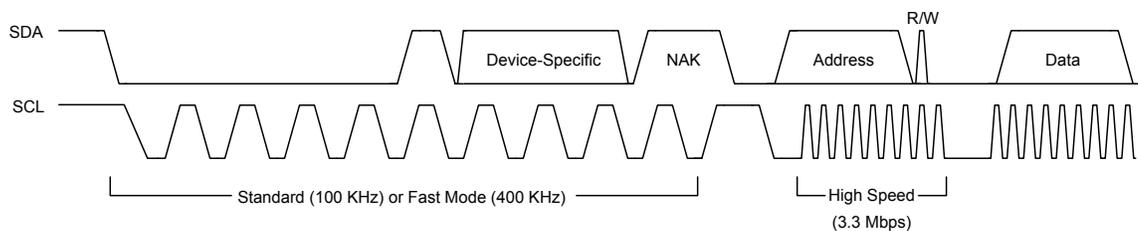

| System Clock | Timer Period | Transmission Mode |
|--------------|--------------|-------------------|
| 40 MHz | 0x01 | 3.33 Mbps |
| 50 MHz | 0x02 | 2.77 Mbps |
| 80 MHz | 0x03 | 3.33 Mbps |

When operating as a master, the protocol is shown in Figure 21-7. The master is responsible for sending a master code byte in either Standard (100 Kbps) or Fast-mode (400 Kbps) before it begins

transferring in High-speed mode. The master code byte must contain data in the form of 0000.1XXX and is used to tell the slave devices to prepare for a High-speed transfer. The master code byte should never be acknowledged by a slave since it is only used to indicate that the upcoming data is going to be transferred at a higher data rate. To send the master code byte for a standard high-speed transfer, software should place the value of the master code byte into the **I2CMSA** register and write the **I2CMCS** register with a value of 0x13. If a high-speed burst transfer is required, then to send the master code byte, software should place the value of the master code byte into the **I2CMSA** register and write the **I2CMCS** register with 0x50. Either configuration places the I²C master peripheral in High-speed mode, and all subsequent transfers (until STOP) are carried out at High-speed data rate using the normal **I2CMCS** command bits, without setting the HS bit in the **I2CMCS** register. Again, setting the HS bit in the **I2CMCS** register is only necessary during the master code byte.

When operating as a High-speed slave, there is no additional software required.

Figure 21-7. High-Speed Data Format

Note: High-Speed mode is 3.4 Mbps, provided correct system clock frequency is set and there is appropriate pull strength on SCL and SDA lines.

21.3.3 Interrupts

The I²C can generate interrupts when the following conditions are observed in the Master Module:

- Master transaction completed (RIS bit)
- Master arbitration lost (ARBLOSTRIS bit)
- Master Address/Data NACK (NACKRIS bit)
- Master bus timeout (CLKRIS bit)
- Next byte request (RIS bit)
- Stop condition on bus detected (STOPRIS bit)
- Start condition on bus detected (STARTRIS bit)
- RX DMA interrupt pending (DMARXRIS bit)
- TX DMA interrupt pending (DMATXRIS bit)
- Trigger value for FIFO has been reached and a TX FIFO request interrupt is pending (TXRIS bit)
- Trigger value for FIFO has been reached and a RX FIFO request interrupt is pending (RXRIS bit)

- Transmit FIFO is empty (TXFERIS bit)
- Receive FIFO is full (RXFFRIS bit)

Interrupts are generated when the following conditions are observed in the Slave Module:

- Slave transaction received (DATARIS bit)
- Slave transaction requested (DATARIS bit)
- Slave next byte transfer request (DATARIS bit)
- Stop condition on bus detected (STOPRIS bit)
- Start condition on bus detected (STARTRIS bit)
- RX DMA interrupt pending (DMARXRIS bit)
- TX DMA interrupt pending (DMATXRIS bit)
- Programmable trigger value for FIFO has been reached and a TX FIFO request interrupt is pending (TXRIS bit)
- Programmable trigger value for FIFO has been reached and a RX FIFO request interrupt is pending (RXRIS bit)
- Transmit FIFO is empty (TXFERIS bit)
- Receive FIFO is full (RXFFRIS bit)

The I²C master and I²C slave modules have separate interrupt registers. Interrupts can be masked by clearing the appropriate bit in the **I2CMIMR** or **I2CSIMR** register. Note that the RIS bit in the **Master Raw Interrupt Status (I2CMRIS)** register and the DATARIS bit in the **Slave Raw Interrupt Status (I2CSRIS)** register have multiple interrupt causes including a next byte transfer request interrupt. This interrupt is generated when both master and slave are requesting a receive or transmit transaction.

21.3.4 Loopback Operation

The I²C modules can be placed into an internal loopback mode for diagnostic or debug work by setting the LPBK bit in the **I²C Master Configuration (I2CMCR)** register. In loopback mode, the SDA and SCL signals from the master and are tied to the SDA and SCL signals of the slave module to allow internal testing of the device without having to go through I/O.

21.3.5 FIFO and μ DMA Operation

Both the master and the slave module have the capability to access two 8-byte FIFOs that can be used in conjunction with the μ DMA for fast transfer of data. The transmit (TX) FIFO and receive (RX) FIFO can be independently assigned to either the I²C master or I²C slave. Thus, the following FIFO assignments are allowed:

- The transmit and receive FIFOs can be assigned to the master
- The transmit and receive FIFOs can be assigned to the slave

- The transmit FIFO can be assigned to the master, while the receive FIFO is assigned to the slave and vice versa.

In most cases, both FIFOs will be assigned to either the master or the slave. The FIFO assignment is configured by programming the `TXASGNMT` and `RXASGNMT` bit in the **I²C FIFO Control (I2CFIFOCTL)** register.

Each FIFO has a programmable threshold point which indicates when the FIFO service interrupt should be generated. Additionally, a FIFO receive full and transmit empty interrupt can be enabled in the Interrupt Mask (**I2CxIMR**) registers of both the master and slave. Note that if we clear the `TXFERIS` interrupt (by setting the `TXFEIC` bit) when the TX FIFO is empty, the `TXFERIS` interrupt does not reassert even though the TX FIFO remains empty in this situation.

When a FIFO is not assigned to a master or a slave module, the FIFO interrupt and status signals to the module are forced to a state that indicates the FIFO is empty. For example, if the TX FIFO is assigned to the master module, the status signals to the slave transmit interface indicates that the FIFO is empty.

Note: The FIFOs must be empty when reassigning the FIFOs for proper functionality

21.3.5.1 Master Module Burst Mode

A BURST command is provided for the master module which allows a sequence of data transfers using the μ DMA (or software, if desired) to handle the data in the FIFO. The BURST command is enabled by setting the BURST bit in the **Master Control/Status (I2CMCS)** register. The number of bytes transferred by a BURST request is programmed in the **I2C Master Burst Length (I2CMBLEN)** register and a copy of this value is automatically written to the **I2C Master Burst Count (I2CMBCNT)** register to be used as a down-counter during the BURST transfer. The bytes written to the **I2C FIFO Data (I2CFIFODATA)** register are transferred to the RX FIFO or TX FIFO depending on whether a transmit or receive is being executed. If data is NACKed during a BURST and the `STOP` bit is set in the **I2CMCS** register, the transfer terminates. If the `STOP` bit is not set, the software application must issue a repeated `STOP` or `START` when a NACK interrupt is asserted. In the case of a NACK, the **I2CMBCNT** register can be used to determine the amount of data that was transferred prior to the BURST termination. If the Address is NACKed during a transfer, then a `STOP` is issued.

Master Module μ DMA Functionality

When the **Master Control/Status (I2CMCS)** register is set to enable BURST and the master I²C μ DMA channel is enabled in the **DMA Channel Map Select n (DMACHMAPn)** registers in the μ DMA, the master control module will assert either the internal single μ DMA request signal (`dma_sreq`) or multiple μ DMA request signal (`dma_req`) to the μ DMA. Note that there are separate `dma_req` and `dma_sreq` signals for transmit and receive. A single μ DMA request (`dma_sreq`) will be asserted by the Master module when the Rx FIFO has at least one data byte present in the FIFO and/or when the Tx FIFO has at least one space available to fill. The `dma_req` (or Burst) signal will be asserted when Rx FIFO fill level is higher than trigger level and/or the Tx FIFO burst length remaining is less than 4 bytes and the FIFO fill level is less than trigger level. If a single transfer or BURST operation has completed, the μ DMA sends a `dma_done` signal to the master module represented by the `DMATX/DMARX` interrupts in the **I2CMIMR/I2CMRIS/I2CMMIS/I2CMICR** registers.

If the μ DMA I²C channel is disabled and software is used to handle the BURST command, software can read the **FIFO Status (I2CFIFOSTAT)** Register and the **Master Burst Count (I2CMBC)** register to determine whether the FIFO needs servicing during the BURST transaction. A trigger value can be programmed in the **I2CFIFOCTL** register to allow for interrupts at various fill levels of the FIFOs.

The `NACK` and `ARBLOST` bits in the interrupt status registers can be enabled to indicate no acknowledgement of data transfer or an arbitration loss on the bus.

When the Master module is transmitting FIFO data, software can fill the Tx FIFO in advance of setting the BURST bit in the **I2CMCS** register. If the FIFO is empty when the μ DMA is enabled for BURST mode, the `dma_req` and `dma_sreq` both assert (assuming the **I2CMLEN** register is programmed to at least 4 bytes and the Tx FIFO fill level is less than the trigger set). If the **I2CMLEN** register value is less than 4 and the Tx FIFO is not full but more than trigger level, only `dma_sreq` will assert. Single requests will be generated as required to keep the FIFO full until the number of bytes specified in the **I2CMLEN** register has been transferred to the FIFO (and the **I2CMBCOUNT** register reaches 0x0). At this point, no further requests are generated until the next BURST command is issued. If the μ DMA is disabled, FIFOs will be serviced based on the interrupts active in the Master interrupt status registers, the FIFO trigger values shown in the **I2CFIFOSTATUS** register and completion of a BURST transfer.

When the Master module is receiving FIFO data, the Rx FIFO is initially empty and no requests are asserted. If data is read from the slave and placed into the Rx FIFO, the `dma_sreq` signal to the μ DMA is asserted to indicate there is data to be transferred. If the Rx FIFO contains at least 4 bytes, the `dma_req` signal is also asserted. The μ DMA will continue to transfer data out of the Rx FIFO until it has reached the amount of bytes programmed in the **I2CMLEN** register.

Note: The **TXFEIM** interrupt mask bit in the **I2CMIMR** register should be clear (masking the **TXFE** interrupt) when the master is performing an RX Burst from the RXFIFO and should be unmasked before starting a TX FIFO transfers.

21.3.5.2 Slave Module

The slave module also has the capability to use the μ DMA in Rx and Tx FIFO data transfers. If the Tx FIFO is assigned to the slave module and the **TXFIFO** bit is set in the **I2CCSR** register, the slave module will generate a single μ DMA request, `dma_sreq`, if the master module requests the next byte transfer. If the FIFO fill level is less than the trigger level, a μ DMA multiple transfer request, `dma_req`, will be asserted to continue data transfers from the μ DMA.

If the Rx FIFO is assigned to the slave module and the **RXFIFO** bit is set in the **I2CCSR** register, then the slave module will generate a signal μ DMA request, `dma_sreq`, if there is any data to be transferred. The `dma_req` signal will be asserted when the Rx FIFO has more data than the trigger level programmed by the **RXTRIG** bit in the **I2CFIFOCTL** register.

Note: Best practice recommends that an application should not switch between the **I2CSDR** register and TX FIFO or vice versa for successive transactions.

21.3.6 Command Sequence Flow Charts

This section details the steps required to perform the various I²C transfer types in both master and slave mode. Refer to Table 21-5 on page 1460 for further sequence information.

21.3.6.1 I²C Master Command Sequences

The figures that follow show the command sequences available for the I²C master.

21.3.6.2 I²C Slave Command Sequences

Figure 21-15 on page 1449 presents the command sequence available for the I²C slave.

Figure 21-15. Slave Command Sequence

21.4 Initialization and Configuration

21.4.1 Configure the I²C Module to Transmit a Single Byte as a Master

The following example shows how to configure the I²C module to transmit a single byte as a master. This assumes the system clock is 20 MHz.

1. Enable the I²C clock using the **RCGCI2C** register in the System Control module (see page 408).
2. Enable the clock to the appropriate GPIO module via the **RCGCGPIO** register in the System Control module (see page 399). To find out which GPIO port to enable, refer to Table 31-5 on page 2081.
3. In the GPIO module, enable the appropriate pins for their alternate function using the **GPIOAFSEL** register (see page 803). To determine which GPIOs to configure, see Table 31-4 on page 2064.

4. Enable the I²CSDA pin for open-drain operation. See page 808.
5. Configure the PMCN fields in the GPIOCTL register to assign the I²C signals to the appropriate pins. See page 820 and Table 31-5 on page 2081.
6. Initialize the I²C Master by writing the I2CMCR register with a value of 0x0000.0010.
7. Set the desired SCL clock speed of 100 Kbps by writing the I2CMTPR register with the correct value. The value written to the I2CMTPR register represents the number of system clock periods in one SCL clock period. The TPR value is determined by the following equation:

$$\begin{aligned} \text{TPR} &= (\text{System Clock} / (2 * (\text{SCL_LP} + \text{SCL_HP}) * \text{SCL_CLK})) - 1; \\ \text{TPR} &= (20\text{MHz} / (2 * (6+4) * 100000)) - 1; \\ \text{TPR} &= 9 \end{aligned}$$

Write the I2CMTPR register with the value of 0x0000.0009.

8. Specify the slave address of the master and that the next operation is a Transmit by writing the I2CMSA register with a value of 0x0000.0076. This sets the slave address to 0x3B.
9. Place data (byte) to be transmitted in the data register by writing the I2CMDR register with the desired data.
10. Initiate a single byte transmit of the data from Master to Slave by writing the I2CMCS register with a value of 0x0000.0007 (STOP, START, RUN).
11. Wait until the transmission completes by polling the I2CMCS register's BUSBSY bit until it has been cleared.
12. Check the ERROR bit in the I2CMCS register to confirm the transmit was acknowledged.

21.4.2 Configure the I²C Master to High Speed Mode

To configure the I²C master to High Speed mode:

1. Enable the I²C clock using the RCGCI2C register in the System Control module (see page 408).
2. Enable the clock to the appropriate GPIO module via the RCGCGPIO register in the System Control module (see page 399). To find out which GPIO port to enable, refer to Table 31-5 on page 2081.
3. In the GPIO module, enable the appropriate pins for their alternate function using the GPIOAFSEL register (see page 803). To determine which GPIOs to configure, see Table 31-4 on page 2064.
4. Enable the I²CSDA pin for open-drain operation. See page 808.
5. Configure the PMCN fields in the GPIOCTL register to assign the I²C signals to the appropriate pins. See page 820 and Table 31-5 on page 2081.
6. Initialize the I²C Master by writing the I2CMCR register with a value of 0x0000.0010.
7. Set the desired SCL clock speed of 3.33 Mbps by writing the I2CMTPR register with the correct value. The value written to the I2CMTPR register represents the number of system clock periods in one SCL clock period. The TPR value is determined by the following equation:

```

TPR = (System Clock / (2 * (SCL_LP + SCL_HP) * SCL_CLK)) - 1;
TPR = (80 MHz / (2 * (2 + 1) * 3330000)) - 1;
TPR = 3

```

Write the **I2CMTPR** register with the value of 0x0000.0003.

8. To send the master code byte, software should place the value of the master code byte into the I2CMSA register and write the I2CMCS register with the following value depending on the required operation:
 - For Standard High-Speed mode, the **I2CMCS** register should be written with 0x13.
 - For Burst High-Speed mode, the **I2CMCS** register should be written with 0x50.
9. This places the I2C master peripheral in High-speed mode, and all subsequent transfers (until STOP) are carried out at High-speed data rate using the normal **I2CMCS** command bits, without setting the HS bit in the **I2CMCS** register.
10. The transaction is ended by setting the STOP bit in the **I2CMCS** register.
11. Wait until the transmission completes by polling the **I2CMCS** register's BUSBSY bit until it has been cleared.
12. Check the ERROR bit in the **I2CMCS** register to confirm the transmit was acknowledged.

21.5 Register Map

Table 21-4 on page 1452 lists the I²C registers. All addresses given are relative to the I²C base address:

- I²C 0: 0x4002.0000
- I²C 1: 0x4002.1000
- I²C 2: 0x4002.2000
- I²C 3: 0x4002.3000
- I²C 4: 0x400C.0000
- I²C 5: 0x400C.1000
- I²C 6: 0x400C.2000
- I²C 7: 0x400C.3000
- I²C 8: 0x400B.8000
- I²C 9: 0x400B.9000

Note that the I²C module clock must be enabled before the registers can be programmed (see page 408). There must be a delay of 3 system clocks after the I²C module clock is enabled before any I²C module registers are accessed.

The hw_i2c.h file in the TivaWare™ Driver Library uses a base address of 0x800 for the I²C slave registers. Be aware when using registers with offsets between 0x800 and 0x818 that TivaWare™ for C Series uses an offset between 0x000 and 0x018 with the slave base address.

Table 21-4. Inter-Integrated Circuit (I²C) Interface Register Map

| Offset | Name | Type | Reset | Description | See page |
|--|---------------|------|-------------|------------------------------------|----------|

21.6 Register Descriptions (I²C Master)

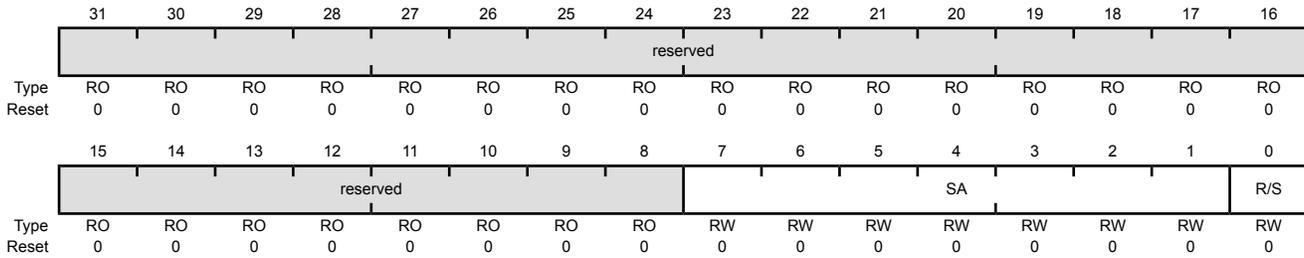

The remainder of this section lists and describes the I²C master registers, in numerical order by address offset.

Register 1: I²C Master Slave Address (I2CMSA), offset 0x000

This register consists of eight bits: seven address bits (A6-A0), and a Receive/Send bit, which determines if the next operation is a Receive (High), or Transmit (Low).

I2C Master Slave Address (I2CMSA)

I2C 0 base: 0x4002.0000
 I2C 1 base: 0x4002.1000
 I2C 2 base: 0x4002.2000
 I2C 3 base: 0x4002.3000
 I2C 4 base: 0x400C.0000
 I2C 5 base: 0x400C.1000
 I2C 6 base: 0x400C.2000
 I2C 7 base: 0x400C.3000
 I2C 8 base: 0x400B.8000
 I2C 9 base: 0x400B.9000
 Offset 0x000
 Type RW, reset 0x0000.0000

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|-----------|---|
| 31:8 | reserved | RO | 0x0000.00 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 7:1 | SA | RW | 0x00 | I ² C Slave Address This field specifies bits A6 through A0 of the slave address. |
| 0 | R/S | RW | 0 | Receive/Send The R/S bit specifies if the next master operation is a Receive (High) or Transmit (Low). Value Description 0 Transmit 1 Receive |

Register 2: I²C Master Control/Status (I2CMCS), offset 0x004

This register accesses status bits when read and control bits when written. When read, the status register indicates the state of the I²C bus controller. When written, the control register configures the I²C controller operation.

The **START** bit generates the **START** or **REPEATED START** condition. The **STOP** bit determines if the cycle stops at the end of the data cycle or continues to the next transfer cycle, which could be a repeated **START**. To generate a single transmit cycle, the **I²C Master Slave Address (I2CMSA)** register is written with the desired address, the **R/S** bit is cleared, and this register is written with **ACK=X** (0 or 1), **STOP=1**, **START=1**, and **RUN=1** to perform the operation and stop. When the operation is completed (or aborted due an error), an interrupt becomes active and the data may be read from the **I2CMDR** register. When the I²C module operates in Master receiver mode, the **ACK** bit is normally set, causing the I²C bus controller to transmit an acknowledge automatically after each byte. This bit must be cleared when the I²C bus controller requires no further data to be transmitted from the slave transmitter.

Read-Only Status Register

I2C Master Control/Status (I2CMCS)

I2C 0 base: 0x4002.0000

| | 1 | 0 | 0 | 0 | 0 | 1 | 0 | 1 | 1 | Repeated START condition followed by RECEIVE (master remains in Master Receive state). |
| | 1 | 1 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | Repeated START condition followed by N FIFO-serviced RECEIVE operations with a negative ACK on the last RECEIVE (master remains in Master Receive state). |
| | 1 | 1 | 0 | 0 | 0 | 0 | 1 | 1 | 0 | Repeated START condition followed by N FIFO-serviced RECEIVE operations and STOP condition (master goes to Idle state). |
| | 1 | 1 | 0 | 0 | 0 | 1 | 0 | 1 | 0 | Repeated START condition followed by N FIFO-serviced RECEIVE operations (master remains in Master Receive state). |
| | 0 | 0 | 0 | 0 | 0 | X | 0 | 1 | 1 | Repeated START condition followed by TRANSMIT (master goes to Master Transmit state). |
| | 0 | 0 | 0 | 0 | 0 | X | 1 | 1 | 1 | Repeated START condition followed by TRANSMIT and STOP condition (master goes to Idle state). |
| | 0 | 1 | 0 | 0 | 0 | X | 0 | 1 | 0 | Repeated START condition followed by N FIFO-serviced TRANSMIT operations (master goes to Master Transmit state). |
| | 0 | 1 | 0 | 0 | 0 | X | 1 | 1 | 0 | Repeated START condition followed by N FIFO-serviced TRANSMIT operations and STOP condition (master goes to Idle state). |
| All other combinations not listed are non-operations. | | | | | | | | | NOP. | |

a. An X in a table cell indicates the bit can be 0 or 1.

- b. In Master Receive mode, a STOP condition should be generated only after a Data Negative Acknowledge executed by the master or an Address Negative Acknowledge executed by the slave.

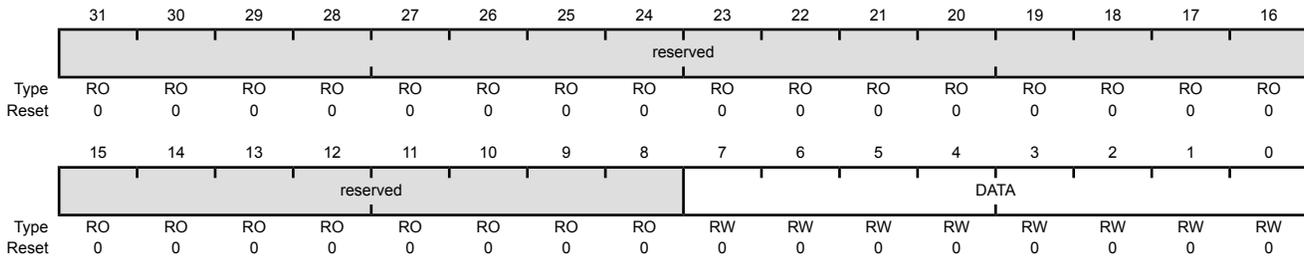

Register 3: I²C Master Data (I2CMDR), offset 0x008

Important: This register is read-sensitive. See the register description for details.

This register contains the data to be transmitted when in the Master Transmit state and the data received when in the Master Receive state. If the `BURST` bit is enabled in the `I2CMCS` register, then the `I2CFIFODATA` register is used for the current data transmit or receive value and this register is ignored.

I2C Master Data (I2CMDR)

I2C 0 base: 0x4002.0000
 I2C 1 base: 0x4002.1000
 I2C 2 base: 0x4002.2000
 I2C 3 base: 0x4002.3000
 I2C 4 base: 0x400C.0000
 I2C 5 base: 0x400C.1000
 I2C 6 base: 0x400C.2000
 I2C 7 base: 0x400C.3000
 I2C 8 base: 0x400B.8000
 I2C 9 base: 0x400B.9000
 Offset 0x008
 Type RW, reset 0x0000.0000

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|-----------|---|
| 31:8 | reserved | RO | 0x0000.00 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 7:0 | DATA | RW | 0x00 | This byte contains the data transferred during a transaction. |

Register 4: I²C Master Timer Period (I2CMTPR), offset 0x00C

This register is programmed to set the timer period for the SCL clock and assign the SCL clock to either standard or high-speed mode.

I2C Master Timer Period (I2CMTPR)

I2C 0 base: 0x4002.0000
 I2C 1 base: 0x4002.1000

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|-------|---|
| 31:12 | reserved | RO | 0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 11 | RXFFIM | RW | 0 | Receive FIFO Full Interrupt Mask Value Description 0 The RXFFRIS interrupt is suppressed and not sent to the interrupt controller. 1 The Receive FIFO Full interrupt is sent to the interrupt controller when the RXFFRIS bit in the I2CMRIS register is set. |
| 10 | TXFEIM | RW | 0 | Transmit FIFO Empty Interrupt Mask Note: The TXFEIM interrupt mask bit in the I2CMIMR register should be clear (masking the TXFE interrupt) when the master is performing an RX Burst from the RXFIFO and should be unmasked before starting a TX FIFO transfers. Value Description 0 The TXFERIS interrupt is suppressed and not sent to the interrupt controller. 1 The Transmit FIFO Empty interrupt is sent to the interrupt controller when the TXFERIS bit in the I2CMRIS register is set. |

| Bit/Field | Name | Type | Reset | Description |
|-----------|-----------|------|-------|---|
| 9 | RXIM | RW | 0 | Receive FIFO Request Interrupt Mask Value Description 0 The <code>RXRIS</code> interrupt is suppressed and not sent to the interrupt controller. 1 The RX FIFO Request interrupt is sent to the interrupt controller when the <code>RXRIS</code> bit in the I2CMRIS register is set. |
| 8 | TXIM | RW | 0 | Transmit FIFO Request Interrupt Mask Value Description 0 The <code>TXRIS</code> interrupt is suppressed and not sent to the interrupt controller. 1 The TX FIFO Request interrupt is sent to the interrupt controller when the <code>TXRIS</code> bit in the I2CMRIS register is set. |
| 7 | ARBLOSTIM | RW | 0 | Arbitration Lost Interrupt Mask Value Description 0 The <code>ARBLOSTRIS</code> interrupt is suppressed and not sent to the interrupt controller. 1 The Arbitration Lost interrupt is sent to the interrupt controller when the <code>ARBLOSTRIS</code> bit in the I2CMRIS register is set. |
| 6 | STOPIIM | RW | 0 | STOP Detection Interrupt Mask Value Description 0 The <code>STOPRIS</code> interrupt is suppressed and not sent to the interrupt controller. 1 The STOP detection interrupt is sent to the interrupt controller when the <code>STOPRIS</code> bit in the I2CMRIS register is set. |
| 5 | STARTIM | RW | 0 | START Detection Interrupt Mask Value Description 0 The <code>STARTRIS</code> interrupt is suppressed and not sent to the interrupt controller. 1 The START detection interrupt is sent to the interrupt controller when the <code>STARTRIS</code> bit in the I2CMRIS register is set. |
| 4 | NACKIM | RW | 0 | Address/Data NACK Interrupt Mask Value Description 0 The <code>NACKRIS</code> interrupt is suppressed and not sent to the interrupt controller. 1 The address/data NACK interrupt is sent to the interrupt controller when the <code>NACKRIS</code> bit in the I2CMRIS register is set. |

| Bit/Field | Name | Type | Reset | Description |
|-----------|---------|------|-------|--|
| 3 | DMATXIM | RW | 0 | Transmit DMA Interrupt Mask Value Description 0 The <code>DMATXRIS</code> interrupt is suppressed and not sent to the interrupt controller. 1 The transmit DMA complete interrupt is sent to the interrupt controller when the <code>DMATXRIS</code> bit in the I2CMRIS register is set. |
| 2 | DMARXIM | RW | 0 | Receive DMA Interrupt Mask Value Description 0 The <code>DMARXRIS</code> interrupt is suppressed and not sent to the interrupt controller. 1 The receive DMA complete interrupt is sent to the interrupt controller when the <code>DMARXRIS</code> bit in the I2CMRIS register is set. |
| 1 | CLKIM | RW | 0 | Clock Timeout Interrupt Mask Value Description 0 The <code>CLKRIS</code> interrupt is suppressed and not sent to the interrupt controller. 1 The clock timeout interrupt is sent to the interrupt controller when the <code>CLKRIS</code> bit in the I2CMRIS register is set. |
| 0 | IM | RW | 0 | Master Interrupt Mask Value Description 0 The <code>RIS</code> interrupt is suppressed and not sent to the interrupt controller. 1 The master interrupt is sent to the interrupt controller when the <code>RIS</code> bit in the I2CMRIS register is set. |

Register 6: I²C Master Raw Interrupt Status (I2CMRIS), offset 0x014

This register specifies whether an interrupt is pending.

I2C Master Raw Interrupt Status (I2CMRIS)

I2C 0 base: 0x4002.0000
 I2C 1 base: 0x4002.1000

| 0 | LPBK | RW | 0 | I ² C Loopback Value Description 0 Normal operation. 1 The controller in a test mode loopback configuration. |

Register 10: I²C Master Clock Low Timeout Count (I2CMCLKOCNT), offset 0x024

This register contains the upper 8 bits of a 12-bit counter that can be used to keep the timeout limit for clock stretching by a remote slave. The lower four bits of the counter are not user visible and are always 0x0.

Note: The Master Clock Low Timeout counter counts for the entire time `SCL` is held Low continuously. If `SCL` is deasserted at any point, the Master Clock Low Timeout Counter is reloaded with the value in the `I2CMCLKOCNT` register and begins counting down from this value.

| 31:8 | reserved | RO | 0x0000.00 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 7:0 | CNTL | RW | 0 | I ² C Burst Length This field contains the programmed length of bytes of the Burst Transaction. If BURST is enabled this register must be set to a non-zero value otherwise an error will occur. |

Register 13: I²C Master Burst Count (I2CMBCNT), offset 0x034

When BURST is active, the value in the **I2CMBLEN** register is copied into this register and decremented during the BURST transaction. This register can be used to determine the number of transfers that occurred when a BURST terminates early (as a result of a data NACK). When a BURST completes successfully, this register will contain 0.

I2C Master Burst Count (I2CMBCNT)

 I2C 8 base: 0x400B.8000
 I2C 9 base: 0x400B.9000
 Offset 0x804
 Type WO, reset 0x0000.0000

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|-------|---|
| 31:3 | reserved | RO | 0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 2 | RXFIFO | WO | 0 | RX FIFO Enable Value Description 0 Disables RX FIFO 1 Enables RX FIFO |
| 1 | TXFIFO | WO | 0 | TX FIFO Enable Value Description 0 Disables TX FIFO 1 Enables TX FIFO |
| 0 | DA | WO | 0 | Device Active Value Description 0 Disables the I ² C slave operation. 1 Enables the I ² C slave operation. Once this bit has been set, it should not be set again unless it has been cleared by writing a 0 or by a reset, otherwise transfer failures may occur. |

Register 16: I²C Slave Data (I2CSDR), offset 0x808

Important: This register is read-sensitive. See the register description for details.

This register contains the data to be transmitted when in the Slave Transmit state, and the data received when in the Slave Receive state. If the **RXFIFO** bit or **TXFIFO** bit are enabled in the **I2CCSR** register, then this register is ignored and the data value being transferred from the FIFO is contained in the **I2CFIFODATA** register.

Note: Best practice recommends that an application should not switch between the **I2CSDR** register and TX FIFO or vice versa for successive transactions.

 I2C 9 base: 0x400B.9000
 Offset 0x81C
 Type RW, reset 0x0000.0000

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|-----------|---|
| 31:8 | reserved | RO | 0x0000.00 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 7 | OAR2EN | RW | 0 | I ² C Slave Own Address 2 Enable Value Description 0 The alternate address is disabled. 1 Enables the use of the alternate address in the OAR2 field. |
| 6:0 | OAR2 | RW | 0x00 | I ² C Slave Own Address 2 This field specifies the alternate OAR2 address. |

Register 22: I²C Slave ACK Control (I2CSACKCTL), offset 0x820

This register enables the I²C slave to NACK for invalid data or command or ACK for valid data or command. The I²C clock is pulled low after the last data bit until this register is written.

| 1 | ACKOVAL | RW | 0 | I ² C Slave ACK Override Value Value Description 0 An ACK is sent indicating valid data or command. 1 A NACK is sent indicating invalid data or command. |
| 0 | ACKOEN | RW | 0 | I ² C Slave ACK Override Enable Value Description 0 A response is not provided. 1 An ACK or NACK is sent according to the value written to the ACKOVAL bit. |

21.8 Register Descriptions (I²C Status and Control)

The remainder of this section lists and describes the I²C status and control registers, in numerical order by address offset.

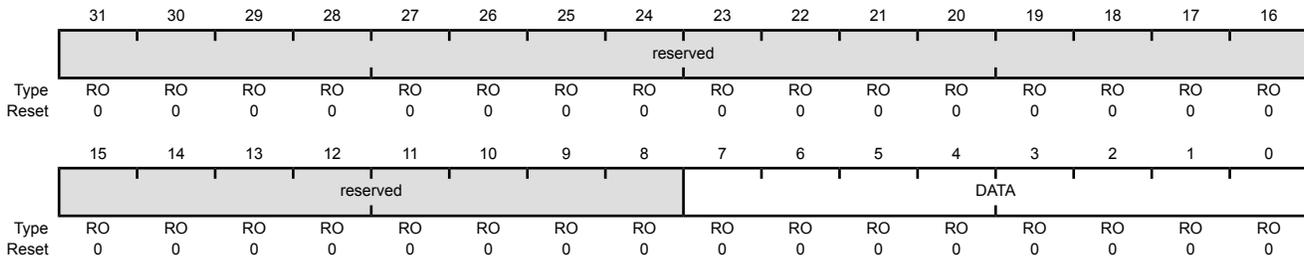

Register 23: I²C FIFO Data (I2CFIFODATA), offset 0xF00

The I²C FIFO Data (I2CFIFODATA) register contains the current value of the top of the RX or TX FIFO stack being used in the a transfer.

Read-Only Status Register

I2C FIFO Data (I2CFIFODATA)

I2C 0 base: 0x4002.0000
 I2C 1 base: 0x4002.1000

| | | | | Value Description |
| | | | 0 | The interface is set to Standard, Fast or Fast mode plus operation. |
| | | | 1 | The interface is set to High-Speed operation. Note that this encoding may only be used if the HS bit in the I2CPP register is set. Otherwise, this encoding is not available. |

22 1-Wire Master Module

The 1-Wire Master module is a bi-directional serial communication interface that implements the protocol functions of the Dallas Semiconductor 1-Wire protocol and provides both power and data over a single wire. The 1-Wire Master module can interface with a multiple variety of slaves such as thermometers, mixed-signal devices, memory, and authentication devices.

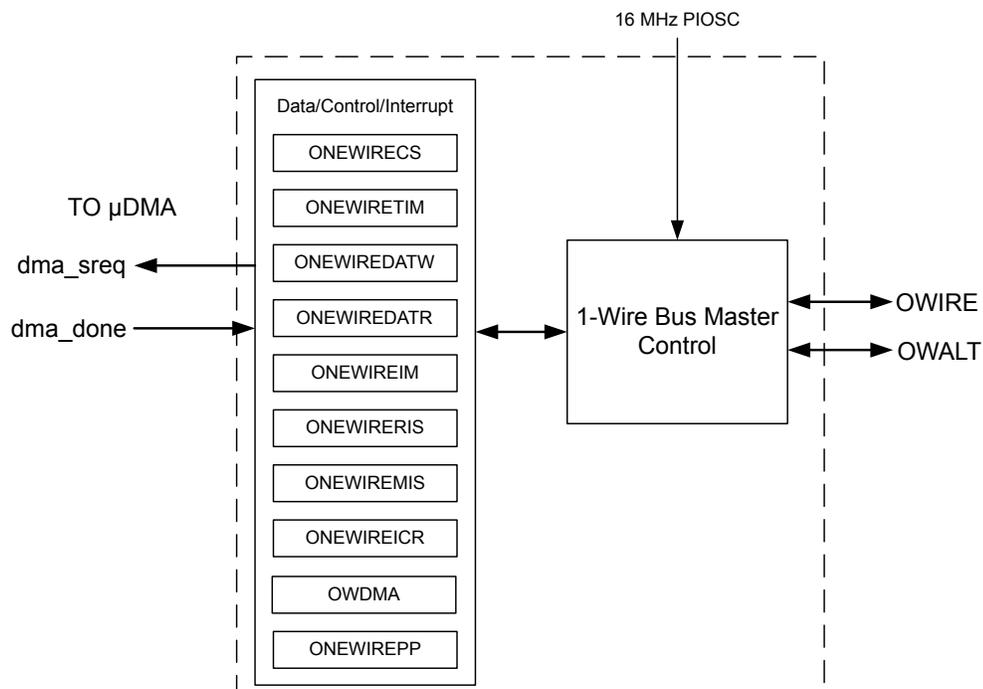

The TM4C129XKCZAD microcontroller includes a 1-Wire Master module with the following features:

- Support for standard and overdrive speeds, including a late-sample mechanism
- Allows transfers of send, receive and bi-directional bits
- Data size transfers of 1, 2, 3, or 4 bytes with sub-byte search and enumeration support
- Interrupt capability for transaction pacing and line error
- Optional two-wire support for isolated lines and high voltage use
- Efficient transfers using Micro Direct Memory Access Controller (μ DMA)

22.1 Block Diagram

Figure 22-1 on page 1508 details the components of the 1-wire Master Module. The clock source for the 1-Wire Master module is the 16-MHz precision internal oscillator (PIOSC).

Figure 22-1. 1-Wire Block Diagram

22.2 Signal Description

The following table lists the external signals of the 1-Wire module and describes the function of each. The 1-Wire module signals are alternate functions for GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the GPIO pin placements for the 1-Wire signals. The **AFSEL** bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 803) should be set to choose the 1-Wire function. The number in parentheses is the encoding that must be programmed into the **PMC_n** field in the **GPIO Port Control (GPIOCTL)** register to assign the 1-Wire signal to the specified GPIO port pin. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 772.

Table 22-1. 1-Wire Signals (212BGA)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description |
|----------|-------------------------------------|--|----------|-------------|---|
| OWALT | K15 B12 | PG5 (5) PP5 (4) | I/O | TTL | 1-Wire Optional 2nd signal to be used as output. |
| OWIRE | G2 K17 V12 U14 D8 A8 | PE3 (5) PG4 (5) PG6 (5) PG7 (5) PP4 (4) PP7 (5) | I/O | TTL | 1-Wire Single Bus Pin. This signal is input only if 1-Wire Alternate Output is enabled. |

22.3 Functional Description

1-Wire is a simple single-wire communication interface comprising a wire protocol, transport protocol, and base session protocols (as well as some basic commands). The wire protocol generates 0s and 1s by varying the time the line is held low (it is pulled up by a resistor). The TM4C129XKCZAD microcontroller is the master and controls the line at all times. A pull-up keeps the line parked high and the microcontroller driver is assumed to be normal open-drain. No special GPIO configuration is needed here since the open-drain support is taken care of outside of the microcontroller. See Table 10-4 on page 786 for pin configuration information. Data can be both read and written on the same 1-Wire pin. The 1-Wire module supports the most basic aspects of the protocol, including wire protocol, byte transport control and line reset. Software is expected to handle the session protocol, including selection of a slave (when more than one is on the same line) and higher level commands.

Note: All time values by the 1-Wire Master are stated in μs , but the actual time on the wire may be less by 62.5 ns.

22.3.1 1-Wire Protocol

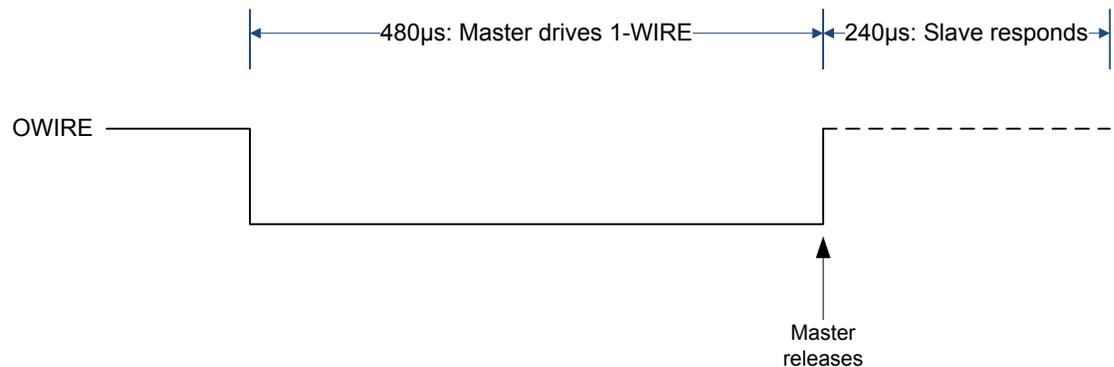

The 1-Wire protocol signals 1s and 0s by holding the line low for varying lengths of time as described below. For details on the operation of this device, see "Overdrive" on page 1513. Before a command is sent, a reset is issued on the line. This is a two-part operation:

- The 1-Wire Master module drives and holds line low for $>480 \mu\text{s}$.
- The controller waits for an answer-to-reset from one or more slaves. A slave signals a reset by pulling the line low for $60 \mu\text{s}$ to $240 \mu\text{s}$. If the line is not sampled low, there is no slave on the bus and the **NOATR** bit is set in the **1-Wire Control and Status (ONEWIRECS)** register. An interrupt mask can also be set to trigger an interrupt on this condition. If the line is sampled low, it indicates there are one or more slaves on the 1-Wire bus. The Master samples the line some period after releasing the line, taking into consideration the time needed for the slave to respond. The time from reset release to first sample is programmed through the **ATRSAM** bit in the **1-Wire**

Timing Override (ONEWIRETIM) register. For example, the Master could sample 10 μs after releasing the reset for 240 μs . Caution should be exercised to make sure the line has been pulled high (by a pull-up) before the Master samples to avert a bogus answer-to-reset. Because the slave may hold the line low for a longer duration than the sample time, the Master must wait for the line to go high before starting a new command. This reset protocol is used to ensure that all slaves are in a known state.

Figure 22-2 on page 1510 shows the details of the 1-wire reset.

Figure 22-2. 1-Wire Reset Protocol

If the Master is transmitting data to the slave, the signalling is as follows:

- A 1 is signaled by the master driving and holding the line low for $<15 \mu\text{s}$. Generally, about $6 \mu\text{s}$ is used for normal mode. The slave samples and measures the signal from falling edge and checks the line $15 \mu\text{s}$ later (or more). If line has reverted to high, the slave registers a 1 value.
- A 0 is signaled by the Master driving and holding the line low for $60 \mu\text{s}$ or more. Although the slave reads just past $15 \mu\text{s}$, the normal mode requires the line to be low for $60 \mu\text{s}$. If the line is still low after $15 \mu\text{s}$, a value of 0 is registered.

Figure 22-3 on page 1511 depicts a 1-Wire Master transmitting a 1 to a slave. Figure 22-4 on page 1511 shows a 1-wire Master transmitting a 0 to a slave.

Figure 22-3. 1-Wire Master Transmitting a 1

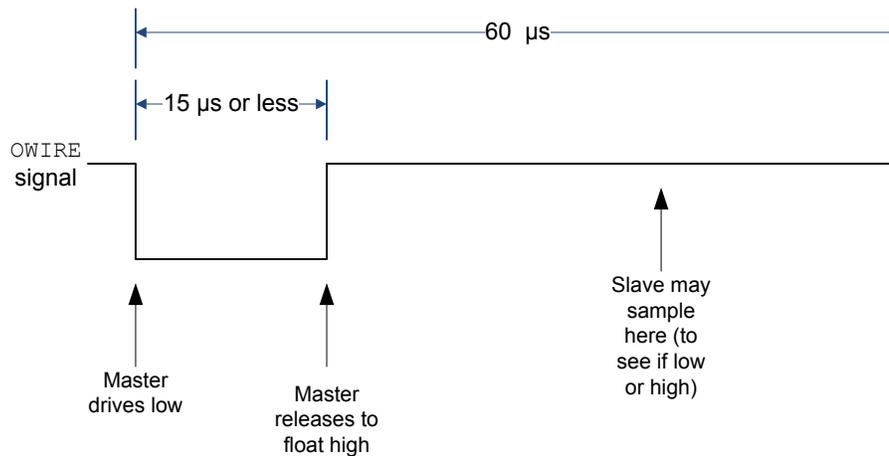

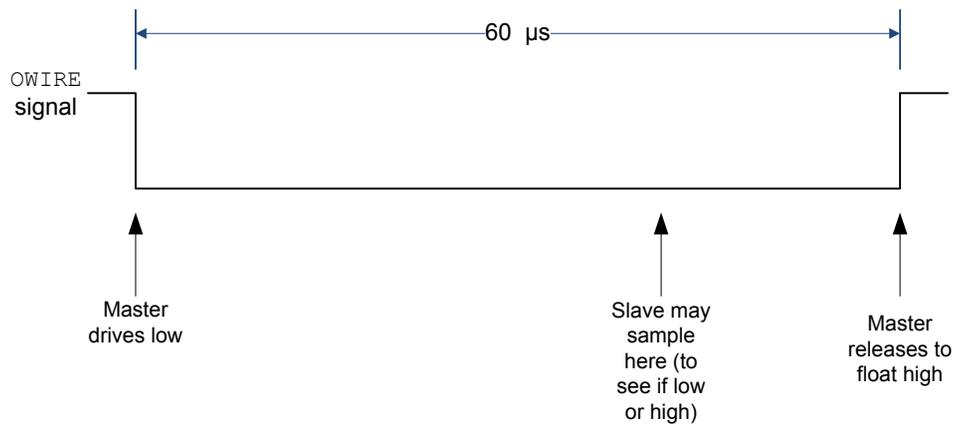

Figure 22-4. 1-Wire Master Transmitting a 0'

For a read from the slave, the Master drives and holds the line low for at least $1\mu\text{s}$ (but less than $15\mu\text{s}$) and then releases. A typical hold time is $6\mu\text{s}$; in other words, it uses a transmitted 1. The read is performed as:

- A 1 is signaled by the slave when "does nothing." Thus, the slave just allows the line to come back up when the master releases it. The master samples the line at $15\mu\text{s}$ after the low edge and the line is still high, signaling a 1.
- If the slave holds the line down for more than $5\mu\text{s}$ (and no more than $60\mu\text{s}$), a 0 is signaled. The master samples the line at $15\mu\text{s}$ after the low edge, and because the line is low still, it is treated as a 0.

Figure 22-5 on page 1512 depicts a Master receiving a 1 value from a slave. Figure 22-6 on page 1512 shows the slave sending a 0 value to a Master.

Figure 22-5. 1-Wire Master Receiving a 1 Signal from a Slave

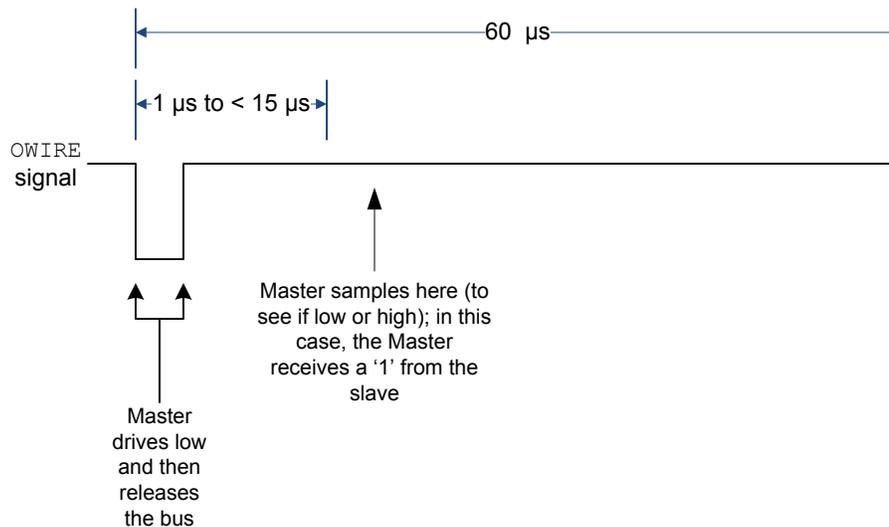

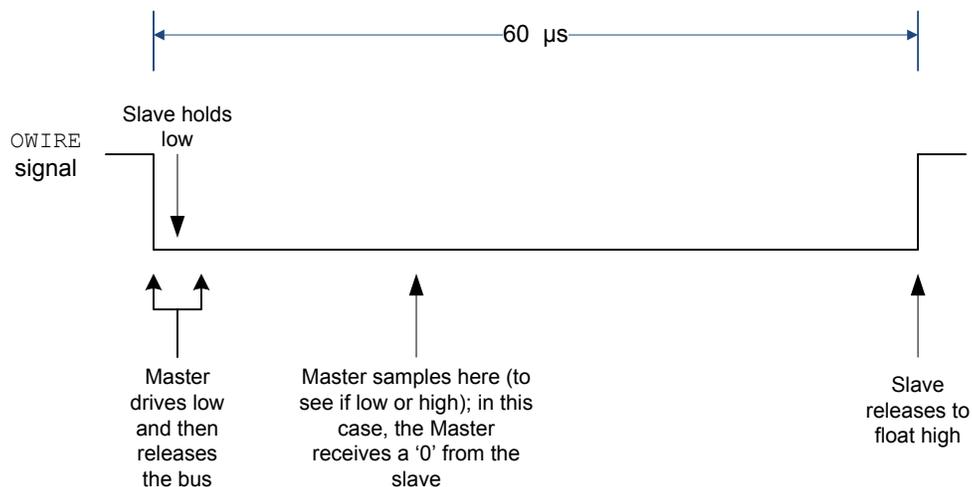

Figure 22-6. 1-Wire Master Receiving a 0 Signal from a Slave

22.3.2 Transport Protocol

The transport level protocol follows a simple model, in part based on treating most 1-wire devices as memory like (IDs, ROM, EEPROM, etc) even if some are sensors or actuators. All commands and data are in 8-bit (byte) quantities and the post-reset commands are pre-defined. The basic protocol is:

- Reset the line by driving and holding the OWIRE signal low for $>480 \mu\text{s}$.
- Wait for answer-to-reset from one or more slaves. Answer-to-reset (ATR) is defined as each slave pulling the line low for $60 \mu\text{s}$ to $240 \mu\text{s}$. If the line does not go low, there is no slave on the bus. If it does, there is one or more.
- At this point the Master either figures out the ID of the slaves on the bus using the enumeration scheme, or selects a slave to issue a command. The "select" command to use is based on

whether there is one slave or more than one. If there is only one slave device, the Master skips the selection process. If more than one are present, the Master selects a slave by sending out the ID for the selected slave, indicating to the remaining slaves that any further commands should be ignored until after the next reset.

- The Master sends a command followed by a sending or receiving of data. While most commands are implemented using bytes read or written, some commands use bytes where some bits are written and some read. Since a read looks like a write 1, if the line is held and driven low for less than 15 μs and the slave does not know it is supposed to reply, the line remains untouched and is read as a 1 (and written as a 1).
- Usually at the end of one or more commands to that slave, a reset is issued again.

The 1-Wire module supports reset and answer-to-reset on request (although answer-to-reset can be suppressed). It also supports byte operations. The software chooses which read, write, or mixed operation to use. Partial byte (bit or multi-bit) is also supported.

22.3.3 Overdrive

The 1-Wire Module also allows for an "overdrive" speed to be selected for shorter line lengths. Overdrive is about ten times faster because it uses smaller time periods. It is agreed by both master and slave before enabling. Overdrive is selected using the `ODRV` bit of the **1-Wire Control and Status (ONEWIRECS)** register.

In overdrive mode, the time periods shrink. Table 22-2 on page 1513 shows the active time for 1-Wire operations in overdrive mode. For example, the Master typically drives and holds the line low for 15 μs for a write 1, but in overdrive mode this is 1 μs .

Table 22-2. Active Time Periods in Overdrive Mode

| Operation | Time | Notes |
|-----------------|-------------------------------------|--|
| Write 1 | 1 μs low | Less than 2 μs low |
| Write 0 | 7.5 μs low | Up to 10 μs low |
| Read 1 | 1 μs low | Master samples at 2 μs |
| Read 0 | 9 μs low | Slave holds at least 7 μs |
| Reset | 70 μs low | Note 2 μs delay before reset for safety |
| Answer to Reset | 4 μs to 48 μs | Master samples at 8.5 μs |

22.3.4 Timing Override

The 1-Wire module can manually override timing for any main action. Each non-zero value in the **1-Wire Timing Override (ONEWIRETIM)** register replaces the default normal or overdrive time rule.

The time factors that can be controlled:

Table 22-3. Bit Field Definitions for 1-Wire Timing and Override (ONEWIRETIM) Register

| Name | Meaning | Range (if used) | Scale | Default (normal) | Default (overdrive) |
|--------------------|--|------------------------|-----------------------|------------------|---------------------|
| <code>W1TIM</code> | Amount of time to drive and hold line low for a write 1 | 1 to 15 μs | 1 μs units | 6 μs | 1 μs |
| <code>W0TIM</code> | Amount of time to drive and hold line low for write 0 ^a | 4 to 124 μs | 4 μs units | 60 μs | 7.5 μs |

Table 22-3. Bit Field Definitions for 1-Wire Timing and Override (ONEWIRETIM) Register
(continued)

| Name | Meaning | Range (if used) | Scale | Default (normal) | Default (overdrive) |
|--------|--|--------------------|------------------|-------------------------|---------------------|
| WOREST | Amount of time to hold line high after a write 0 (rest) ^a | 1 to 15 μ s | 1 μ s units | 10 μ s | 2.5 μ s |
| WLSAM | Amount of time after 1-Wire has released the line to sample slave holding line | 1 to 15 μ s | 1 μ s units | 10 μ s | 1 μ s |
| RSTTIM | Amount of time to drive and hold line low for a reset. Allow for an additional 2- μ s pre-reset period | 32 to 2016 μ s | 32 μ s units | 480 μ s | 70 μ s |
| ARTTIM | Period of answer-to-reset or rest. The ATRSAM bit value must be considered when programming this field. ARTTIM must be greater than ATRSAM to avoid a STUCK fault generation | 16 to 496 μ s | 16 μ s units | 240 μ s | 48 μ s |
| ATRSAM | Period in which first sample occurs in answer-to-reset (after line goes high). If the SKATR bit is set in the ONEWIRECS register, this value indicates the rest period after reset | 8 to 120 μ s | 8 μ s units | 10 μ s ^b | 2 μ s |

a. If WOTIM has been programmed to a non-default value, WOREST must be programmed for correct functionality.

b. ATRSAM is the first sample. If the line is high, it continues sampling for the rest of ARTTIM period to see if goes low. This subsequent sampling is every 62.5 ns. Thus, this value must be long enough to be sure the line has floated high, but does not have to be after the time the slaves have driven low. This rule is different than a single sample model, which can be too late or miss on long lines.

22.3.5 Command Protocol

The standard 1-Wire protocol has commands to be used after a reset. These commands normally include slave selection and detection. However, many 1-Wire buses only have one slave, and in that case, those mechanisms can be skipped. If slave management is needed, a small software stack can be used to handle these operations. Other protocols can also be easily supported, whether byte-oriented (as normal) or bit-oriented. To support an alternative protocol, it is usually necessary to override some or all of the timing and may be necessary to disable the answer-to-reset mechanism using the SKATR bit in the ONEWIRECS register. The module is designed to support the most common uses of 1-Wire, including a mechanism to allow a reset followed by an operation of 1, 2, 3, or 4 bytes through the SZ bit in the ONEWIRECS register. Additionally, the OP bit supports a write/read model to allow a mix of write and read in one transaction. Although nominally mixed mode allows for a mix of write and read bytes, it can be used down to the bit level.

The following represents some typical operation flows:

1. To only send a reset, the RST bit of the ONEWIRECS register is set, performing a reset and triggering an interrupt if enabled. If there is no answer-to-reset, the NOATR status bit is set and the corresponding interrupt bit can be set as well.
2. The SZ and OP fields of the ONEWIRECS register are used to perform a write, a read, or a combination. For small transactions, the SZ encoding can be programmed for processing of up to 4 bytes in one transaction. For larger transactions, the OP field can be used multiple times. The OPC raw interrupt bit is used to notify when a transaction is complete.
3. To perform a reset and then a transaction, both the RST and OP/SZ fields of the ONEWIRECS register are configured. The reset runs to completion and then the transaction starts. The interrupt is used to notify when both are done.

To setup a read, write or mixed transaction, the following configuration needs to occur:

- For writes, the **1-Wire Data Write (ONEWIREDATW)** register must first be written with one, two, three or four bytes to send (as a word). Next the **ONEWIRECS** register is configured as described above.
- For reads, the **ONEWIRECS** register is written as described above. Then, when the transaction is complete, the **1-Wire Data Read (ONEWIREDATR)** register is read to collect the one, two, three or four bytes that were received (as a word).
- For write/read combination, the **ONEWIREDATW** register is written with one, two, three or four bytes to write or read. Then, the **ONEWIRECS** register is configured as described above. As the data is transferred from the **ONEWIREDATW** register to the 1-Wire line, any 1 that is transmitted creates a read that is registered in the **ONEWIREDATR** register. When the entire transaction is complete, the **ONEWIREDATR** register can be read to collect the bytes that were received by the 1-Wire Master. A **ONEWIREDATR** register bit contains a 0 for any bit that was written as a 0, a 1 for any bit that was written as a 1 or any bit not modified by the slave (may have been intentional 1 or ignored) and a 0 for any bit written as a 1 but read back as a '0.'

22.3.6 Search (Enumeration) and Sub-Byte

Although 1-Wire is a byte protocol, there are times when less than a byte must to be written or read. By programming the **BSIZE** field of the **ONEWIRECS** register, the number of bits to write and or read in the last byte can be configured. The **BSIZE** field can be used for a 1-Wire search (enumeration) to allow detect and select processing. Enumeration begins by executing the standard **SEARCH (0xF0)** command (and if available, the **ALARM SEARCH (0xEC)**) and then reading two bits for the ID, which is the first bit and its complement. Subsequently, a bit is emitted to select devices with that first matching bit followed by another read of two bits. This process is repeated for up to all 64 bits. To start over, a reset is used. In this way, a tree of IDs can be broken down until one unique ID is left. This can be repeated for each device. The **BSIZE** field can also be used for non-standard devices which do not fully follow protocol.

22.3.7 Interrupts

The interrupt model for the 1-Wire module allows interrupt service routines to drive continuations of operations, whether reading the results or processing more bytes. Most command sequences are small, so the module supports transactions of one, two, three, and four bytes at once. Because most commands start with a line reset, the operational model allows for a reset followed by the transaction, with an interrupt occurring when the transaction is complete. There is also support for enabling interrupts for reset complete (**RST**), no answer-to-reset (**NOATR**) and line-hold-low error detected (**STUCK**) in the **1-Wire Interrupt Mask (ONEWIREIM)** register.

22.3.8 DMA

The μ DMA model is designed to support both normal μ DMA operation on write or read, as well as scatter-gather operation. The normal mode of operation allows for continued writes of byte, half-word, or word (three-byte size is not supported by μ DMA for repeated operation) as well as continued reads by byte, half-word, or word. Additionally, the first transaction may be started with a reset.

The **1-Wire DMA Control (ONEWIREDMA)** register is used to configure the μ DMA. To use μ DMA with 1-Wire transmits:

1. Select 1-Wire to use μ DMA by programming the **DMA Channel Map Select n (DMACHMAPn)** register in the μ DMA. See "Channel Assignments" on page 710 for more information.

2. Configure the μ DMA to transfer bytes, half-words, or words from memory to the 1-Wire **ONEWIREDATW** register or from the **ONEWIREDATR** register through the **DMA Channel Control Word (DMACHCTL)** register (see page 735).
3. Set the *SZ* field of the **ONEWIRECS** register to byte, half-word, or word (0, 1, or 3). This is the only field programmed in the **ONEWIRECS** register.
4. Enable the DMA completion interrupt in the **ONEWIREIM** register. It is also recommended that the *ERR* and *NOATR* interrupts should be enabled when using the μ DMA to ensure that the application is notified if the reset or transaction failed.
5. Write the *DMAOP* field of the **ONEWIREDMA** register with the encoding 0x2 to enable the 1-Wire module assert a μ DMA request when **ONEWIREDATW** is empty. The *RST* bit in the **ONEWIREDMA** register can be set for reset to be asserted first before requesting a μ DMA access.
6. When the μ DMA transfer is complete, the *DMA* bit in the **1-Wire Raw Interrupt Status (ONEWIRERIS)** register is set and the **ONEWIREDMA** register is cleared.

A 1-Wire μ DMA receive configuration is as follows:

1. Select 1-Wire to use μ DMA by programming the **DMA Channel Map Select n (DMACHMAPn)** register in the μ DMA. See “Channel Assignments” on page 710 for more information.
2. Configure the μ DMA to transfer bytes, half-words, or words from the 1-Wire **ONEWIREDATR** register through the **DMA Channel Control Word (DMACHCTL)** register (see page 735).
3. Enable the DMA completion interrupt in the **ONEWIREIM** register. It is also recommended that the *ERR* and *NOATR* interrupts should be enabled when using the μ DMA to ensure that the application is notified if the reset or transaction failed.
4. Write the *DMAOP* field of the **ONEWIREDMA** register with the encoding 0x1 or 0x3 to enable a read or read multiple by the μ DMA. The *RST* bit in the **ONEWIREDMA** register can be set for reset to be asserted first before requesting a μ DMA access.
5. Write the **ONEWIREDATW** register with 0xFFFF.FFFF to prime the read operations. If the *RST* bit is not set in the **ONEWIREDMA** register, the transaction begins. If *RST* was set, the read starts when reset is complete. At the end of the read operation, the μ DMA receives a request to transfer the data from the **ONEWIREDATR** register. If the *DMAOP* bit was configured for a multiple read (0x3), then the next read transaction will automatically start. If not, then no further μ DMA requests occur unless **ONEWIREDATR** is written to.
6. When a μ DMA receive is complete, the *DMA* bit in the **1-Wire Raw Interrupt Status (ONEWIRERIS)** register is set and the **ONEWIREDMA** register is cleared.

The normal flow for writing/reading in one operation is:

1. Configure the *DMAOP* bit in the **ONEWIREDMA** register for a read, and optionally set the *RST* bit. If *RST* is selected, the reset is performed first, else the module waits for the next step.
2. Write the **ONEWIREDATW** register with one, two, or four bytes containing the mix of writes and reads. For example, to write 0x46, 0x20, and then read 2 bytes, set size to word (*SZ*=3) and write **ONEWIREDATW** with 0xFFFF2046 to send the 0x46 and 0x20 and then read the last two bytes. On completion, the **ONEWIREDATR** contains the read values in the upper two bytes. If

RST is not set in the **ONEWIREDMA** register, the transaction starts. If RST is set, the transaction starts when reset completes. At the end of the operation, the μ DMA is requested to transfer the data from the **ONEWIREDATR** register (read).

3. When the μ DMA is done, the DMA bit in the **ONEWIRERIS** register is set, allowing interrupt on completion by μ DMA, and the **ONEWIREDMA** register is cleared.

It is recommended to enable trigger interrupts for ERR and NOATR when using μ DMA so application is notified if reset or the transaction failed.

The natural model for using scatter-gather is:

1. Enable peripheral-scatter-gather in the μ DMA module by programming the **DMA Channel Control Word (DMACHCTL)** register.
2. Set the DMAOP to read (not read multiple) and enable scatter gather in the 1-Wire module by setting the SG bit to 0x1 in the **ONEWIREDMA** register. This allows use of **ONEWDATW** register to push through transactions, with μ DMA request being triggered off completion, except for the first transaction.
3. Scatter gather can then use a combination of write and read as needed.

22.3.9 1-Wire Timing

The 1-Wire module wire control operates using the Precision Internal Oscillator (PIOSC) to provide a reliable frequency with no need for baud dividers. The register interface operates using the system clock, which may be a different clock source. However, there is no visible impact from this separate clock model. Normal rules apply to use of the registers to ensure correct operation. In particular:

- The control register is used live (not buffered) by the communication engine. Once an operation is started, it must be allowed to finish before changes are made, such as starting a new operation or changing speed. The status bits in the **ONEWIRECS** register notify the application if the transaction is busy or if a line-hold-low error is detected. When the last write, read or read/write has occurred, the OPC bit is set in the **ONEWIRERIS** register.
- Data read by the 1-Wire Master is not valid or meaningful until the 1-Wire module signals that the data is ready (via interrupt, DMA, and status).
- Data written should be written before the operation is started and then should not be re-written until the 1-Wire module signals the data has been written (via interrupt, DMA, and status).
- The **1-Wire Timing Override (ONEWIRETIM)** register should not be changed while a transaction is taking place.

The **ONEWIREIM**, **ONEWIRERIS** and **ONEWIREMIS** registers may be written and read at any time with no risk.

22.4 Initialization and Configuration

The whole block may be enabled or disabled using the system control registers. The following example shows how to enable, force a reset and send a command.

1. Enable the 1-Wire Module by writing a value of 0x0000.0001 to the **1-Wire Run Mode Clock Gating Control (RCGCOWIRE)** register in the System Control Module, see page 420.

2. Enable the clock to the appropriate GPIO port that is used for the 1-Wire signals using the **General-Purpose Input/Output Run Mode Clock gating Control (RCGCGPIO)** in the System Control Module; see page 399. To find out which GPIO port to enable, refer to Table 31-5 on page 2081.
3. In the GPIO module, enable the appropriate pin for its alternate function using the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 803).
4. Configure the PMC_n fields in the **GPIOPCTL** register to assign the 1-Wire signals to the appropriate pins. See page 820 and Table 31-5 on page 2081.
5. Optionally enable interrupts to be notified when the transactions completes.
6. Write to the **ONEWIREDATW** register with the data to write (1, 2, 3, or 4 bytes).
7. Write to the **ONEWIRECS** register to set the RST bit and configure the OP (operation) and SZ fields. When configuring all three bit fields, the reset is performed first, followed by the operation (unless an error occurs) and then any interrupt triggers.
8. If normal interrupts are generated (for example, OPC and RST), clear these interrupts and read the **ONEWIREDATR** register if a read or read/write transaction occurred.
9. If the 1-Wire master has more data to write and/or read for the same command, repeat the previous two steps but without setting the RST bit. If a new command is required, repeat the previous two steps including the reset enable.

22.5 Register Map

Table 22-4 on page 1518 lists the 1-Wire Master Module registers. The offset listed is a hexadecimal increment to the register's address, relative to the 1-Wire Master module's base address 0x400B.6000.

Table 22-4. OWIRE Register Map

| Offset | Name | Type | Reset | Description | See page |
|--------|-------------|------|-------------|--------------------------------|----------|
| 0x000 | ONEWIRECS | RW | 0x0000.0000 | 1-Wire Control and Status | 1520 |
| 0x004 | ONEWIRETIM | RW | 0x0000.0000 | 1-Wire Timing Override | 1524 |
| 0x008 | ONEWIREDATW | RW | 0x0000.0000 | 1-Wire Data Write | 1525 |
| 0x00C | ONEWIREDATR | RW | 0x0000.0000 | 1-Wire Data Read | 1526 |
| 0x100 | ONEWIREIM | RW | 0x0000.0000 | 1-Wire Interrupt Mask | 1527 |
| 0x104 | ONEWIRERIS | RO | 0x0000.0000 | 1-Wire Raw Interrupt Status | 1529 |
| 0x108 | ONEWIREMIS | RO | 0x0000.0000 | 1-Wire Masked Interrupt Status | 1531 |
| 0x10C | ONEWIREICR | RW1C | 0x0000.0000 | 1-Wire Interrupt Clear | 1533 |
| 0x120 | ONEWIREDMA | RW | 0x0000.0000 | 1-Wire μ DMA Control | 1534 |
| 0xFC0 | ONEWIREPP | RO | 0x0000.0011 | 1-Wire Peripheral Properties | 1536 |

22.6 1-Wire Master Register Descriptions

This section lists and describes the 1-Wire Master Module registers, in numerical order by address offset.

Register 1: 1-Wire Control and Status (ONEWIRECS), offset 0x000

The **1-Wire Control and Status (ONEWIRECS)** register contains the control and status bits for the 1-Wire bus, including active state and passive detection. The **OP** field is written to start an operation. If executing a write or a write/read, the **Bn** field of the **1-Wire Data Write (ONEWIREDATW)** register must be written first before programming the **OP** field.

1-Wire Control and Status (ONEWIRECS)

Base 0x400B.6000

Offset 0x000

Type RW, reset 0x0000.0000

| | | | | | | | | | | | | | | | | |

| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit/Field | Name | Type | Reset | Description |
|-----------|--------|------|-------|--|
| 31:28 | W1TIM | RW | 0 | Value 1 Timing This field indicates the time low for a 1 in μ s units. |
| 27:23 | W0TIM | RW | 0 | Value 0 Timing Indicates time low for a 0 in 4 μ s units. Note: If W0TIM has been programmed to a non-default value, W0REST must be programmed for correct functionality. |
| 22:19 | W0REST | RW | 0 | Rest Time This field indicates time to rest after a 0 in 1 μ s units. Note: If W0TIM has been programmed to a non-default value, W0REST must be programmed for correct functionality. |
| 18:15 | W1SAM | RW | 0 | Sample Time Time to sample for a 1 vs 0 in μ s after the release of the line by 1-Wire. The LSAM bit is ignored if this bit is set. |
| 14:11 | ATRSAM | RW | 0 | Answer-to-Reset Sample Time to first sample for answer-to-reset in 8 μ s units. Sampling continues until time indicated by ATRTIM bit. Note: When programming ATRTIM and ATRSAM, the value of ATRTIM must be greater than ATRSAM to prevent the line from being flagged as STUCK. |
| 10:6 | ATRTIM | RW | 0 | Answer-to-Reset/Rest Period This field indicates the answer-to-reset period in 16 μ s units. If the SKATR bit is set in the ONEWIRECS register, this value indicates the rest period after reset. Note: When programming ATRTIM and ATRSAM, the value of ATRTIM must be greater than ATRSAM to prevent the line from being flagged as STUCK. |
| 5:0 | RSTTIM | RW | 0 | Reset Low Time Indicates the time reset is low in 32 μ s units. |

Register 3: 1-Wire Data Write (ONEWIREDATW), offset 0x008

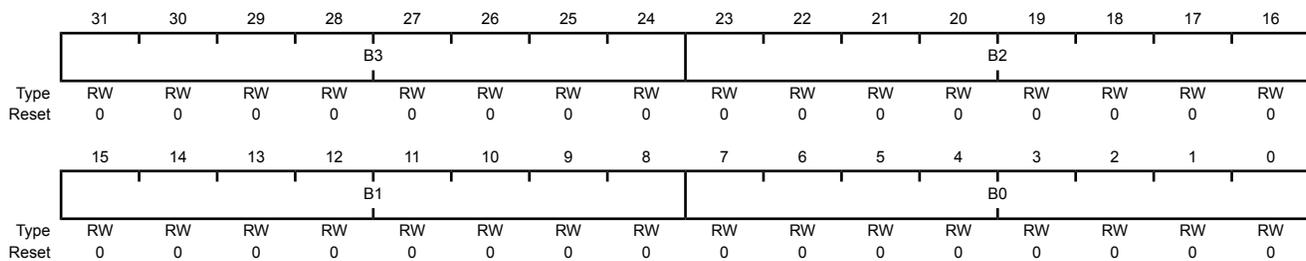

The **1-Wire Data Write (ONEWIREDATW)** and **1-Wire Data Read (ONEWIREDATR)** registers are used to transmit or receive data. Data is processed LSB first, which means the lowest (and possibly only) byte is transferred first. Note that for normal processor use of writing and write/read, the **ONEWIREDATW** register must be written before the **OP** field of the **ONEWIRECS** register is programmed. If reading (or write/read), the **ONEWIREDATR** register is read after completion (when **OP** returns to value 0). When doing write/read (**OP**=0x3), either register can be written. Because bits written as a 1 in the **ONEWIREDATR** register also act as a read, writing 0xFF is the same as a read of two bytes. Writing 0xF0 allows writing 0 for the lower nibble and reading the upper nibble. If the slave does not know it is a read, each written 1 reads back as 1.

1-Wire Data Write (ONEWIREDATW)

Base 0x400B.6000

Offset 0x008

Type RW, reset 0x0000.0000

| Bit/Field | Name | Type | Reset | Description |
|-----------|------|------|-------|---|
| 31:24 | B3 | RW | 0x00 | Upper Data Byte This data byte is used when <i>SZ</i> field = 3. |
| 23:16 | B2 | RW | 0x00 | Upper Middle Data Byte Contains upper middle data byte and is used when <i>SZ</i> field = 2 or 3. |
| 15:8 | B1 | RW | 0x00 | Lower Middle Data Byte Contains lower middle data byte and is used when <i>SZ</i> field = 1, 2, or 3. |
| 7:0 | B0 | RW | 0x00 | Lowest Data Byte Contains byte data being read or written (depending on the operation). This byte is always used. |

Register 4: 1-Wire Data Read (ONEWIREDATR), offset 0x00C

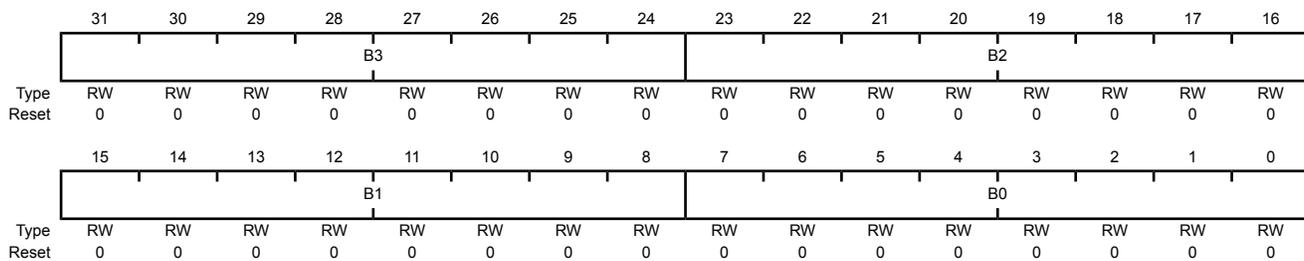

The **1-Wire Data Write (ONEWIREDATW)** and **1-Wire Data Read (ONEWIREDATR)** registers are used to transmit or receive data. Data is processed LSB first, which means the lowest (and possibly only) byte is transferred first. Note that for normal processor use of writing and write/read, the **ONEWIREDATW** register must be written before the **OP** field of the **ONEWIRECS** register is programmed. If reading (or write/read), the **ONEWIREDATR** register is read after completion (when **OP** returns to value 0). When doing write/read (**OP**=0x3), either register can be written. Because bits written as a 1 in the **ONEWIREDATR** register also act as a read, writing 0xFF is the same as a read of two bytes. Writing 0xF0 allows writing 0 for the lower nibble and reading the upper nibble. If the slave does not know it is a read, each written 1 reads back as 1.

1-Wire Data Read (ONEWIREDATR)

Base 0x400B.6000

Offset 0x00C

Type RW, reset 0x0000.0000

| Bit/Field | Name | Type | Reset | Description |
|-----------|------|------|-------|---|
| 31:24 | B3 | RW | 0x00 | Upper Data Byte This data byte is used when <i>SZ</i> field = 3. |
| 23:16 | B2 | RW | 0x00 | Upper Middle Data Byte Contains upper middle data byte and is used when <i>SZ</i> field = 2 or 3. |
| 15:8 | B1 | RW | 0x00 | Lower Middle Data Byte Contains lower middle data byte and is used when <i>SZ</i> field = 1, 2, or 3. |
| 7:0 | B0 | RW | 0x00 | Lowest Data Byte Contains byte data being read or written (depending on the operation). This byte is always used. |

Register 5: 1-Wire Interrupt Mask (ONEWIREIM), offset 0x100

The **1-Wire Interrupt Mask (ONEWIREIM)** register enables the interrupt triggers for the 1-Wire Module.

1-Wire Interrupt Mask (ONEWIREIM)

Register 9: 1-Wire μ DMA Control (ONEWIREDMA), offset 0x120

The **1-Wire DMA Control (ONEWIREDMA)** register is used to configure the μ DMA operation for 1-Wire. This mechanism supports both μ DMA write operations, μ DMA read operations, small write/read operations, and scatter-gather support of mixed operations.

Note: This register is cleared when the `dma_done` signal to the 1-Wire module is asserted by the μ DMA and the `DMA` bit in the **ONEWIRERIS** register is set.

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|------------|---|
| 31:4 | reserved | RO | 0x0000.000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 3 | SG | RW | 0 | Scatter-Gather Enable This bit should be enabled when <code>DMAOP = 0x1</code> and the scatter-gather method is being used. This bit self clears after it has performed the μ DMA request. Value Description 0 No effect 1 μ DMA is requested at start of operation and all requests after are on completion of transactions. |
| 2:1 | DMAOP | RW | 0x0 | μ DMA Operation The programmed operation starts when reset completes if the <code>RST</code> bit in the ONEWIRECS register is set. If <code>RST</code> is not set, then write requests the μ DMA immediately and read starts on a write to the ONEWIREDATW register. Value Description 0x0 μ DMA disabled 0x1 μ DMA single read: 1-Wire requests μ DMA to read ONEWIREDATR register after each read transaction. 0x2 μ DMA multiple write: 1-Wire requests μ DMA to load whenever the ONEWIREDATW register is empty. 0x3 μ DMA multiple read: An initial read occurs and subsequent reads start after μ DMA has read the ONEWIREDATR register. |

| Bit/Field | Name | Type | Reset | Description |
|-----------|------|------|-------|---|
| 0 | RST | RW | 0 | <p>μDMA Reset</p> <p>Value Description</p> <p>0 No effect.</p> <p>1 A reset is issued and no reads and writes should be started until reset is done. Setting this bit sets the RST bit in the ONEWIRECS register. This bit is self-clearing upon reset completion.</p> |

Register 10: 1-Wire Peripheral Properties (ONEWIREPP), offset 0xFC0

The 1-Wire Peripheral Properties (ONEWIREPP) register contains peripheral properties for the 1-Wire module.

23 Controller Area Network (CAN) Module

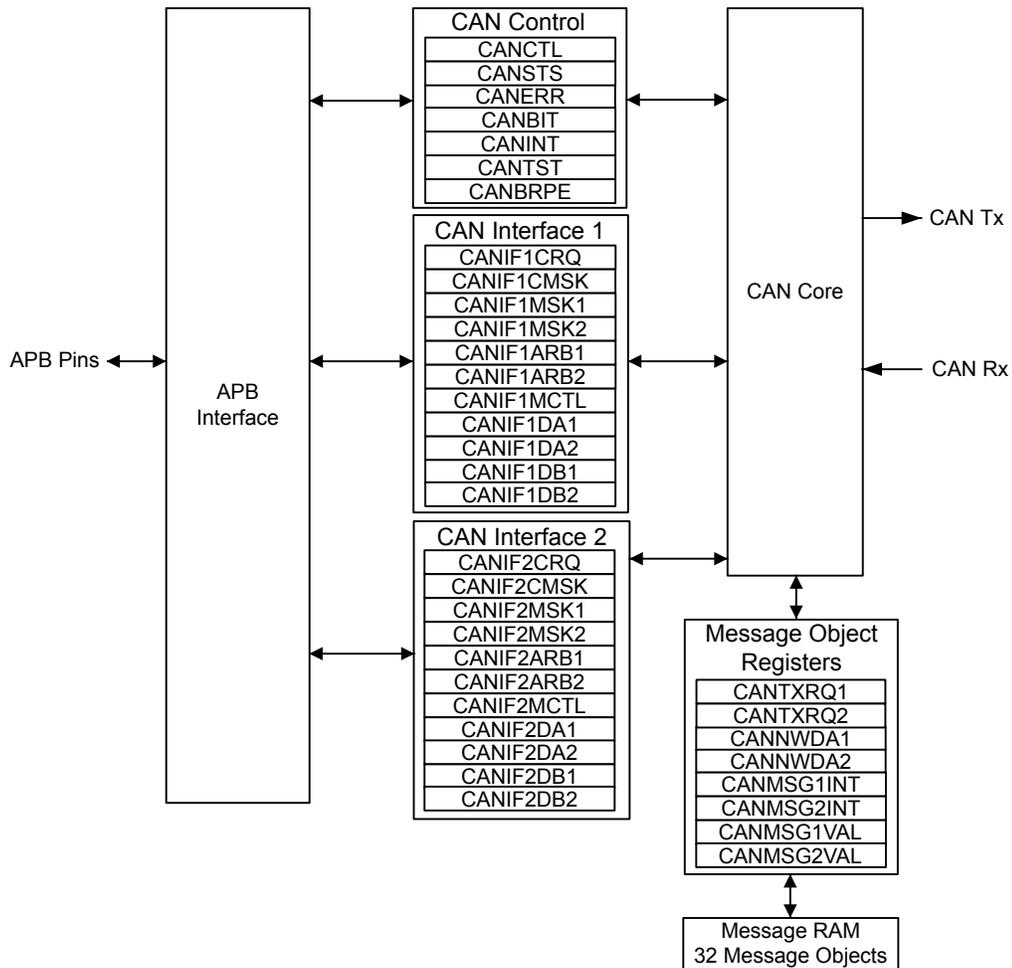

Controller Area Network (CAN) is a multicast, shared serial bus standard for connecting electronic control units (ECUs). CAN was specifically designed to be robust in electromagnetically-noisy environments and can utilize a differential balanced line like RS-485 or a more robust twisted-pair wire. Originally created for automotive purposes, it is also used in many embedded control applications (such as industrial and medical). Bit rates up to 1 Mbps are possible at network lengths less than 40 meters. Decreased bit rates allow longer network distances (for example, 125 Kbps at 500 meters).

The TM4C129XKCZAD microcontroller includes two CAN units with the following features:

- CAN protocol version 2.0 part A/B
- Bit rates up to 1 Mbps
- 32 message objects with individual identifier masks
- Maskable interrupt
- Disable Automatic Retransmission mode for Time-Triggered CAN (TTCAN) applications
- Programmable loopback mode for self-test operation
- Programmable FIFO mode enables storage of multiple message objects
- Gluelessly attaches to an external CAN transceiver through the CAN_nTX and CAN_nRX signals

23.1 Block Diagram

Figure 23-1. CAN Controller Block Diagram

23.2 Signal Description

The following table lists the external signals of the CAN controller and describes the function of each. The CAN controller signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for the CAN signals. The `AFSEL` bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 803) should be set to choose the CAN controller function. The number in parentheses is the encoding that must be programmed into the `PMCn` field in the **GPIO Port Control (GPIOCTL)** register (page 820) to assign the CAN signal to the specified GPIO port pin. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 772.

Table 23-1. Controller Area Network Signals (212BGA)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description |
|----------|------------|--------------------------|----------|-------------|------------------------|
| CAN0Rx | V3 W10 | PA0 (7) PT0 (7) | I | TTL | CAN module 0 receive. |
| CAN0Tx | W3 V10 | PA1 (7) PT1 (7) | O | TTL | CAN module 0 transmit. |
| CAN1Rx | A16 E18 | PB0 (7) PT2 (7) | I | TTL | CAN module 1 receive. |
| CAN1Tx | B16 F17 | PB1 (7) PT3 (7) | O | TTL | CAN module 1 transmit. |

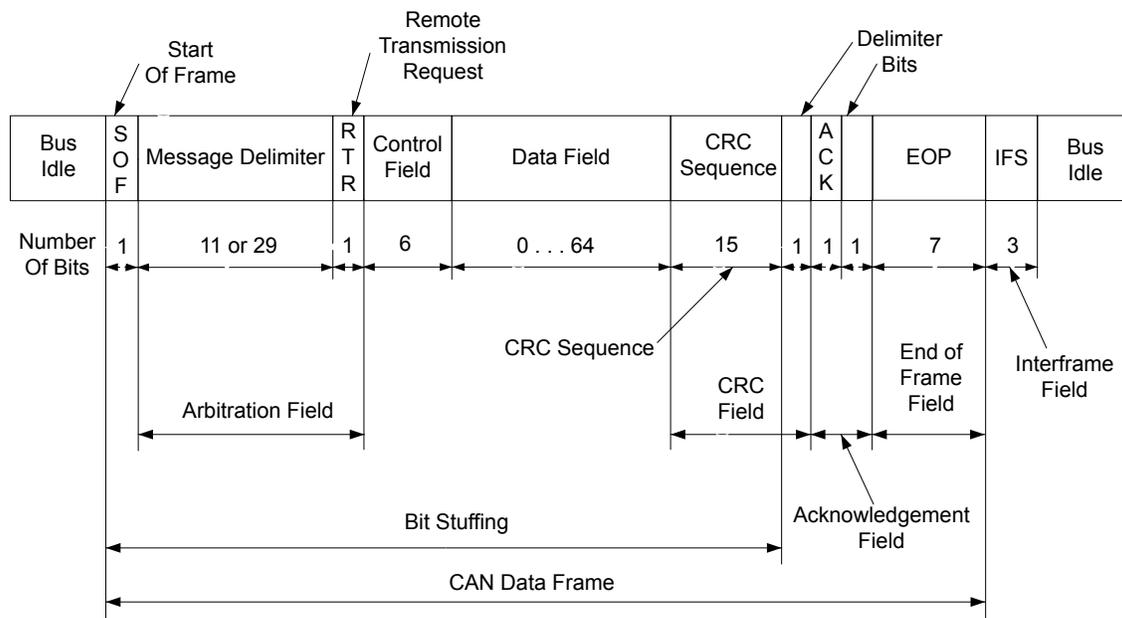

23.3 Functional Description

The TM4C129XKCZAD CAN controller conforms to the CAN protocol version 2.0 (parts A and B). Message transfers that include data, remote, error, and overload frames with an 11-bit identifier (standard) or a 29-bit identifier (extended) are supported. Transfer rates can be programmed up to 1 Mbps.

The CAN module consists of three major parts:

- CAN protocol controller and message handler
- Message memory
- CAN register interface

A data frame contains data for transmission, whereas a remote frame contains no data and is used to request the transmission of a specific message object. The CAN data/remote frame is constructed as shown in Figure 23-2.

Figure 23-2. CAN Data/Remote Frame

The protocol controller transfers and receives the serial data from the CAN bus and passes the data on to the message handler. The message handler then loads this information into the appropriate message object based on the current filtering and identifiers in the message object memory. The message handler is also responsible for generating interrupts based on events on the CAN bus.

The message object memory is a set of 32 identical memory blocks that hold the current configuration, status, and actual data for each message object. These memory blocks are accessed via either of the CAN message object register interfaces.

The message memory is not directly accessible in the TM4C129XKCZAD memory map, so the TM4C129XKCZAD CAN controller provides an interface to communicate with the message memory via two CAN interface register sets for communicating with the message objects. These two interfaces must be used to read or write to each message object. The two message object interfaces allow parallel access to the CAN controller message objects when multiple objects may have new information that must be processed. In general, one interface is used for transmit data and one for receive data.

23.3.1 Initialization

To use the CAN controller, the peripheral clock must be enabled using the **RCGC0** register (see page 412). In addition, the clock to the appropriate GPIO module must be enabled via the **RCGC2** register (see page 412). To find out which GPIO port to enable, refer to Table 31-4 on page 2064. Set the GPIO **AFSEL** bits for the appropriate pins (see page 803). Configure the **PMCn** fields in the **GPIOCTL** register to assign the CAN signals to the appropriate pins. See page 820 and Table 31-5 on page 2081.

Software initialization is started by setting the **INIT** bit in the **CAN Control (CANCTL)** register (with software or by a hardware reset) or by going bus-off, which occurs when the transmitter's error counter exceeds a count of 255. While **INIT** is set, all message transfers to and from the CAN bus are stopped and the **CANnTX** signal is held High. Entering the initialization state does not change the configuration of the CAN controller, the message objects, or the error counters. However, some configuration registers are only accessible while in the initialization state.

To initialize the CAN controller, set the **CAN Bit Timing (CANBIT)** register and configure each message object. If a message object is not needed, label it as not valid by clearing the **MSGVAL** bit in the **CAN IFn Arbitration 2 (CANIFnARB2)** register. Otherwise, the whole message object must be initialized, as the fields of the message object may not have valid information, causing unexpected results. Both the **INIT** and **CCE** bits in the **CANCTL** register must be set in order to access the **CANBIT** register and the **CAN Baud Rate Prescaler Extension (CANBRPE)** register to configure the bit timing. To leave the initialization state, the **INIT** bit must be cleared. Afterwards, the internal Bit Stream Processor (BSP) synchronizes itself to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive recessive bits (indicating a bus idle condition) before it takes part in bus activities and starts message transfers. Message object initialization does not require the CAN to be in the initialization state and can be done on the fly. However, message objects should all be configured to particular identifiers or set to not valid before message transfer starts. To change the configuration of a message object during normal operation, clear the **MSGVAL** bit in the **CANIFnARB2** register to indicate that the message object is not valid during the change. When the configuration is completed, set the **MSGVAL** bit again to indicate that the message object is once again valid.

23.3.2 Operation

Two sets of CAN Interface Registers (**CANIF1x** and **CANIF2x**) are used to access the message objects in the Message RAM. The CAN controller coordinates transfers to and from the Message RAM to and from the registers. The two sets are independent and identical and can be used to

queue transactions. Generally, one interface is used to transmit data and one is used to receive data.

Once the CAN module is initialized and the `INIT` bit in the **CANCTL** register is cleared, the CAN module synchronizes itself to the CAN bus and starts the message transfer. As each message is received, it goes through the message handler's filtering process, and if it passes through the filter, is stored in the message object specified by the `MNUM` bit in the **CAN IFn Command Request (CANIFnCRQ)** register. The whole message (including all arbitration bits, data-length code, and eight data bytes) is stored in the message object. If the Identifier Mask (the `MSK` bits in the **CAN IFn Mask 1** and **CAN IFn Mask 2 (CANIFnMSKn)** registers) is used, the arbitration bits that are masked to "don't care" may be overwritten in the message object.

The CPU may read or write each message at any time via the CAN Interface Registers. The message handler guarantees data consistency in case of concurrent accesses.

The transmission of message objects is under the control of the software that is managing the CAN hardware. Message objects can be used for one-time data transfers or can be permanent message objects used to respond in a more periodic manner. Permanent message objects have all arbitration and control set up, and only the data bytes are updated. At the start of transmission, the appropriate `TXRQST` bit in the **CAN Transmission Request n (CANTXRQn)** register and the `NEWDAT` bit in the **CAN New Data n (CANNWDAn)** register are set. If several transmit messages are assigned to the same message object (when the number of message objects is not sufficient), the whole message object has to be configured before the transmission of this message is requested.

The transmission of any number of message objects may be requested at the same time; they are transmitted according to their internal priority, which is based on the message identifier (`MNUM`) for the message object, with 1 being the highest priority and 32 being the lowest priority. Messages may be updated or set to not valid any time, even when their requested transmission is still pending. The old data is discarded when a message is updated before its pending transmission has started. Depending on the configuration of the message object, the transmission of a message may be requested autonomously by the reception of a remote frame with a matching identifier.

Transmission can be automatically started by the reception of a matching remote frame. To enable this mode, set the `RMTEEN` bit in the **CAN IFn Message Control (CANIFnMCTL)** register. A matching received remote frame causes the `TXRQST` bit to be set, and the message object automatically transfers its data or generates an interrupt indicating a remote frame was requested. A remote frame can be strictly a single message identifier, or it can be a range of values specified in the message object. The CAN mask registers, **CANIFnMSKn**, configure which groups of frames are identified as remote frame requests. The `UMASK` bit in the **CANIFnMCTL** register enables the `MSK` bits in the **CANIFnMSKn** register to filter which frames are identified as a remote frame request. The `MXTD` bit in the **CANIFnMSK2** register should be set if a remote frame request is expected to be triggered by 29-bit extended identifiers.

23.3.3 Transmitting Message Objects

If the internal transmit shift register of the CAN module is ready for loading, and if a data transfer is not occurring between the CAN Interface Registers and message RAM, the valid message object with the highest priority that has a pending transmission request is loaded into the transmit shift register by the message handler and the transmission is started. The message object's `NEWDAT` bit in the **CANNWDAn** register is cleared. After a successful transmission, and if no new data was written to the message object since the start of the transmission, the `TXRQST` bit in the **CANTXRQn** register is cleared. If the CAN controller is configured to interrupt on a successful transmission of a message object, (the `TXIE` bit in the **CAN IFn Message Control (CANIFnMCTL)** register is set), the `INTPND` bit in the **CANIFnMCTL** register is set after a successful transmission. If the CAN module has lost the arbitration or if an error occurred during the transmission, the message is

re-transmitted as soon as the CAN bus is free again. If, meanwhile, the transmission of a message with higher priority has been requested, the messages are transmitted in the order of their priority.

23.3.4 Configuring a Transmit Message Object

The following steps illustrate how to configure a transmit message object.

1. In the **CAN IFn Command Mask (CANIFnCMASK)** register:
 - Set the `WRNRD` bit to specify a write to the **CANIFnCMASK** register; specify whether to transfer the `IDMASK`, `DIR`, and `MXTD` of the message object into the **CAN IFn** registers using the `MASK` bit
 - Specify whether to transfer the `ID`, `DIR`, `XTD`, and `MSGVAL` of the message object into the interface registers using the `ARB` bit
 - Specify whether to transfer the control bits into the interface registers using the `CONTROL` bit
 - Specify whether to clear the `INTPND` bit in the **CANIFnMCTL** register using the `CLRINTPND` bit
 - Specify whether to clear the `NEWDAT` bit in the **CANNWDAn** register using the `NEWDAT` bit
 - Specify which bits to transfer using the `DATAA` and `DATAB` bits
2. In the **CANIFnMSK1** register, use the `MSK[15:0]` bits to specify which of the bits in the 29-bit or 11-bit message identifier are used for acceptance filtering. Note that `MSK[15:0]` in this register are used for bits [15:0] of the 29-bit message identifier and are not used for an 11-bit identifier. A value of 0x00 enables all messages to pass through the acceptance filtering. Also note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the `UMASK` bit in the **CANIFnMCTL** register.
3. In the **CANIFnMSK2** register, use the `MSK[12:0]` bits to specify which of the bits in the 29-bit or 11-bit message identifier are used for acceptance filtering. Note that `MSK[12:0]` are used for bits [28:16] of the 29-bit message identifier; whereas `MSK[12:2]` are used for bits [10:0] of the 11-bit message identifier. Use the `MXTD` and `MDIR` bits to specify whether to use `XTD` and `DIR` for acceptance filtering. A value of 0x00 enables all messages to pass through the acceptance filtering. Also note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the `UMASK` bit in the **CANIFnMCTL** register.
4. For a 29-bit identifier, configure `ID[15:0]` in the **CANIFnARB1** register for bits [15:0] of the message identifier and `ID[12:0]` in the **CANIFnARB2** register for bits [28:16] of the message identifier. Set the `XTD` bit to indicate an extended identifier; set the `DIR` bit to indicate transmit; and set the `MSGVAL` bit to indicate that the message object is valid.
5. For an 11-bit identifier, disregard the **CANIFnARB1** register and configure `ID[12:2]` in the **CANIFnARB2** register for bits [10:0] of the message identifier. Clear the `XTD` bit to indicate a standard identifier; set the `DIR` bit to indicate transmit; and set the `MSGVAL` bit to indicate that the message object is valid.
6. In the **CANIFnMCTL** register:

- Optionally set the `UMASK` bit to enable the mask (`MSK`, `MXTD`, and `MDIR` specified in the **CANIFnMSK1** and **CANIFnMSK2** registers) for acceptance filtering
 - Optionally set the `TXIE` bit to enable the `INTPND` bit to be set after a successful transmission
 - Optionally set the `RMTEN` bit to enable the `TXRQST` bit to be set on the reception of a matching remote frame allowing automatic transmission
 - Set the `EOB` bit for a single message object
 - Configure the `DLC[3:0]` field to specify the size of the data frame. Take care during this configuration not to set the `NEWDAT`, `MSGLST`, `INTPND` or `TXRQST` bits.
7. Load the data to be transmitted into the **CAN IFn Data (CANIFnDA1, CANIFnDA2, CANIFnDB1, CANIFnDB2)** registers. Byte 0 of the CAN data frame is stored in `DATA[7:0]` in the **CANIFnDA1** register.
 8. Program the number of the message object to be transmitted in the `MNUM` field in the **CAN IFn Command Request (CANIFnCRQ)** register.
 9. When everything is properly configured, set the `TXRQST` bit in the **CANIFnMCTL** register. Once this bit is set, the message object is available to be transmitted, depending on priority and bus availability. Note that setting the `RMTEN` bit in the **CANIFnMCTL** register can also start message transmission if a matching remote frame has been received.

23.3.5 Updating a Transmit Message Object

The CPU may update the data bytes of a Transmit Message Object any time via the CAN Interface Registers and neither the `MSGVAL` bit in the **CANIFnARB2** register nor the `TXRQST` bits in the **CANIFnMCTL** register have to be cleared before the update.

Even if only some of the data bytes are to be updated, all four bytes of the corresponding **CANIFnDAn/CANIFnDBn** register have to be valid before the content of that register is transferred to the message object. Either the CPU must write all four bytes into the **CANIFnDAn/CANIFnDBn** register or the message object is transferred to the **CANIFnDAn/CANIFnDBn** register before the CPU writes the new data bytes.

In order to only update the data in a message object, the `WRNRD`, `DATAA` and `DATAB` bits in the **CANIFnMSKn** register are set, followed by writing the updated data into **CANIFnDA1**, **CANIFnDA2**, **CANIFnDB1**, and **CANIFnDB2** registers, and then the number of the message object is written to the `MNUM` field in the **CAN IFn Command Request (CANIFnCRQ)** register. To begin transmission of the new data as soon as possible, set the `TXRQST` bit in the **CANIFnMSKn** register.

To prevent the clearing of the `TXRQST` bit in the **CANIFnMCTL** register at the end of a transmission that may already be in progress while the data is updated, the `NEWDAT` and `TXRQST` bits have to be set at the same time in the **CANIFnMCTL** register. When these bits are set at the same time, `NEWDAT` is cleared as soon as the new transmission has started.

23.3.6 Accepting Received Message Objects

When the arbitration and control field (the `ID` and `XTD` bits in the **CANIFnARB2** and the `RMTEN` and `DLC[3:0]` bits of the **CANIFnMCTL** register) of an incoming message is completely shifted into the CAN controller, the message handling capability of the controller starts scanning the message RAM for a matching valid message object. To scan the message RAM for a matching message object, the controller uses the acceptance filtering programmed through the mask bits in the **CANIFnMSKn** register and enabled using the `UMASK` bit in the **CANIFnMCTL** register. Each valid

message object, starting with object 1, is compared with the incoming message to locate a matching message object in the message RAM. If a match occurs, the scanning is stopped and the message handler proceeds depending on whether it is a data frame or remote frame that was received.

23.3.7 Receiving a Data Frame

The message handler stores the message from the CAN controller receive shift register into the matching message object in the message RAM. The data bytes, all arbitration bits, and the DLC bits are all stored into the corresponding message object. In this manner, the data bytes are connected with the identifier even if arbitration masks are used. The NEWDAT bit of the CANIFnMCTL register is set to indicate that new data has been received. The CPU should clear this bit when it reads the message object to indicate to the controller that the message has been received, and the buffer is free to receive more messages. If the CAN controller receives a message and the NEWDAT bit is already set, the MSGLST bit in the CANIFnMCTL register is set to indicate that the previous data was lost. If the system requires an interrupt on successful reception of a frame, the RXIE bit of the CANIFnMCTL register should be set. In this case, the INTPND bit of the same register is set, causing the CANINT register to point to the message object that just received a message. The TXRQST bit of this message object should be cleared to prevent the transmission of a remote frame.

23.3.8 Receiving a Remote Frame

A remote frame contains no data, but instead specifies which object should be transmitted. When a remote frame is received, three different configurations of the matching message object have to be considered:

Table 23-2. Message Object Configurations

| Configuration in CANIFnMCTL | Description |
|--|---|
| <ul style="list-style-type: none"> ■ DIR = 1 (direction = transmit); programmed in the CANIFnARB2 register ■ RMTEN = 1 (set the TXRQST bit of the CANIFnMCTL register at reception of the frame to enable transmission) ■ UMASK = 1 or 0 | At the reception of a matching remote frame, the TXRQST bit of this message object is set. The rest of the message object remains unchanged, and the controller automatically transfers the data in the message object as soon as possible. |
| <ul style="list-style-type: none"> ■ DIR = 1 (direction = transmit); programmed in the CANIFnARB2 register ■ RMTEN = 0 (do not change the TXRQST bit of the CANIFnMCTL register at reception of the frame) ■ UMASK = 0 (ignore mask in the CANIFnMSKn register) | At the reception of a matching remote frame, the TXRQST bit of this message object remains unchanged, and the remote frame is ignored. This remote frame is disabled, the data is not transferred and nothing indicates that the remote frame ever happened. |
| <ul style="list-style-type: none"> ■ DIR = 1 (direction = transmit); programmed in the CANIFnARB2 register ■ RMTEN = 0 (do not change the TXRQST bit of the CANIFnMCTL register at reception of the frame) ■ UMASK = 1 (use mask (MSK, MXTD, and MDIR in the CANIFnMSKn register) for acceptance filtering) | At the reception of a matching remote frame, the TXRQST bit of this message object is cleared. The arbitration and control field (ID + XTD + RMTEN + DLC) from the shift register is stored into the message object in the message RAM, and the NEWDAT bit of this message object is set. The data field of the message object remains unchanged; the remote frame is treated similar to a received data frame. This mode is useful for a remote data request from another CAN device for which the TM4C129XKCZAD controller does not have readily available data. The software must fill the data and answer the frame manually. |

23.3.9 Receive/Transmit Priority

The receive/transmit priority for the message objects is controlled by the message number. Message object 1 has the highest priority, while message object 32 has the lowest priority. If more than one transmission request is pending, the message objects are transmitted in order based on the message object with the lowest message number. This prioritization is separate from that of the message identifier which is enforced by the CAN bus. As a result, if message object 1 and message object 2 both have valid messages to be transmitted, message object 1 is always transmitted first regardless of the message identifier in the message object itself.

23.3.10 Configuring a Receive Message Object

The following steps illustrate how to configure a receive message object.

1. Program the **CAN IFn Command Mask (CANIFnCMASK)** register as described in the “Configuring a Transmit Message Object” on page 1542 section, except that the WRNRD bit is set to specify a write to the message RAM.
2. Program the **CANIFnMSK1** and **CANIFnMSK2** registers as described in the “Configuring a Transmit Message Object” on page 1542 section to configure which bits are used for acceptance filtering. Note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the UMASK bit in the **CANIFnMCTL** register.
3. In the **CANIFnMSK2** register, use the MSK[12:0] bits to specify which of the bits in the 29-bit or 11-bit message identifier are used for acceptance filtering. Note that MSK[12:0] are used for bits [28:16] of the 29-bit message identifier; whereas MSK[12:2] are used for bits [10:0] of the 11-bit message identifier. Use the MXTD and MDIR bits to specify whether to use XTD and DIR for acceptance filtering. A value of 0x00 enables all messages to pass through the acceptance filtering. Also note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the UMASK bit in the **CANIFnMCTL** register.
4. Program the **CANIFnARB1** and **CANIFnARB2** registers as described in the “Configuring a Transmit Message Object” on page 1542 section to program XTD and ID bits for the message identifier to be received; set the MSGVAL bit to indicate a valid message; and clear the DIR bit to specify receive.
5. In the **CANIFnMCTL** register:
 - Optionally set the UMASK bit to enable the mask (MSK, MXTD, and MDIR specified in the **CANIFnMSK1** and **CANIFnMSK2** registers) for acceptance filtering
 - Optionally set the RXIE bit to enable the INTPND bit to be set after a successful reception
 - Clear the RMTEN bit to leave the TXRQST bit unchanged
 - Set the EOB bit for a single message object
 - Configure the DLC[3:0] field to specify the size of the data frame

Take care during this configuration not to set the NEWDAT, MSGLST, INTPND or TXRQST bits.
6. Program the number of the message object to be received in the MNUM field in the **CAN IFn Command Request (CANIFnCRQ)** register. Reception of the message object begins as soon as a matching frame is available on the CAN bus.

When the message handler stores a data frame in the message object, it stores the received Data Length Code and eight data bytes in the **CANIFnDA1**, **CANIFnDA2**, **CANIFnDB1**, and **CANIFnDB2** register. Byte 0 of the CAN data frame is stored in `DATA[7:0]` in the **CANIFnDA1** register. If the Data Length Code is less than 8, the remaining bytes of the message object are overwritten by unspecified values.

The CAN mask registers can be used to allow groups of data frames to be received by a message object. The CAN mask registers, **CANIFnMSKn**, configure which groups of frames are received by a message object. The `UMASK` bit in the **CANIFnMCTL** register enables the `MSK` bits in the **CANIFnMSKn** register to filter which frames are received. The `MXTD` bit in the **CANIFnMSK2** register should be set if only 29-bit extended identifiers are expected by this message object.

23.3.11 Handling of Received Message Objects

The CPU may read a received message any time via the CAN Interface registers because the data consistency is guaranteed by the message handler state machine.

Typically, the CPU first writes 0x007F to the **CANIFnCMSK** register and then writes the number of the message object to the **CANIFnCRQ** register. That combination transfers the whole received message from the message RAM into the Message Buffer registers (**CANIFnMSKn**, **CANIFnARBn**, and **CANIFnMCTL**). Additionally, the `NEWDAT` and `INTPND` bits are cleared in the message RAM, acknowledging that the message has been read and clearing the pending interrupt generated by this message object.

If the message object uses masks for acceptance filtering, the **CANIFnARBn** registers show the full, unmasked ID for the received message.

The `NEWDAT` bit in the **CANIFnMCTL** register shows whether a new message has been received since the last time this message object was read. The `MSGLST` bit in the **CANIFnMCTL** register shows whether more than one message has been received since the last time this message object was read. `MSGLST` is not automatically cleared, and should be cleared by software after reading its status.

Using a remote frame, the CPU may request new data from another CAN node on the CAN bus. Setting the `TXRQST` bit of a receive object causes the transmission of a remote frame with the receive object's identifier. This remote frame triggers the other CAN node to start the transmission of the matching data frame. If the matching data frame is received before the remote frame could be transmitted, the `TXRQST` bit is automatically reset. This prevents the possible loss of data when the other device on the CAN bus has already transmitted the data slightly earlier than expected.

23.3.11.1 Configuration of a FIFO Buffer

With the exception of the `EOB` bit in the **CANIFnMCTL** register, the configuration of receive message objects belonging to a FIFO buffer is the same as the configuration of a single receive message object (see “Configuring a Receive Message Object” on page 1545). To concatenate two or more message objects into a FIFO buffer, the identifiers and masks (if used) of these message objects have to be programmed to matching values. Due to the implicit priority of the message objects, the message object with the lowest message object number is the first message object in a FIFO buffer. The `EOB` bit of all message objects of a FIFO buffer except the last one must be cleared. The `EOB` bit of the last message object of a FIFO buffer is set, indicating it is the last entry in the buffer.

23.3.11.2 Reception of Messages with FIFO Buffers

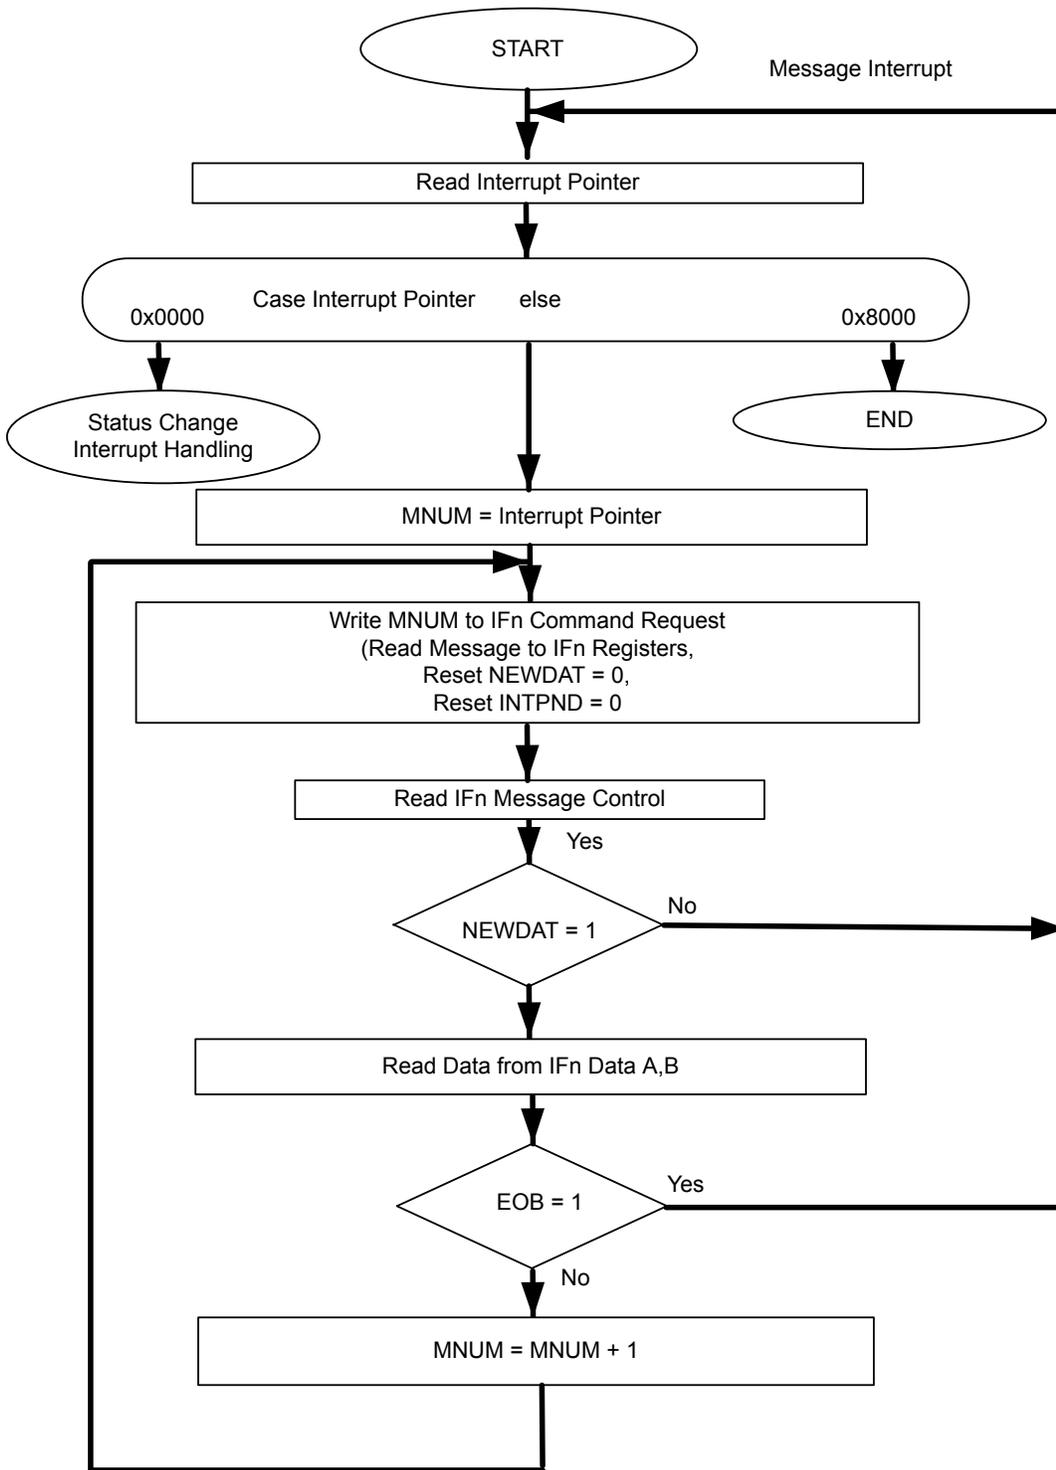

Received messages with identifiers matching to a FIFO buffer are stored starting with the message object with the lowest message number. When a message is stored into a message object of a FIFO buffer, the `NEWDAT` of the **CANIFnMCTL** register bit of this message object is set. By setting

NEWDAT while EOB is clear, the message object is locked and cannot be written to by the message handler until the CPU has cleared the NEWDAT bit. Messages are stored into a FIFO buffer until the last message object of this FIFO buffer is reached. Until all of the preceding message objects have been released by clearing the NEWDAT bit, all further messages for this FIFO buffer are written into the last message object of the FIFO buffer and therefore overwrite previous messages.

23.3.11.3 Reading from a FIFO Buffer

When the CPU transfers the contents of a message object from a FIFO buffer by writing its number to the **CANIFnCRQ** register, the **TXRQST** and **CLRINTPND** bits in the **CANIFnCMSK** register should be set such that the **NEWDAT** and **INTPEND** bits in the **CANIFnMCTL** register are cleared after the read. The values of these bits in the **CANIFnMCTL** register always reflect the status of the message object before the bits are cleared. To assure the correct function of a FIFO buffer, the CPU should read out the message objects starting with the message object with the lowest message number. When reading from the FIFO buffer, the user should be aware that a new received message is placed in the message object with the lowest message number for which the **NEWDAT** bit of the **CANIFnMCTL** register is clear. As a result, the order of the received messages in the FIFO is not guaranteed. Figure 23-3 on page 1548 shows how a set of message objects which are concatenated to a FIFO Buffer can be handled by the CPU.

Figure 23-3. Message Objects in a FIFO Buffer

23.3.12 Handling of Interrupts

If several interrupts are pending, the **CAN Interrupt (CANINT)** register points to the pending interrupt with the highest priority, disregarding their chronological order. The status interrupt has the highest

priority. Among the message interrupts, the message object's interrupt with the lowest message number has the highest priority. A message interrupt is cleared by clearing the message object's `INTPND` bit in the **CANIFnMCTL** register or by reading the **CAN Status (CANSTS)** register. The status Interrupt is cleared by reading the **CANSTS** register.

The interrupt identifier `INTID` in the **CANINT** register indicates the cause of the interrupt. When no interrupt is pending, the register reads as 0x0000. If the value of the `INTID` field is different from 0, then an interrupt is pending. If the `IE` bit is set in the **CANCTL** register, the interrupt line to the interrupt controller is active. The interrupt line remains active until the `INTID` field is 0, meaning that all interrupt sources have been cleared (the cause of the interrupt is reset), or until `IE` is cleared, which disables interrupts from the CAN controller.

The `INTID` field of the **CANINT** register points to the pending message interrupt with the highest interrupt priority. The `SIE` bit in the **CANCTL** register controls whether a change of the `RXOK`, `TXOK`, and `LEC` bits in the **CANSTS** register can cause an interrupt. The `EIE` bit in the **CANCTL** register controls whether a change of the `BOFF` and `EWARN` bits in the **CANSTS** register can cause an interrupt. The `IE` bit in the **CANCTL** register controls whether any interrupt from the CAN controller actually generates an interrupt to the interrupt controller. The **CANINT** register is updated even when the `IE` bit in the **CANCTL** register is clear, but the interrupt is not indicated to the CPU.

A value of 0x8000 in the **CANINT** register indicates that an interrupt is pending because the CAN module has updated, but not necessarily changed, the **CANSTS** register, indicating that either an error or status interrupt has been generated. A write access to the **CANSTS** register can clear the `RXOK`, `TXOK`, and `LEC` bits in that same register; however, the only way to clear the source of a status interrupt is to read the **CANSTS** register.

The source of an interrupt can be determined in two ways during interrupt handling. The first is to read the `INTID` bit in the **CANINT** register to determine the highest priority interrupt that is pending, and the second is to read the **CAN Message Interrupt Pending (CANMSGnINT)** register to see all of the message objects that have pending interrupts.

An interrupt service routine reading the message that is the source of the interrupt may read the message and clear the message object's `INTPND` bit at the same time by setting the `CLRINTPND` bit in the **CANIFnCMSK** register. Once the `INTPND` bit has been cleared, the **CANINT** register contains the message number for the next message object with a pending interrupt.

23.3.13 Test Mode

A Test Mode is provided which allows various diagnostics to be performed. Test Mode is entered by setting the `TEST` bit in the **CANCTL** register. Once in Test Mode, the `TX[1:0]`, `LBACK`, `SILENT` and `BASIC` bits in the **CAN Test (CANTST)** register can be used to put the CAN controller into the various diagnostic modes. The `RX` bit in the **CANTST** register allows monitoring of the `CANnRX` signal. All **CANTST** register functions are disabled when the `TEST` bit is cleared.

23.3.13.1 Silent Mode

Silent Mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits (Acknowledge Bits, Error Frames). The CAN Controller is put in Silent Mode setting the `SILENT` bit in the **CANTST** register. In Silent Mode, the CAN controller is able to receive valid data frames and valid remote frames, but it sends only recessive bits on the CAN bus and cannot start a transmission. If the CAN Controller is required to send a dominant bit (ACK bit, overload flag, or active error flag), the bit is rerouted internally so that the CAN Controller monitors this dominant bit, although the CAN bus remains in recessive state.

23.3.13.2 Loopback Mode

Loopback mode is useful for self-test functions. In Loopback Mode, the CAN Controller internally routes the `CANnTX` signal on to the `CANnRX` signal and treats its own transmitted messages as received messages and stores them (if they pass acceptance filtering) into the message buffer. The CAN Controller is put in Loopback Mode by setting the `LBACK` bit in the **CANTST** register. To be independent from external stimulation, the CAN Controller ignores acknowledge errors (a recessive bit sampled in the acknowledge slot of a data/remote frame) in Loopback Mode. The actual value of the `CANnRX` signal is disregarded by the CAN Controller. The transmitted messages can be monitored on the `CANnTX` signal.

23.3.13.3 Loopback Combined with Silent Mode

Loopback Mode and Silent Mode can be combined to allow the CAN Controller to be tested without affecting a running CAN system connected to the `CANnTX` and `CANnRX` signals. In this mode, the `CANnRX` signal is disconnected from the CAN Controller and the `CANnTX` signal is held recessive. This mode is enabled by setting both the `LBACK` and `SILENT` bits in the **CANTST** register.

23.3.13.4 Basic Mode

Basic Mode allows the CAN Controller to be operated without the Message RAM. In Basic Mode, The CANIF1 registers are used as the transmit buffer. The transmission of the contents of the IF1 registers is requested by setting the `BUSY` bit of the **CANIF1CRQ** register. The CANIF1 registers are locked while the `BUSY` bit is set. The `BUSY` bit indicates that a transmission is pending. As soon the CAN bus is idle, the CANIF1 registers are loaded into the shift register of the CAN Controller and transmission is started. When the transmission has completed, the `BUSY` bit is cleared and the locked CANIF1 registers are released. A pending transmission can be aborted at any time by clearing the `BUSY` bit in the **CANIF1CRQ** register while the CANIF1 registers are locked. If the CPU has cleared the `BUSY` bit, a possible retransmission in case of lost arbitration or an error is disabled.

The CANIF2 Registers are used as a receive buffer. After the reception of a message, the contents of the shift register are stored in the CANIF2 registers, without any acceptance filtering. Additionally, the actual contents of the shift register can be monitored during the message transfer. Each time a read message object is initiated by setting the `BUSY` bit of the **CANIF2CRQ** register, the contents of the shift register are stored into the CANIF2 registers.

In Basic Mode, all message-object-related control and status bits and of the control bits of the **CANIFnCMSK** registers are not evaluated. The message number of the **CANIFnCRQ** registers is also not evaluated. In the **CANIF2MCTL** register, the `NEWDAT` and `MSGLST` bits retain their function, the `DLC[3:0]` field shows the received DLC, the other control bits are cleared.

Basic Mode is enabled by setting the `BASIC` bit in the **CANTST** register.

23.3.13.5 Transmit Control

Software can directly override control of the `CANnTX` signal in four different ways.

- `CANnTX` is controlled by the CAN Controller
- The sample point is driven on the `CANnTX` signal to monitor the bit timing
- `CANnTX` drives a low value
- `CANnTX` drives a high value

The last two functions, combined with the readable CAN receive pin CAN_nRX , can be used to check the physical layer of the CAN bus.

The Transmit Control function is enabled by programming the $TX[1:0]$ field in the **CANTST** register. The three test functions for the CAN_nTX signal interfere with all CAN protocol functions. $TX[1:0]$ must be cleared when CAN message transfer or Loopback Mode, Silent Mode, or Basic Mode are selected.

23.3.14 Bit Timing Configuration Error Considerations

Even if minor errors in the configuration of the CAN bit timing do not result in immediate failure, the performance of a CAN network can be reduced significantly. In many cases, the CAN bit synchronization amends a faulty configuration of the CAN bit timing to such a degree that only occasionally an error frame is generated. In the case of arbitration, however, when two or more CAN nodes simultaneously try to transmit a frame, a misplaced sample point may cause one of the transmitters to become error passive. The analysis of such sporadic errors requires a detailed knowledge of the CAN bit synchronization inside a CAN node and of the CAN nodes' interaction on the CAN bus.

23.3.15 Bit Time and Bit Rate

The CAN system supports bit rates in the range of lower than 1 Kbps up to 1000 Kbps. Each member of the CAN network has its own clock generator. The timing parameter of the bit time can be configured individually for each CAN node, creating a common bit rate even though the CAN nodes' oscillator periods may be different.

Because of small variations in frequency caused by changes in temperature or voltage and by deteriorating components, these oscillators are not absolutely stable. As long as the variations remain inside a specific oscillator's tolerance range, the CAN nodes are able to compensate for the different bit rates by periodically resynchronizing to the bit stream.

According to the CAN specification, the bit time is divided into four segments (see Figure 23-4 on page 1552): the Synchronization Segment, the Propagation Time Segment, the Phase Buffer Segment 1, and the Phase Buffer Segment 2. Each segment consists of a specific, programmable number of time quanta (see Table 23-3 on page 1552). The length of the time quantum (t_q), which is the basic time unit of the bit time, is defined by the CAN controller's input clock (f_{sys}) and the Baud Rate Prescaler (**BRP**):

$$t_q = BRP / f_{sys}$$

The f_{sys} input clock is the system clock frequency as configured by the **RSCLKCFG** register (see page 287).

The Synchronization Segment Sync is that part of the bit time where edges of the CAN bus level are expected to occur; the distance between an edge that occurs outside of $Sync$ and the $Sync$ is called the phase error of that edge.

The Propagation Time Segment Prop is intended to compensate for the physical delay times within the CAN network.

The Phase Buffer Segments Phase1 and Phase2 surround the Sample Point.

The (Re-)Synchronization Jump Width (SJW) defines how far a resynchronization may move the Sample Point inside the limits defined by the Phase Buffer Segments to compensate for edge phase errors.

A given bit rate may be met by different bit-time configurations, but for the proper function of the CAN network, the physical delay times and the oscillator's tolerance range have to be considered.

Figure 23-4. CAN Bit Time

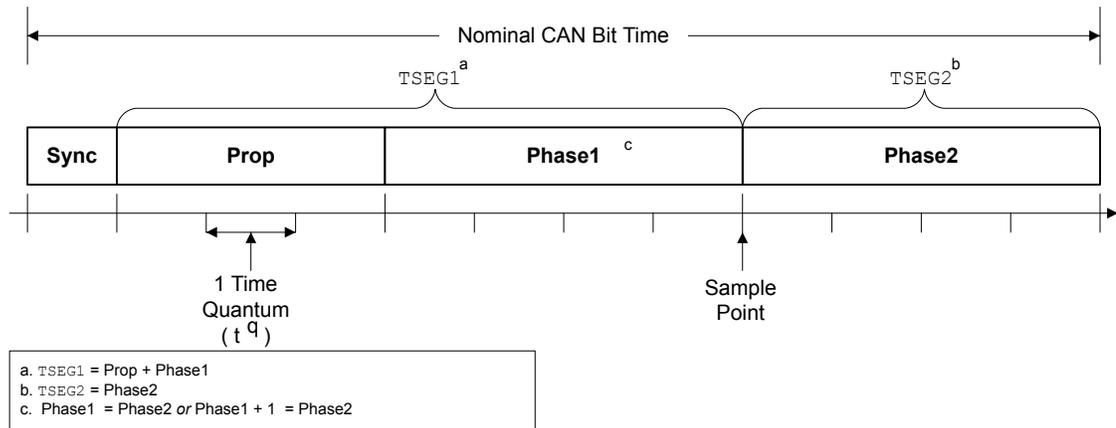

Table 23-3. CAN Protocol Ranges^a

| Parameter | Range | Remark |
|-----------|-------------------------|--|
| BRP | [1 .. 64] | Defines the length of the time quantum t _q . The CANBRPE register can be used to extend the range to 1024. |
| Sync | 1 t _q | Fixed length, synchronization of bus input to system clock |
| Prop | [1 .. 8] t _q | Compensates for the physical delay times |
| Phase1 | [1 .. 8] t _q | May be lengthened temporarily by synchronization |
| Phase2 | [1 .. 8] t _q | May be shortened temporarily by synchronization |
| SJW | [1 .. 4] t _q | May not be longer than either Phase Buffer Segment |

a. This table describes the minimum programmable ranges required by the CAN protocol.

The bit timing configuration is programmed in two register bytes in the **CANBIT** register. In the **CANBIT** register, the four components TSEG2, TSEG1, SJW, and BRP have to be programmed to a numerical value that is one less than its functional value; so instead of values in the range of [1..n], values in the range of [0..n-1] are programmed. That way, for example, SJW (functional range of [1..4]) is represented by only two bits in the SJW bit field. Table 23-4 shows the relationship between the **CANBIT** register values and the parameters.

Table 23-4. CANBIT Register Values

| CANBIT Register Field | Setting |
|-----------------------|-------------------|
| TSEG2 | Phase2 - 1 |
| TSEG1 | Prop + Phase1 - 1 |
| SJW | SJW - 1 |
| BRP | BRP |

Therefore, the length of the bit time is (programmed values):

$$[TSEG1 + TSEG2 + 3] \times t_q$$

or (functional values):

$$[Sync + Prop + Phase1 + Phase2] \times t_q$$

The data in the **CANBIT** register is the configuration input of the CAN protocol controller. The baud rate prescaler (configured by the BRP field) defines the length of the time quantum, the basic time

unit of the bit time; the bit timing logic (configured by TSEG1, TSEG2, and SJW) defines the number of time quanta in the bit time.

The processing of the bit time, the calculation of the position of the sample point, and occasional synchronizations are controlled by the CAN controller and are evaluated once per time quantum.

The CAN controller translates messages to and from frames. In addition, the controller generates and discards the enclosing fixed format bits, inserts and extracts stuff bits, calculates and checks the CRC code, performs the error management, and decides which type of synchronization is to be used. The bit value is received or transmitted at the sample point. The information processing time (IPT) is the time after the sample point needed to calculate the next bit to be transmitted on the CAN bus. The IPT includes any of the following: retrieving the next data bit, handling a CRC bit, determining if bit stuffing is required, generating an error flag or simply going idle.

The IPT is application-specific but may not be longer than $2 t_q$; the CAN's IPT is $0 t_q$. Its length is the lower limit of the programmed length of Phase2. In case of synchronization, Phase2 may be shortened to a value less than IPT, which does not affect bus timing.

23.3.16 Calculating the Bit Timing Parameters

Usually, the calculation of the bit timing configuration starts with a required bit rate or bit time. The resulting bit time (1/bit rate) must be an integer multiple of the system clock period.

The bit time may consist of 4 to 25 time quanta. Several combinations may lead to the required bit time, allowing iterations of the following steps.

The first part of the bit time to be defined is Prop. Its length depends on the delay times measured in the system. A maximum bus length as well as a maximum node delay has to be defined for expandable CAN bus systems. The resulting time for Prop is converted into time quanta (rounded up to the nearest integer multiple of t_q).

Sync is $1 t_q$ long (fixed), which leaves $(\text{bit time} - \text{Prop} - 1) t_q$ for the two Phase Buffer Segments. If the number of remaining t_q is even, the Phase Buffer Segments have the same length, that is, $\text{Phase2} = \text{Phase1}$, else $\text{Phase2} = \text{Phase1} + 1$.

The minimum nominal length of Phase2 has to be regarded as well. Phase2 may not be shorter than the CAN controller's Information Processing Time, which is, depending on the actual implementation, in the range of $[0..2] t_q$.

The length of the synchronization jump width is set to the least of 4, Phase1 or Phase2.

The oscillator tolerance range necessary for the resulting configuration is calculated by the formula given below:

$$(1 - df) \times f_{nom} \leq f_{osc} \leq (1 + df) \times f_{nom}$$

where:

- df = Maximum tolerance of oscillator frequency
- f_{osc} = Actual oscillator frequency
- f_{nom} = Nominal oscillator frequency

Maximum frequency tolerance must take into account the following formulas:

$$df \leq \frac{(Phase_seg1, Phase_seg2) \min}{2 \times (13 \times t_{bit} - Phase_Seg2)}$$

$$df \max = 2 \times df \times f_{nom}$$

where:

- Phase1 and Phase2 are from Table 23-3 on page 1552
- tbit = Bit Time
- dfmax = Maximum difference between two oscillators

If more than one configuration is possible, that configuration allowing the highest oscillator tolerance range should be chosen.

CAN nodes with different system clocks require different configurations to come to the same bit rate. The calculation of the propagation time in the CAN network, based on the nodes with the longest delay times, is done once for the whole network.

The CAN system's oscillator tolerance range is limited by the node with the lowest tolerance range.

The calculation may show that bus length or bit rate have to be decreased or that the oscillator frequencies' stability has to be increased in order to find a protocol-compliant configuration of the CAN bit timing.

23.3.16.1 Example for Bit Timing at High Baud Rate

In this example, the frequency of CAN clock is 25 MHz, and the bit rate is 1 Mbps.

$$\text{bit time} = 1 \mu\text{s} = n * t_q = 5 * t_q$$

$$t_q = 200 \text{ ns}$$

$$t_q = (\text{Baud rate Prescaler}) / \text{CAN Clock}$$

$$\text{Baud rate Prescaler} = t_q * \text{CAN Clock}$$

$$\text{Baud rate Prescaler} = 200\text{E}-9 * 25\text{E}6 = 5$$

$$t_{\text{Sync}} = 1 * t_q = 200 \text{ ns}$$

\\fixed at 1 time quanta

delay of bus driver 50 ns

delay of receiver circuit 30 ns

delay of bus line (40m) 220 ns

$$t_{\text{Prop}} 400 \text{ ns} = 2 * t_q$$

\\400 is next integer multiple of t_q

$$\text{bit time} = t_{\text{Sync}} + t_{\text{TSeg1}} + t_{\text{TSeg2}} = 5 * t_q$$

$$\text{bit time} = t_{\text{Sync}} + t_{\text{Prop}} + t_{\text{Phase 1}} + t_{\text{Phase 2}}$$

$$t_{\text{Phase 1}} + t_{\text{Phase 2}} = \text{bit time} - t_{\text{Sync}} - t_{\text{Prop}}$$

$$t_{\text{Phase 1}} + t_{\text{Phase 2}} = (5 * t_q) - (1 * t_q) - (2 * t_q)$$

$$t_{\text{Phase 1}} + t_{\text{Phase 2}} = 2 * t_q$$

$$t_{\text{Phase1}} = 1 * t_q$$

$$t_{\text{Phase2}} = 1 * t_q$$

\\tPhase2 = tPhase1

```

tTSeg1 = tProp + tPhase1
tTSeg1 = (2 * tq) + (1 * tq)
tTSeg1 = 3 * tq

tTSeg2 = tPhase2
tTSeg2 = (Information Processing Time + 1) * tq
tTSeg2 = 1 * tq                \\Assumes IPT=0

tSJW = 1 * tq                \\Least of 4, Phase1 and Phase2

```

In the above example, the bit field values for the **CANBIT** register are:

| | |
|-------|---|
| TSEG2 | = TSeg2 -1 = 1-1 = 0 |
| TSEG1 | = TSeg1 -1 = 3-1 = 2 |
| SJW | = SJW -1 = 1-1 = 0 |
| BRP | = Baud rate prescaler - 1 = 5-1 = 4 |

The final value programmed into the **CANBIT** register = 0x0204.

23.3.16.2 Example for Bit Timing at Low Baud Rate

In this example, the frequency of the CAN clock is 50 MHz, and the bit rate is 100 Kbps.

```

bit time = 10 μs = n * tq = 10 * tq
tq = 1 μs
tq = (Baud rate Prescaler)/CAN Clock
Baud rate Prescaler = tq * CAN Clock
Baud rate Prescaler = 1E-6 * 50E6 = 50

tSync = 1 * tq = 1 μs                \\fixed at 1 time quanta

delay of bus driver 200 ns
delay of receiver circuit 80 ns
delay of bus line (40m) 220 ns
tProp 1 μs = 1 * tq                \\1 μs is next integer multiple of tq

bit time = tSync + tTSeg1 + tTSeg2 = 10 * tq
bit time = tSync + tProp + tPhase 1 + tPhase2
tPhase 1 + tPhase2 = bit time - tSync - tProp
tPhase 1 + tPhase2 = (10 * tq) - (1 * tq) - (1 * tq)
tPhase 1 + tPhase2 = 8 * tq
tPhase1 = 4 * tq
tPhase2 = 4 * tq                \\tPhase1 = tPhase2

```

$$\begin{aligned}
 tTSeg1 &= tProp + tPhase1 \\
 tTSeg1 &= (1 * t_q) + (4 * t_q) \\
 tTSeg1 &= 5 * t_q \\
 tTSeg2 &= tPhase2 \\
 tTSeg2 &= (Information Processing Time + 4) * t_q \\
 tTSeg2 &= 4 * t_q \qquad \qquad \qquad \backslash\backslash \text{Assumes IPT}=0 \\
 \\
 tSJW &= 4 * t_q \qquad \qquad \qquad \backslash\backslash \text{Least of 4, Phase1, and Phase2}
 \end{aligned}$$

| | |
|-------|--|
| TSEG2 | = TSeg2 -1 = 4-1 = 3 |
| TSEG1 | = TSeg1 -1 = 5-1 = 4 |
| SJW | = SJW -1 = 4-1 = 3 |
| BRP | = Baud rate prescaler - 1 = 50-1 =49 |

The final value programmed into the **CANBIT** register = 0x34F1.

23.4 Register Map

Table 23-5 on page 1556 lists the registers. All addresses given are relative to the CAN base address of:

- CAN0: 0x4004.0000
- CAN1: 0x4004.1000

Note that the CAN controller clock must be enabled before the registers can be programmed (see page 412). There must be a delay of 3 system clocks after the CAN module clock is enabled before any CAN module registers are accessed.

Table 23-5. CAN Register Map

| Offset | Name | Type | Reset | Description | See page |
|--------|-----------|------|-------------|-----------------------------------|----------|
| 0x000 | CANCTL | RW | 0x0000.0001 | CAN Control | 1559 |

23.5 CAN Register Descriptions

The remainder of this section lists and describes the CAN registers, in numerical order by address offset. There are two sets of Interface Registers that are used to access the Message Objects in

the Message RAM: **CANIF1x** and **CANIF2x**. The function of the two sets are identical and are used to queue transactions.

Register 1: CAN Control (CANCTL), offset 0x000

This control register initializes the module and enables test mode and interrupts.

The bus-off recovery sequence (see CAN Specification Rev. 2.0) cannot be shortened by setting or clearing `INIT`. If the device goes bus-off, it sets `INIT`, stopping all bus activities. Once `INIT` has been cleared by the CPU, the device then waits for 129 occurrences of Bus Idle (129 * 11 consecutive High bits) before resuming normal operations. At the end of the bus-off recovery sequence, the Error Management Counters are reset.

During the waiting time after `INIT` is cleared, each time a sequence of 11 High bits has been monitored, a `BITERROR0` code is written to the `CANSTS` register (the `LEC` field = 0x5), enabling the CPU to readily check whether the CAN bus is stuck Low or continuously disturbed, and to monitor the proceeding of the bus-off recovery sequence.

| 0 | Normal operation. | | | | | | | | | |
| 1 | Initialization started. | | | | | | | | | |

Register 2: CAN Status (CANSTS), offset 0x004

Important: This register is read-sensitive. See the register description for details.

The status register contains information for interrupt servicing such as Bus-Off, error count threshold, and error types.

The LEC field holds the code that indicates the type of the last error to occur on the CAN bus. This field is cleared when a message has been transferred (reception or transmission) without error. The unused error code 0x7 may be written by the CPU to manually set this field to an invalid error so that it can be checked for a change later.

An error interrupt is generated by the BOFF and EWARN bits, and a status interrupt is generated by the RXOK, TXOK, and LEC bits, if the corresponding enable bits in the **CAN Control (CANCTL)** register are set. A change of the EPASS bit or a write to the RXOK, TXOK, or LEC bits does not generate an interrupt.

Reading the **CAN Status (CANSTS)** register clears the **CAN Interrupt (CANINT)** register, if it is pending.

CAN Status (CANSTS)

| 0x1 | Stuff Error | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| | More than 5 equal bits in a sequence have occurred in a part of a received message where this is not allowed. | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 0x2 | Format Error | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| | A fixed format part of the received frame has the wrong format. | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 0x3 | ACK Error | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| | The message transmitted was not acknowledged by another node. | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 0x4 | Bit 1 Error | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| | When a message is transmitted, the CAN controller monitors the data lines to detect any conflicts. When the arbitration field is transmitted, data conflicts are a part of the arbitration protocol. When other frame fields are transmitted, data conflicts are considered errors. | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| | A Bit 1 Error indicates that the device wanted to send a High level (logical 1) but the monitored bus value was Low (logical 0). | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 0x5 | Bit 0 Error | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| | A Bit 0 Error indicates that the device wanted to send a Low level (logical 0), but the monitored bus value was High (logical 1). | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| | During bus-off recovery, this status is set each time a sequence of 11 High bits has been monitored. By checking for this status, software can monitor the proceeding of the bus-off recovery sequence without any disturbances to the bus. | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 0x6 | CRC Error | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| | The CRC checksum was incorrect in the received message, indicating that the calculated value received did not match the calculated CRC of the data. | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 0x7 | No Event | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| | When the LEC bit shows this value, no CAN bus event was detected since this value was written to the LEC field. | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

Register 3: CAN Error Counter (CANERR), offset 0x008

This register contains the error counter values, which can be used to analyze the cause of an error.

CAN Error Counter (CANERR)

CAN0 base: 0x4004.0000
 CAN1 base: 0x4004.1000
 Offset 0x008
 Type RO, reset 0x0000.0000

| Bit/Field | Name | Type | Reset | Description | | | | | | |
|-----------|---|------|--------|--|-------|-------------|---|---|---|---|
| 31:16 | reserved | RO | 0x0000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. | | | | | | |
| 15 | RP | RO | 0 | Received Error Passive | | | | | | |
| | | | | <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>The Receive Error counter is below the Error Passive level (127 or less).</td> </tr> <tr> <td>1</td> <td>The Receive Error counter has reached the Error Passive level (128 or greater).</td> </tr> </tbody> </table> | Value | Description | 0 | The Receive Error counter is below the Error Passive level (127 or less). | 1 | The Receive Error counter has reached the Error Passive level (128 or greater). |
| Value | Description | | | | | | | | | |
| 0 | The Receive Error counter is below the Error Passive level (127 or less). | | | | | | | | | |
| 1 | The Receive Error counter has reached the Error Passive level (128 or greater). | | | | | | | | | |
| 14:8 | REC | RO | 0x00 | Receive Error Counter This field contains the state of the receiver error counter (0 to 127). | | | | | | |
| 7:0 | TEC | RO | 0x00 | Transmit Error Counter This field contains the state of the transmit error counter (0 to 255). | | | | | | |

Register 4: CAN Bit Timing (CANBIT), offset 0x00C

This register is used to program the bit width and bit quantum. Values are programmed to the system clock frequency. This register is write-enabled by setting the `CCE` and `INIT` bits in the `CANCTL` register. See “Bit Time and Bit Rate” on page 1551 for more information.

CAN Bit Timing (CANBIT)

CAN0 base: 0x4004.0000
CAN1 base: 0x4004.1000
Offset 0x00C
Type RW, reset 0x0000.2301

| | | | | | | | | | | | | | | | | |
|-------|----------|-------|----|----|-------|----|----|----|-----|----|-----|----|----|----|----|----|
| | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | reserved | | | | | | | | | | | | | | | |
| Type | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | reserved | TSEG2 | | | TSEG1 | | | | SJW | | BRP | | | | | |
| Type | RO | RW | RW | RW | RW | RW | RW | RW | RW | RW | RW | RW | RW | RW | RW | RW |
| Reset | 0 | 0 | 1 | 0 | 0 | 0 | 1 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 |

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|--------|--|
| 31:15 | reserved | RO | 0x0000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 14:12 | TSEG2 | RW | 0x2 | Time Segment after Sample Point 0x00-0x07: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used. So, for example, the reset value of 0x2 means that 3 (2+1) bit time quanta are defined for <code>Phase2</code> (see Figure 23-4 on page 1552). The bit time quanta is defined by the <code>BRP</code> field. |
| 11:8 | TSEG1 | RW | 0x3 | Time Segment Before Sample Point 0x00-0x0F: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used. So, for example, the reset value of 0x3 means that 4 (3+1) bit time quanta are defined for <code>Phase1</code> (see Figure 23-4 on page 1552). The bit time quanta is defined by the <code>BRP</code> field. |
| 7:6 | SJW | RW | 0x0 | (Re)Synchronization Jump Width 0x00-0x03: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used. During the start of frame (SOF), if the CAN controller detects a phase error (misalignment), it can adjust the length of <code>TSEG2</code> or <code>TSEG1</code> by the value in <code>SJW</code> . So the reset value of 0 adjusts the length by 1 bit time quanta. |
| 5:0 | BRP | RW | 0x1 | Baud Rate Prescaler The value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quantum. 0x00-0x03F: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used. <code>BRP</code> defines the number of CAN clock periods that make up 1 bit time quanta, so the reset value is 2 bit time quanta (1+1). The <code>CANBRPE</code> register can be used to further divide the bit time. |

Register 5: CAN Interrupt (CANINT), offset 0x010

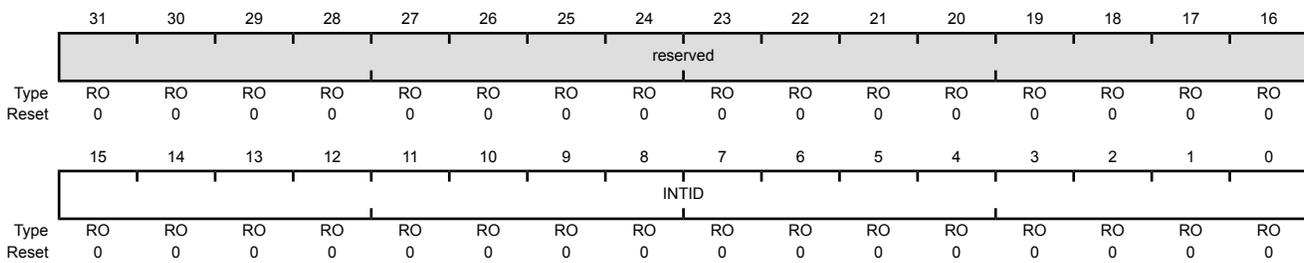

This register indicates the source of the interrupt.

If several interrupts are pending, the **CAN Interrupt (CANINT)** register points to the pending interrupt with the highest priority, disregarding the order in which the interrupts occurred. An interrupt remains pending until the CPU has cleared it. If the **INTID** field is not 0x0000 (the default) and the **IE** bit in the **CANCTL** register is set, the interrupt is active. The interrupt line remains active until the **INTID** field is cleared by reading the **CANSTS** register, or until the **IE** bit in the **CANCTL** register is cleared.

Note: Reading the **CAN Status (CANSTS)** register clears the **CAN Interrupt (CANINT)** register, if it is pending.

CAN Interrupt (CANINT)

Register 6: CAN Test (CANTST), offset 0x014

This register is used for self-test and external pin access. It is write-enabled by setting the `TEST` bit in the `CANCTL` register. Different test functions may be combined, however, CAN transfers are affected if the `TX` bits in this register are not zero.

Register 8: CAN IF1 Command Request (CANIF1CRQ), offset 0x020

Register 9: CAN IF2 Command Request (CANIF2CRQ), offset 0x080

A message transfer is started as soon as there is a write of the message object number to the MNUM field when the TXRQST bit in the CANIF1MCTL register is set. With this write operation, the BUSY bit is automatically set to indicate that a transfer between the CAN Interface Registers and the internal message RAM is in progress. After a wait time of 3 to 6 CAN_CLK periods, the transfer between the interface register and the message RAM completes, which then clears the BUSY bit.

CAN IFn Command Request (CANIFnCRQ)

Register 10: CAN IF1 Command Mask (CANIF1CMSK), offset 0x024**Register 11: CAN IF2 Command Mask (CANIF2CMSK), offset 0x084**

Reading the Command Mask registers provides status for various functions. Writing to the Command Mask registers specifies the transfer direction and selects which buffer registers are the source or target of the data transfer.

Note that when a read from the message object buffer occurs when the WRNRD bit is clear and the CLRINTPND and/or NEWDAT bits are set, the interrupt pending and/or new data flags in the message object buffer are cleared.

Register 12: CAN IF1 Mask 1 (CANIF1MSK1), offset 0x028

Register 13: CAN IF2 Mask 1 (CANIF2MSK1), offset 0x088

The mask information provided in this register accompanies the data (**CANIFnDAn**), arbitration information (**CANIFnARBn**), and control information (**CANIFnMCTL**) to the message object in the message RAM. The mask is used with the **ID** bit in the **CANIFnARBn** register for acceptance filtering. Additional mask information is contained in the **CANIFnMSK2** register.

CAN IFn Mask 1 (CANIFnMSK1)

CAN0 base: 0x4004.0000
 CAN1 base: 0x4004.1000
 Offset 0x028
 Type RW, reset 0x0000.FFFF

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|--------|--|
| 31:16 | reserved | RO | 0x0000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 15:0 | MSK | RW | 0xFFFF | Identifier Mask When using a 29-bit identifier, these bits are used for bits [15:0] of the ID. The MSK field in the CANIFnMSK2 register are used for bits [28:16] of the ID. When using an 11-bit identifier, these bits are ignored. |
| | | | | Value Description |
| | | | | 0 The corresponding identifier field (ID) in the message object cannot inhibit the match in acceptance filtering. |
| | | | | 1 The corresponding identifier field (ID) is used for acceptance filtering. |

Register 14: CAN IF1 Mask 2 (CANIF1MSK2), offset 0x02C**Register 15: CAN IF2 Mask 2 (CANIF2MSK2), offset 0x08C**

This register holds extended mask information that accompanies the **CANIFnMSK1** register.

CAN IFn Mask 2 (CANIFnMSK2)

CAN0 base: 0x4004.0000

| 15:0 | DATA | RW | 0x0000 | Data The CANIFnDA1 registers contain data bytes 1 and 0; CANIFnDA2 data bytes 3 and 2; CANIFnDB1 data bytes 5 and 4; and CANIFnDB2 data bytes 7 and 6. |

Register 30: CAN Transmission Request 1 (CANTXRQ1), offset 0x100

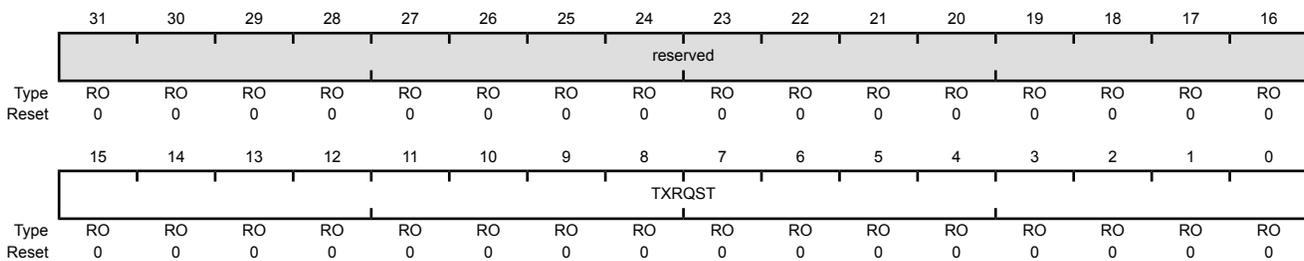

Register 31: CAN Transmission Request 2 (CANTXRQ2), offset 0x104

The **CANTXRQ1** and **CANTXRQ2** registers hold the **TXRQST** bits of the 32 message objects. By reading out these bits, the CPU can check which message object has a transmission request pending. The **TXRQST** bit of a specific message object can be changed by three sources: (1) the CPU via the **CANIFnMCTL** register, (2) the message handler state machine after the reception of a remote frame, or (3) the message handler state machine after a successful transmission.

The **CANTXRQ1** register contains the **TXRQST** bits of the first 16 message objects in the message RAM; the **CANTXRQ2** register contains the **TXRQST** bits of the second 16 message objects.

CAN Transmission Request n (CANTXRQn)

CAN0 base: 0x4004.0000
 CAN1 base: 0x4004.1000

| 15:0 | TXRQST | RO | 0x0000 | Transmission Request Bits |
| | | | | Value Description |
| | | | | 0 The corresponding message object is not waiting for transmission. |
| | | | | 1 The transmission of the corresponding message object is requested and is not yet done. |

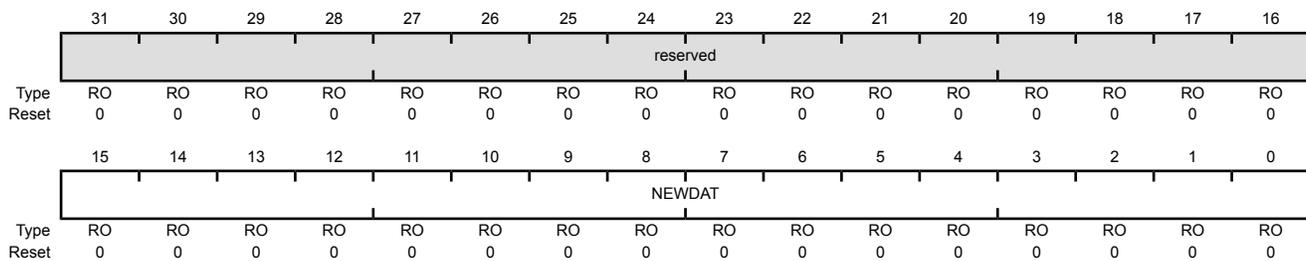

Register 32: CAN New Data 1 (CANNWDA1), offset 0x120**Register 33: CAN New Data 2 (CANNWDA2), offset 0x124**

The **CANNWDA1** and **CANNWDA2** registers hold the **NEWDAT** bits of the 32 message objects. By reading these bits, the CPU can check which message object has its data portion updated. The **NEWDAT** bit of a specific message object can be changed by three sources: (1) the CPU via the **CANIFnMCTL** register, (2) the message handler state machine after the reception of a data frame, or (3) the message handler state machine after a successful transmission.

The **CANNWDA1** register contains the **NEWDAT** bits of the first 16 message objects in the message RAM; the **CANNWDA2** register contains the **NEWDAT** bits of the second 16 message objects.

CAN New Data n (CANNWDAn)

CAN0 base: 0x4004.0000
 CAN1 base: 0x4004.1000
 Offset 0x120
 Type RO, reset 0x0000.0000

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|--------|---|
| 31:16 | reserved | RO | 0x0000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 15:0 | NEWDAT | RO | 0x0000 | New Data Bits |
| | | | | Value Description |
| | | | | 0 No new data has been written into the data portion of the corresponding message object by the message handler since the last time this flag was cleared by the CPU. |
| | | | | 1 The message handler or the CPU has written new data into the data portion of the corresponding message object. |

Register 34: CAN Message 1 Interrupt Pending (CANMSG1INT), offset 0x140

Register 35: CAN Message 2 Interrupt Pending (CANMSG2INT), offset 0x144

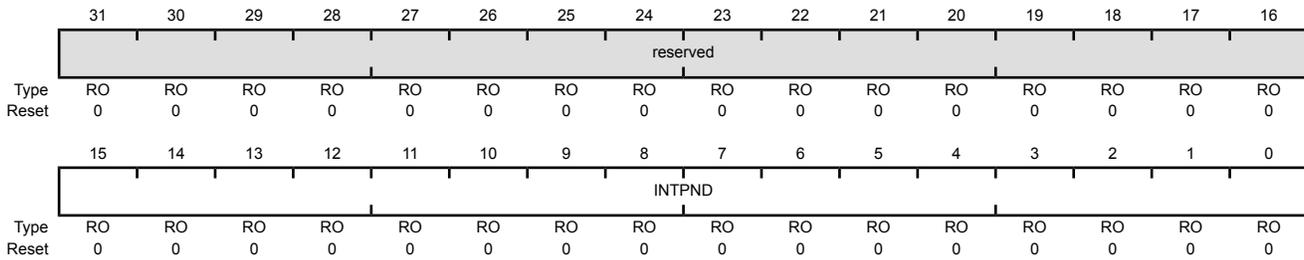

The **CANMSG1INT** and **CANMSG2INT** registers hold the **INTPND** bits of the 32 message objects. By reading these bits, the CPU can check which message object has an interrupt pending. The **INTPND** bit of a specific message object can be changed through two sources: (1) the CPU via the **CANIFnMCTL** register, or (2) the message handler state machine after the reception or transmission of a frame.

This field is also encoded in the **CANINT** register.

The **CANMSG1INT** register contains the **INTPND** bits of the first 16 message objects in the message RAM; the **CANMSG2INT** register contains the **INTPND** bits of the second 16 message objects.

CAN Message n Interrupt Pending (CANMSGnINT)

CAN0 base: 0x4004.0000
 CAN1 base: 0x4004.1000

| 15:0 | INTPND | RO | 0x0000 | Interrupt Pending Bits |
| | | | Value | Description |
| | | | 0 | The corresponding message object is not the source of an interrupt. |
| | | | 1 | The corresponding message object is the source of an interrupt. |

Register 36: CAN Message 1 Valid (CANMSG1VAL), offset 0x160**Register 37: CAN Message 2 Valid (CANMSG2VAL), offset 0x164**

The **CANMSG1VAL** and **CANMSG2VAL** registers hold the **MSGVAL** bits of the 32 message objects. By reading these bits, the CPU can check which message object is valid. The message valid bit of a specific message object can be changed with the **CANIFnARB2** register.

The **CANMSG1VAL** register contains the **MSGVAL** bits of the first 16 message objects in the message RAM; the **CANMSG2VAL** register contains the **MSGVAL** bits of the second 16 message objects in the message RAM.

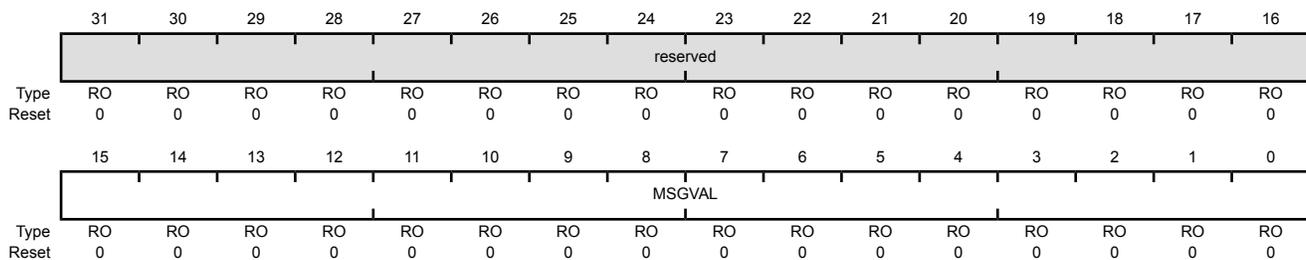

CAN Message n Valid (CANMSGnVAL)

CAN0 base: 0x4004.0000

CAN1 base: 0x4004.1000

Offset 0x160

Type RO, reset 0x0000.0000

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|--------|---|
| 31:16 | reserved | RO | 0x0000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 15:0 | MSGVAL | RO | 0x0000 | Message Valid Bits |
| | | | | Value Description |
| | | | | 0 The corresponding message object is not configured and is ignored by the message handler. |
| | | | | 1 The corresponding message object is configured and should be considered by the message handler. |

24 Ethernet Controller

The Ethernet Controller has the following features:

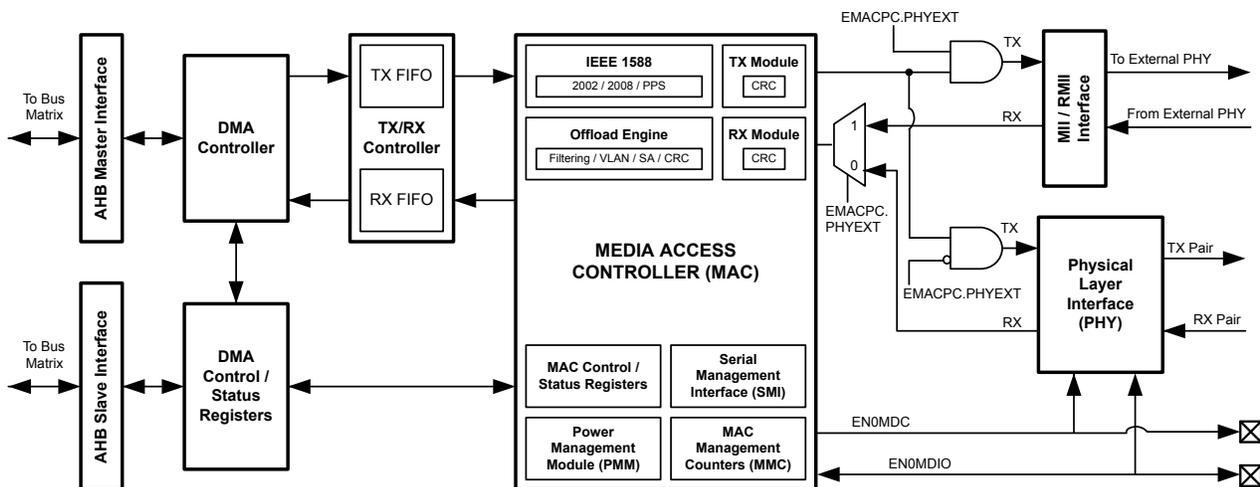

- Conforms to the IEEE 802.3 specification
 - 10BASE-T/100BASE-TX IEEE-802.3 compliant
 - Supports 10/100 Mbps data transmission rates
 - Supports full-duplex and half-duplex (CSMA/CD) operation
 - Supports flow control and back pressure
 - Full-featured and enhanced auto-negotiation
 - Supports IEEE 802.1Q VLAN tag detection
- Conforms to IEEE 1588-2002 Timestamp Precision Time Protocol (PTP) protocol and the IEEE 1588-2008 Advanced Timestamp specification
 - Transmit and Receive frame time stamping
 - Precision Time Protocol
 - Flexible pulse per second output
 - Supports coarse and fine correction methods
- Multiple addressing modes
 - Four MAC address filters
 - Programmable 64-bit Hash Filter for multicast address filtering
 - Promiscuous mode support
- Processor offloading
 - Programmable insertion (TX) or deletion (RX) of preamble and start-of-frame data
 - Programmable generation (TX) or deletion (RX) of CRC and pad data
 - IP header and hardware checksum checking (IPv4, IPv6, TCP/UDP/ICMP)
- Highly configurable
 - LED activity selection
 - Supports network statistics with RMON/MIB counters
 - Supports Magic Packet and wakeup frames
- Efficient transfers using integrated Direct Memory Access (DMA)
 - Dual-buffer (ring) or linked-list (chained) descriptors

- Round-robin or fixed priority arbitration between TX/RX
- Descriptors support up to 8 kB transfer blocks size
- Programmable interrupts for flexible system implementation
- Physical media manipulation
 - MDI/MDI-X cross-over support
 - Register-programmable transmit amplitude
 - Automatic polarity correction and 10BASE-T signal reception
- MII and RMIi interface support

24.1 Block Diagram

Figure 24-1 on page 1589 shows the block diagram of the Ethernet MAC with an integrated PHY interface:

Figure 24-1. Ethernet MAC with Integrated PHY Interface

24.2 Signal Description

The following table lists the external signals of the Ethernet Controller and describes the function of each. Some of the Ethernet signals have dedicated functions while the others listed in the table are alternate functions for GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for these Ethernet module signals. The `AFSEL` bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 803) should be set to assign the Ethernet signals. The number in parentheses is the encoding that must be programmed into the `PMCn` field in the **GPIO Port Control (GPIOCTL)** register (page 820) to assign the Ethernet signal to the specified GPIO port pin. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 772. The remaining signals (with the word "fixed" in the Pin Mux/Pin Assignment column) have a fixed pin assignment and function.

Table 24-1. Ethernet Signals (212BGA)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description |
|-------------|-----------------|-------------------------------|----------|-------------|---|
| EN0COL | N18 | PM7 (14) | I | TTL | Ethernet 0 Collision Detect. |
| EN0CRS | N19 | PM6 (14) | I | TTL | Ethernet 0 Carrier Sense. |
| EN0INTRN | U19 D6 | PK4 (7) PP0 (7) | I | TTL | Ethernet 0 Interrupt from the Ethernet PHY. |
| EN0LED0 | U6 U19 | PF0 (5) PK4 (5) | O | TTL | Ethernet 0 LED 0. |
| EN0LED1 | V7 V16 | PF4 (5) PK6 (5) | O | TTL | Ethernet 0 LED 1. |
| EN0LED2 | V6 V17 | PF1 (5) PK5 (5) | O | TTL | Ethernet 0 LED 2. |
| EN0MDC | A17 W6 | PB2 (5) PF2 (5) | O | TTL | Ethernet 0 Management Data Clock. |
| EN0MDIO | B17 T7 | PB3 (5) PF3 (5) | I/O | TTL | Ethernet 0 Management Data Input/Output signal. |
| EN0PPS | N15 T2 C8 | PG0 (5) PH5 (5) PJ0 (5) | O | TTL | Ethernet 0 Pulse-Per-Second (PPS) Output. |
| EN0RREF_CLK | M18 | PM4 (14) | I/O | TTL | Ethernet 0 Reference Clock. |
| EN0RXCK | V5 | PA6 (14) | I | TTL | Ethernet 0 Receive Clock. |
| EN0RXD0 | W12 W10 | PQ5 (14) PT0 (14) | I | TTL | Ethernet 0 Receive Data 0. |
| EN0RXD1 | U15 V10 | PQ6 (14) PT1 (14) | I | TTL | Ethernet 0 Receive Data 1. |
| EN0RXD2 | V17 | PK5 (14) | I | TTL | Ethernet 0 Receive Data 2. |
| EN0RXD3 | U19 | PK4 (14) | I | TTL | Ethernet 0 Receive Data 3. |
| EN0RXDV | U14 R13 | PG7 (14) PS7 (14) | I | TTL | Ethernet 0 Receive Data Valid. |
| EN0RXER | V12 U10 | PG6 (14) PS6 (14) | I | TTL | Ethernet 0 Receive Error. |
| EN0RXIN | V13 | fixed | I/O | TTL | Ethernet PHY negative receive differential input. |
| EN0RXIP | W13 | fixed | I/O | TTL | Ethernet PHY positive receive differential input. |
| EN0TXCK | V11 | PG2 (14) | I | TTL | Ethernet 0 Transmit Clock. |
| EN0TXD0 | K17 V9 | PG4 (14) PS4 (14) | O | TTL | Ethernet 0 Transmit Data 0. |
| EN0TXD1 | K15 T13 | PG5 (14) PS5 (14) | O | TTL | Ethernet 0 Transmit Data 1. |
| EN0TXD2 | V16 | PK6 (14) | O | TTL | Ethernet 0 Transmit Data 2. |
| EN0TXD3 | W16 | PK7 (14) | O | TTL | Ethernet 0 Transmit Data 3. |

| EN0TXER | T12 | PN6 (14) | O | TTL | Ethernet 0 transmit error. |
| EN0TXON | V14 | fixed | I/O | TTL | Ethernet PHY negative transmit differential output. |
| EN0TXOP | V15 | fixed | I/O | TTL | Ethernet PHY positive transmit differential output. |
| RBIAS | W15 | fixed | O | Analog | 4.87-kΩ resistor (1% precision) for Ethernet PHY. |

24.3 Functional Description

The Ethernet Controller is made up of the following sub-modules:

- Clock Control
- MII/RMII Interface Module
- DMA Controller
- Transmit/Receive Controller (TX/RX Controller)
- Media Access Controller (MAC)
- AHB Bus Interface
- PHY Interface

The following sections describe the features and functions of each sub-module.

24.3.1 Ethernet Clock Control

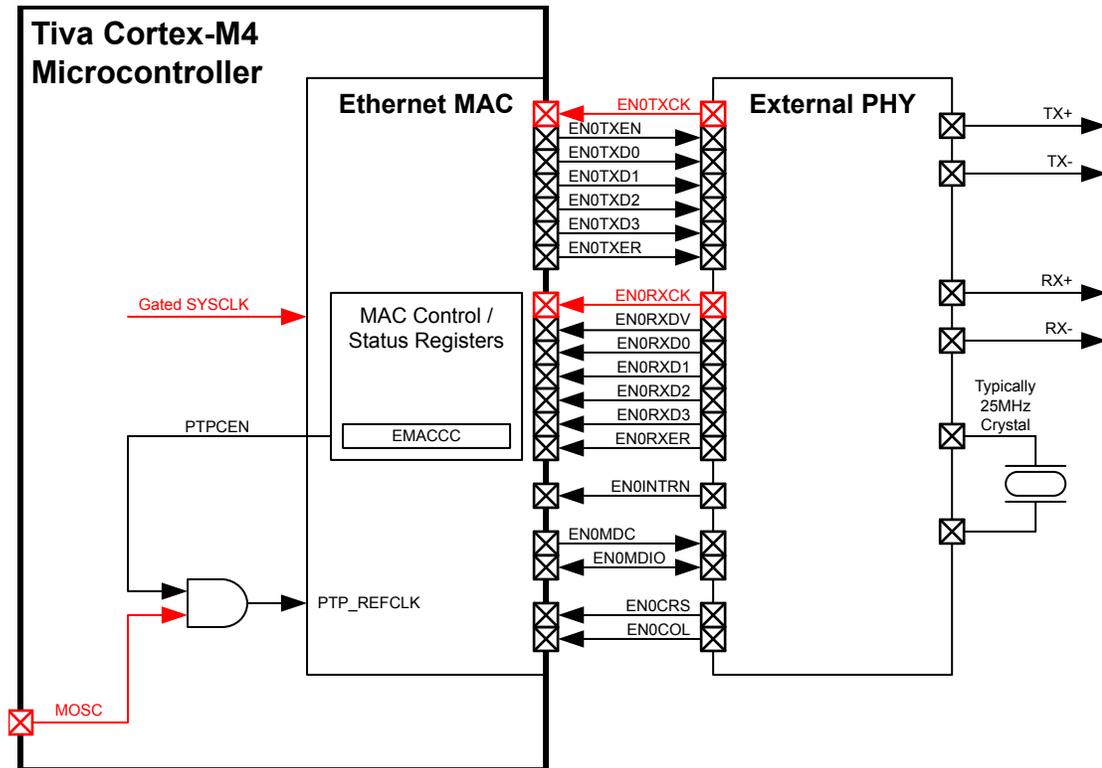

Available clock sources are dependent on the interface chosen. The following sections describe the clock control for the various interfaces.

24.3.1.1 PHY Interface

The Ethernet Controller Module and Integrated PHY receive two clock inputs:

- A gated system clock acts as the clock source to the Control and Status registers (CSR) of the Ethernet MAC. The SYSCLK frequency for Run, Sleep and Deep Sleep mode is programmed in the System Control module. Refer to “System Control” on page 231 for more information on programming SYSCLK and enabling the Ethernet MAC.
- The PHY receives the main oscillator (MOSC) which must be 25 MHz \pm 50 ppm for proper operation. The MOSC source can be a single-ended source or a crystal. Figure 24-2 on page 1592 shows the clock inputs to the Ethernet Controller Module.

Figure 24-3. MII Clock Structure

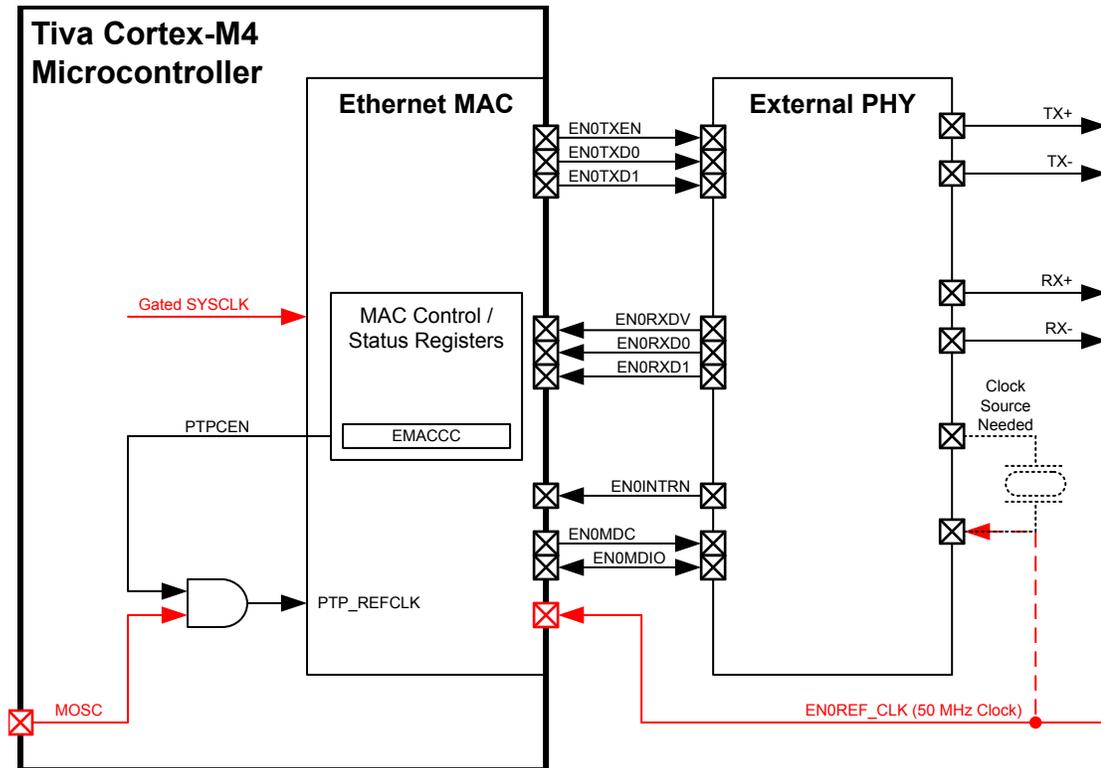

24.3.1.3 RMII Interface

There are three clock sources that interface to the Ethernet MAC in an RMII configuration:

- Gated system clock (SYSCLK): The SYSCLK signal acts as the clock source to the Control and Status registers (CSR) of the Ethernet MAC. The SYSCLK frequency for Run, Sleep and Deep Sleep mode is programmed in the System Control module. Refer to “System Control” on page 231 for more information on programming SYSCLK and enabling the Ethernet MAC.
- MOSC: A gated version of the MOSC clock is provided as the Precision Time Protocol (PTP) reference clock (PTPREF_CLK). The MOSC clock source can be a single-ended source on the OSC0 pin or a crystal on the OSC0 and OSC1 pins. When advanced timestamping is used and the PTP module has been enabled by setting the PTPCEN bit in the **EMACCC** register, the MOSC drives PTPREF_CLK. PTPREF_CLK has a minimum frequency requirement of 5 MHz and a maximum frequency of 25 MHz. Refer to “IEEE 1588 and Advanced Timestamp Function” on page 1625 for more information.
- ENOREF_CLK: When using RMII, a 50 MHz external reference clock must drive the ENOREF_CLK input signal and the external PHY. Depending on the configuration of the FES bit in the **Ethernet MAC Configuration (EMACCFG)** register, the reference clock input (ENOREF_CLK) is divided by 20 for 10 Mbps or 2 for 100 Mbps operation and used as the clock for receive and transmit data.

Figure 24-4 on page 1594 depicts the clock inputs to the RMII clock interface.

Figure 24-4. RMI Clock Structure

24.3.2 MII/RMII Interface Signals

The MAC Module has the capability of providing an MII or RMII interface depending on the interface selected in the **Ethernet MAC Peripheral Configuration (EMACPC)** register, at offset 0xFC4. Except for EN0REF_CLK, the signals used for RMII mode are a subset of the MII interface signals. Thus, Table 24-2 on page 1594 details the MII signals that are used in RMII mode and the RMII function to which they correspond. In addition, the GPIO pin they are muxed with is listed.

Table 24-2. MII and RMII Interface Signals

| MII Signal | RMII | RMII Standard Name and Function | GPIO |
|------------|------------|--|---------|
| N/A | EN0REF_CLK | REF_CLK: Synchronous clock reference for receive, transmit and control | PM4 |
| EN0TXCK | Not Used | N/A | PG2 |
| EN0TD3 | Not Used | N/A | PK7 |
| EN0TXD2 | Not Used | N/A | PK6 |
| EN0TXD1 | EN0TXD1 | TXD1: Transmit Data 1 | PG5/PS5 |
| EN0TXD0 | EN0TXD0 | TXD0: Transmit Data 0 | PG4/PS4 |
| EN0TXEN | EN0TXEN | TEX_EN: Transmit Enable | PG3/PR7 |
| EN0TXER | Not Used | N/A | PN6 |
| EN0RXCK | Not Used | N/A | PA6 |
| EN0RXD3 | Not Used | N/A | PK4 |
| EN0RXD2 | Not Used | N/A | PK5 |
| EN0RXD1 | EN0RXD1 | RXD1: Receive Data 1 | PQ6/PT1 |

Table 24-2. MII and RMI Interface Signals (continued)

| MII Signal | RMI | RMI Standard Name and Function | GPIO |
|------------|----------|--|-------------|
| EN0RXD0 | EN0RXD0 | RXD0: Receive Data 0 | PQ5/PT0 |
| EN0RXDV | EN0RXDV | CRS_DV: Carrier Sense/Receive Data Valid | PG7/PS7 |
| EN0RXER | Not Used | RX_ER: Receive Error ^a | PG6/PS6 |
| EN0COL | Not Used | N/A | PM7 |
| EN0CRS | Not Used | N/A | PM6 |
| EN0MDC | EN0MDC | MDC: Management Data Clock | PB2/PF2 |
| EN0MDIO | EN0MDIO | MDIO: Management Data Input/Output | PB3/PF3 |
| EN0PPS | EN0PPS | Pulse-Per-Second (PPS) Output (optional-this is not a standard RMI signal) | PG0/PJ0/PH5 |
| EN0INTRN | EN0INTRN | Interrupt to Ethernet PHY (optional-this is not a standard RMI signal) | PK4/PP0 |

a. RX_ER is an optional standard RMI signal and is not used in this device

24.3.3 DMA Controller

The Ethernet Controller's integrated DMA is used to optimize data transfer between the MAC and system SRAM memory. The DMA has independent transmit and receive engines.

The DMA transmit engine transfers data from system memory to the Ethernet TX/RX Controller, while the receive engine transfers data from the RX FIFO to the system memory. The controller uses descriptors to efficiently move data from source to destination with minimal CPU intervention. The DMA is designed for packet-oriented data transfers such as frames in Ethernet. Fixed burst lengths of 1, 4, 8, or 16 words are supported along with re-initiation of bursts when retry or burst termination responses occur. For a burst retry, if the remaining address count is greater than 1 and the `RIB` bit in the **Ethernet MAC DMA Bus Mode (EMACDMABUSMOD)** register is clear, then the transfer resends data in one continuous burst. When one transfer is left, it is done as a single burst and the transaction is terminated immediately afterward. If the `RIB` bit in the **EMACDMABUSMOD** register is set, the DMA sends the remaining data in fixed burst sizes of 1, 4, 8, or 16 words.

The application may also choose between solely fixed bursts or mixed bursts by the DMA. If the `MB` bit is set and the `FB` bit is clear in the **EMACDMABUSMOD** register, then the DMA uses fixed bursts for burst sizes less than 16 and a full, non-divided burst for lengths greater than 16. Fixed burst lengths allow for more DMA bus arbitration with other masters. Maximum burst transfer lengths can be programmed for both the receive and transmit channels of the DMA through the `PBL`, `RPBL` and `8xPBL` bit fields in the **EMACDMABUSMOD** register.

The DMA Controller requests a read transfer only when it can accept the received burst data completely. Data read from the bus is always pushed into the DMA without any delay or busy cycles. The DMA requests write transfers only when it has sufficient data to transfer the burst completely. When operating in fixed burst length mode, the DMA interface continues to burst with dummy data until the specified length is completed. The Ethernet controller can be programmed to interrupt the CPU in situations such as Frame Transmit and Receive transfer completion, and other normal/error conditions.

The integrated Ethernet DMA communicates through two data structures:

- Control and Status registers
- Descriptor lists and data buffers.

The DMA writes data frames received by the MAC to the receive buffer in system memory and transfers data frames for transmission from system memory to the MAC. Descriptors that reside in the system memory act as pointers to these buffers.

There are two descriptor lists: one for reception and one for transmission. The base address of each list is written into the **Ethernet MAC Receive Descriptor List Address (EMACRXDLADDR)** register at offset 0xC0C and the **Ethernet Mac Transmit Descriptor List Address (EMACTXDLADDR)** register at offset 0xC10, respectively.

The descriptor structure can contain up to 8 words (32 bytes). These are described in more detail in “Enhanced and Alternate Descriptors” on page 1598. A descriptor list is forward linked (either implicitly or explicitly). The last descriptor may point back to the first entry to create a ring structure. Explicit chaining of descriptors is accomplished by enabling second address chaining in both the Receive and Transmit descriptors (RDES0[14] and TDES0[20]). The descriptor lists reside in the SRAM memory address space. Each descriptor can point to a maximum of two buffers. This enables two buffers to be used at different physical addresses rather than contiguous buffers in memory.

The data buffer also resides in the physical memory space and consists of an entire frame or part of a frame, but cannot exceed a single frame. Buffers contain only data and buffer status is maintained in the descriptor. Data chaining refers to frames that span multiple data buffers. However, a single descriptor cannot span multiple frames. The DMA skips to the next frame buffer when the end-of-frame is detected. Data chaining can be enabled or disabled through the descriptors.

Note: The EMAC DMA Controller only has access to internal system SRAM memory.

24.3.3.1 Burst Access

The DMA attempts to execute fixed length Burst transfers if the **FB** bit is set in the **EMACDMABUSMOD** register. The maximum burst length is indicated and limited by the **PBL** field in the **EMACDMABUSMOD** register. The Receive and Transmit descriptors are always accessed in the maximum possible (limited by **PBL**) burst-size for the bytes to be read.

The TX DMA initiates a transfer only when there is sufficient space in the FIFO to accommodate the configured burst or remaining bytes of the end of a frame. When the DMA is configured for fixed-length burst, it transfers data using the best combination of fixed burst sizes of 4, 8, or 16 and single transactions. Otherwise when the **FB** bit is clear in the **EMACDMABUSMOD** register, the DMA transfers data as a continuous undefined burst and single transactions.

The RX DMA initiates a data transfer only when sufficient data to accommodate the configured burst is available in RX FIFO or when the end-of-frame (when it is less than the configured burst length) is detected in the RX FIFO. The DMA indicates the start address and the number of transfers required to the system. When the **FB** bit is set in the **EMACDMABUSMOD** register, then it transfers data using the best combination of fixed burst sizes of 4, 8, or 16 and single transactions. If the end-of-frame is reached before the fixed-burst ends, then dummy transfers are performed in order to complete the fixed-burst. Otherwise, if the **FB** bit is clear, the DMA transfers data using **INCR** (undefined length) and **SINGLE** transactions. When the DMA is configured for address-aligned transfers, both DMA engines ensure that the first burst transfer on the system bus is less than or equal to the size of the configured **PBL** in the **EMACDMABUSMOD** register. Thus, all subsequent transfers start at an address that is aligned to the configured **PBL**. The DMA can only align the address for burst transfers up to size 16 because only bursts of 16 are supported.

24.3.3.2 Data Buffer Alignment

The transmit and receive data buffers do not have any restrictions on the start address alignment. For example, in systems with 32-bit memory, the start address for the buffers can be aligned to any of the four bytes. However, the DMA always initiates write transfers, with address aligned to the bus

width and dummy data (old data) in the byte lanes that are not valid. This typically happens during the transfer of the beginning or end of an Ethernet frame. The software driver should discard the dummy bytes based on the start address of the buffer and size of the frame.

For example, if the transmit buffer address is 0x0000.0FF2, and 15 bytes need to be transferred, then the DMA reads five full words from address 0x0000.0FF0, but when transferring data to the TX FIFO, the extra bytes (the first two bytes) are dropped or ignored. Similarly, the last 3 bytes of the last transfer are also ignored. The DMA always ensures that it transfers a full 32-bit data to the TX FIFO, unless it is the end of frame.

If the receive buffer address is 0x0000.0FF2 and 15 bytes of a received frame need to be transferred, then the DMA writes five full words from address 0x0000.0FF0. However, the first two bytes of first transfer and the last three bytes of the fifth transfer have dummy data. The DMA considers the offset address only if it is the first Receive buffer of the frame. The DMA ignores the offset address and performs full word writes for the middle and the last Receive buffer of the frame.

24.3.3.3 Buffer Size Calculations

The DMA does not update the size fields in the Transmit and Receive descriptors. The DMA updates only the status fields (RDES and TDES) of the descriptors. The driver has to perform the size calculations. The TX DMA transfers the exact number of bytes (indicated by buffer size fields of TDES1) to the MAC. If a descriptor is marked as first (FS bit of TDES0 is set), then the DMA marks the first transfer from the buffer as the start-of-frame (SOF). If a descriptor is marked as last (LS bit of TDES0), then the DMA marks the last transfer from that data buffer as the end-of frame (EOF).

The RX DMA transfers data to a buffer until the buffer is full or the end-of frame is received from the RX/TX Controller. If a descriptor is not marked as last (LS bit of RDES0), then the descriptor's corresponding buffer(s) are full and the amount of valid data in a buffer is accurately indicated by its buffer size field minus the data buffer pointer offset when the FS bit of that descriptor is set. The offset is zero when the data buffer pointer is aligned to the data bus width. If a descriptor is marked as last, then the buffer may not be full (as indicated by the buffer size in RDES1). To compute the amount of valid data in this final buffer, the driver must read the frame length (FL bits of RDES0) and subtract the sum of the buffer sizes of the preceding buffers in this frame. The Receive DMA always transfers the start of next frame with a new descriptor.

Note: Even when the start address of a receive buffer is not aligned to the data width of 32-bit system bus, the system should allocate a receive buffer of a size aligned to the system bus width. For example, if the system allocates a 1,024-byte (1 KB) receive buffer starting from address 0x1000, the software can program the buffer start address in the Receive descriptor to have a 0x1002 offset. The Receive DMA writes the frame to this buffer with dummy data in the first two locations (0x1000 and 0x1001). The actual frame is written from location 0x1002. Thus, the actual useful space in this buffer is 1,022 bytes, even though the buffer size is programmed as 1,024 bytes, because of the start address offset.

24.3.3.4 DMA Arbiter

The arbiter inside the DMA module performs the arbitration between the Transmit and Receive channel accesses. The DMA can be configured to arbitrate in a round-robin or fixed-priority configuration. When the **DA** bit of the **EMACDMABUSMOD** register is clear, the DMA arbiter allocates the data bus in the ratio set by the **PR** bit field of the **EMACDMABUSMOD** register when both the TX and RX DMA request access at the same time. When the **DA** bit is set, the RX DMA always has priority over the TX DMA for data access by default. However if the **TXPR** bit of the **EMACDMABUSMOD** register is also set, then the TX DMA always gets priority over the RX DMA.

24.3.3.5 Enhanced and Alternate Descriptors

Enhanced Descriptors can contain up to eight words (32 bytes) and buffers of up to 8 KB (useful for Jumbo frames). Enhanced Descriptors support IEEE 1588-2008 Advanced Timestamp and IPC Full Checksum (Type 2) Offload. These enhanced features are enabled with the `TSEN` bit of the **EMACTIMSTCTRL** register and the `IPC` bit of the **EMACCFG** register, respectively.

When using Enhanced Descriptors, set the descriptor size to eight words with the Alternate Descriptor Size (`ATDS`) bit in the **Ethernet MAC DMA Bus Mode (EMACDMABUSMOD)** register. If these enhanced features are not enabled, the extended descriptors (DES4 to DES7) are not required. Therefore, the software can use Alternate Descriptors with a default size of 16 bytes (4 words). For alternate descriptors, the software should clear the Alternate Descriptor Size (`ATDS`) bit in the **Ethernet MAC DMA Bus Mode (EMACDMABUSMOD)** register.

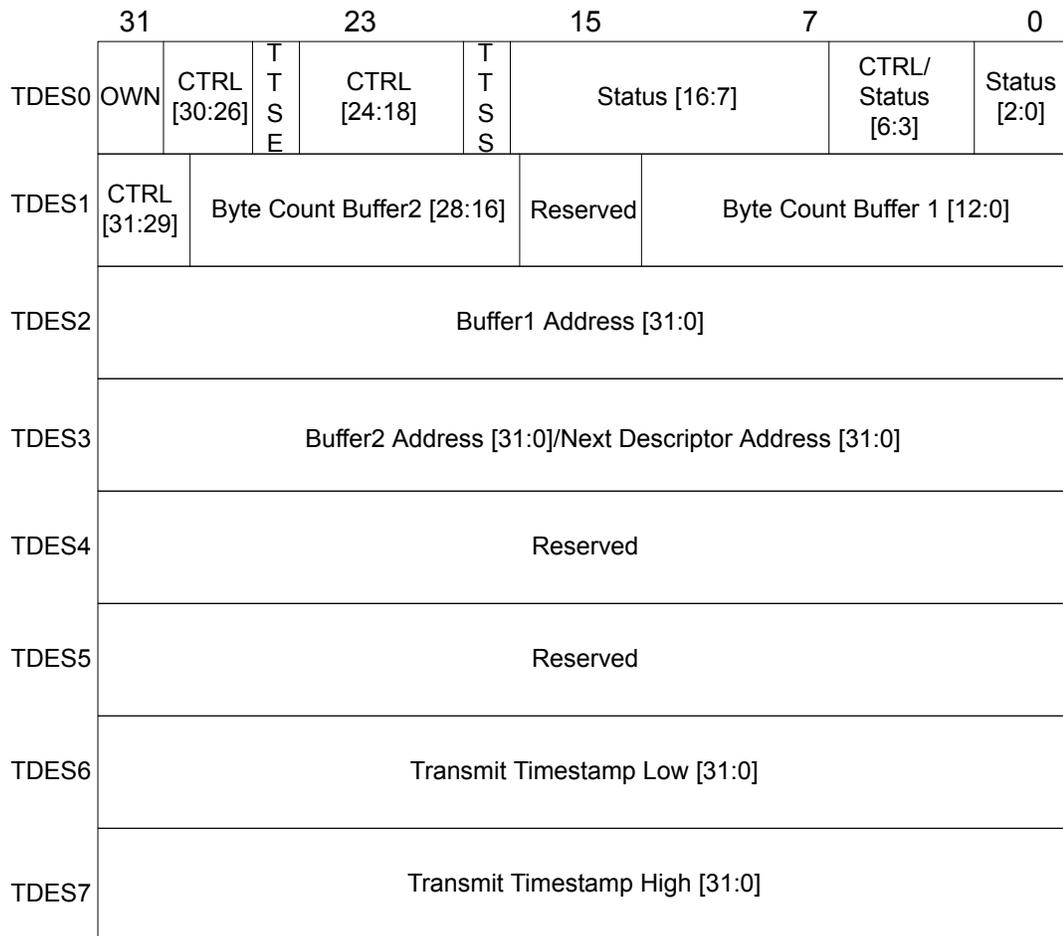

See the section called “Enhanced Transmit Descriptor” on page 1598 and the section called “Enhanced Receive Descriptor” on page 1603 for more details on the descriptor structure.

Enhanced Transmit Descriptor

The MAC requires at least one descriptor for a transmit frame. In addition to two buffers, two byte-count buffers, and two address pointers, the transmit descriptor has control fields which can be used to control the MAC operation on per-transmit frame basis. Figure 24-5 on page 1599 shows the enhanced transmit descriptor. Software must program the control bits `TDES0[31:18]` during descriptor initialization. When the DMA updates the descriptor, it writes back all the control bits to their initialized value, clears the `OWN` bit and updates the status bits.

With advanced timestamp support, the snapshot of the timestamp to be taken can be enabled for a given frame by setting Bit 25 (`TTSE`) of `TDES0`. When the descriptor is closed (that is, when the `OWN` bit is cleared), the timestamp is written into `TDES6` and `TDES7`.

Note: When the Advanced Timestamp feature is enabled, software should set the `ATDS` bit of the **Ethernet MAC DMA Bus Mode (EMACDMABUSMOD)** register, offset `0xC00`, so that the DMA operates with extended descriptor size. When this control bit is reset to the default (0), the `TDES4-TDES7` descriptor space is not valid and only Alternate Descriptors are available, with a default size of 16 bytes (4 words).

Figure 24-5. Enhanced Transmit Descriptor Structure

The following tables define the Enhanced Transmit Descriptors. Transmit Descriptor 0 (TDES0) contains the transmitted frame status and the descriptor ownership information. TDES1 contains the buffer sizes and other bits which control the descriptor chain or ring and the frame being transferred. TDES2 contains the address pointer to the first buffer of the descriptor. TDES3 contains the address pointer either to the second buffer of the descriptor or the next descriptor. TDES6 and TDES7 contain the timestamp.

Table 24-3. Enhanced Transmit Descriptor 0 (TDES0)

| Bit | Description |
|-----|---|
| 31 | OWN: Own Bit When set, this bit indicates that the descriptor is owned by the DMA. When this bit is reset, it indicates that the descriptor is owned by the Host. The DMA clears this bit either when it completes the frame transmission or when the buffers allocated in the descriptor are empty. The ownership bit of the First Descriptor of the frame should be set after all subsequent descriptors belonging to the same frame have been set. This avoids a possible race condition between fetching a descriptor and the driver setting an ownership bit. |
| 30 | IC: Interrupt on Completion When set this bit sets the Transmit Interrupt (TI) bit in the EMACDMARIS register when the frame contained in this descriptor has been transmitted. |

Table 24-3. Enhanced Transmit Descriptor 0 (TDES0) (continued)

| Bit | Description |
|-------|---|
| 29 | <p>LS: Last Segment</p> <p>When set, this bit indicates that the buffer contains the last segment of the frame. When this bit is set, the TBS1 or TBS2 field in TDES1 should have a non-zero value.</p> |
| 28 | <p>FS: First Segment</p> <p>When set, this bit indicates that the buffer contains the first segment of a frame.</p> |
| 27 | <p>DC: Disable CRC</p> <p>When set, the MAC does not append a Cyclic Redundancy Check (CRC) to the end of the transmitted frame. This is valid only when the first segment (TDES0[28]) is set.</p> |
| 26 | <p>DP: Disable Padding</p> <p>When set, the MAC does not automatically add padding to a frame shorter than 64 bytes. When this bit is reset, the DMA automatically adds padding and CRC to a frame shorter than 64 bytes, and the CRC field is added despite the state of the DC (TDES0[27]) bit. This is valid only when the first segment (TDES0[28]) is set.</p> |
| 25 | <p>TTSE: Transmit Timestamp Enable</p> <p>When set, this bit enables IEEE1588 hardware timestamping for the transmit frame referenced by the descriptor. This bit is only valid when the First Segment Control bit (TDES0[28]) is set.</p> |
| 24 | <p>CRCR: CRC Replacement Control</p> <p>When set, the MAC replaces the last four bytes of the transmitted packet with recalculated CRC bytes. The CPU should ensure that the CRC bytes are present in the frame being transferred from the Transmit Buffer. CRC replacement is done only when Bit 27 (DC) is set to 1.</p> |
| 23:22 | <p>CIC: Checksum Insertion Control</p> <p>These bits control the insertion of checksums in Ethernet frames that encapsulate TCP, UDP, or ICMP over IPv4 or IPv6. This field is valid when the First Segment control bit (TDES0[28]) is set.</p> <ul style="list-style-type: none"> ■ 0x0 = Do nothing. Checksum Engine bypassed. ■ 0x1 = Insert IPv4 header checksum. Use this value to insert IPv4 header checksum when the frame encapsulates an IPv4 datagram. ■ 0x2 = Insert TCP/UDP/ICMP checksum. The checksum is calculated over the TCP, UDP, or ICMP segment only and the TCP, UDP, or ICMP pseudo-header checksum is assumed to be present in the corresponding input frame's Checksum field. An IPv4 header checksum is also inserted if the encapsulated datagram conforms to IPv4. ■ 0x3 = Insert a TCP/UDP/ICMP checksum that is fully calculated in this engine. The TCP, UDP, or ICMP pseudo-header is included in the checksum calculation, and the input frame's corresponding Checksum field has an all-zero value. An IPv4 Header checksum is also inserted if the encapsulated datagram conforms to IPv4. <p>The Checksum engine detects whether the TCP, UDP, or ICMP segment is encapsulated in IPv4 or IPv6 and processes its data accordingly.</p> |
| 21 | <p>TER: Transmit End of Ring</p> <p>When set, this bit indicates that the descriptor list reached its final descriptor. The DMA returns to the base address of the list, creating a descriptor ring.</p> |
| 20 | <p>TCH: Second Address Chained</p> <p>When set, this bit indicates that the second address in the descriptor is the Next Descriptor address rather than the second buffer address. When TDES0[20] is set, TBS2 (TDES1[28:16]) is a "don't care" value. TDES0[21] takes precedence over TDES0[20].</p> |

Table 24-3. Enhanced Transmit Descriptor 0 (TDES0) (continued)

| Bit | Description |
|-------|---|
| 19:18 | <p>VLIC: VLAN Insertion Control</p> <p>When set, these bits request the MAC to perform VLAN tagging or untagging before transmitting the frames. If the frame is modified for VLAN tags, the MAC automatically recalculates and replaces the CRC bytes.</p> <p>The values of this field are as follows:</p> <ul style="list-style-type: none"> ■ 0x0= Do not add a VLAN tag ■ 0x1= Remove the VLAN tag from the frames before transmission. ■ 0x2= Insert a VLAN tag with the tag value programmed in the Ethernet MAC VLAN Tag Inclusion or Replacement (EMACVLNINCREP) register, offset 0x584. ■ 0x3= Replace the VLAN tag in frame with the tag value programmed in the EMACVLNINCREP register. This field is valid when the First Segment control bit (TDES0[28]) is set. |
| 17 | <p>TTSS:TX Timestamp</p> <p>This status bit indicates that a timestamp has been captured for the corresponding transmit frame. When this bit is set, TDES6 and TDES7 have timestamp values that were captured for the transmit frame. This field is valid only when the Last Segment control bit (TDES0[29]) in a descriptor is set.</p> |
| 16 | <p>IHE: IP Header Error</p> <p>When set, this bit indicates that the Checksum Offload engine detected an IP header error. This bit is valid only when TX Checksum Offload is enabled. Otherwise, it is reserved. If the Checksum Offload Engine detects an IP header error, it still inserts an IPv4 header checksum if the Ethernet Type field indicates an IPv4 payload.</p> |
| 15 | <p>ES: Error Summary</p> <p>Indicates the logical OR of the following bits:</p> <ul style="list-style-type: none"> ■ TDES0[16]: IP Header Error ■ TDES0[14]: Jabber Timeout ■ TDES0[13]: Frame Flush ■ TDES0[12]: Payload Checksum Error ■ TDES0[11]: Loss of Carrier ■ TDES0[10]: No Carrier ■ TDES0[9]: Late Collision ■ TDES0[8]: Excessive Collision ■ TDES0[2]: Excessive Deferral ■ TDES0[1]: Underflow error |
| 14 | <p>JT: Jabber Timeout</p> <p>When set, this bit indicates that the MAC transmitter has experienced a jabber timeout. This bit can only be set when the Jabber Disabled (JD) bit of the EMACCFG register is clear.</p> |
| 13 | <p>FF: Frame Flushed</p> <p>When set, this bit indicates that the DMA flushed the frame because of a software flush command given by the CPU.</p> |
| 12 | <p>IPE: IP Payload Error</p> <p>When set, this bit indicates that MAC transmitter detected an error in the TCP, UDP, or ICMP IP datagram payload. The transmitter checks the payload length received in the IPv4 or IPv6 header against the actual number of TCP, UDP, or ICMP packet bytes received from the application and issues an error status in case of a mismatch.</p> |

Table 24-3. Enhanced Transmit Descriptor 0 (TDES0) (continued)

| Bit | Description |
|-----|---|
| 11 | <p>LC: Loss of Carrier</p> <p>When set, this bit indicates that Loss of Carrier occurred during frame transmission. This is valid only for the frames transmitted without collision and when the MAC operates in half-duplex mode.</p> |
| 10 | <p>NC: No Carrier</p> <p>When set, this bit indicates that the carrier sense signal from the PHY was not asserted during transmission.</p> |
| 9 | <p>LC: Late Collision</p> <p>When set, this bit indicates that frame transmission was aborted due to a collision occurring after the collision window (64 byte times including Preamble in MII Mode). Not valid if Underflow Error (bit 1) is set.</p> |
| 8 | <p>Excessive Collision</p> <p>When set, this bit indicates that the transmission was aborted after 16 successive collisions while attempting to transmit the current frame. If the Disable Retry (DR) bit in EMACCFG register is set, this bit is set after the first collision and the transmission of the frame is aborted.</p> |
| 7 | <p>VF: VLAN Frame</p> <p>When set, this bit indicates that the transmitted frame was a VLAN-type frame.</p> |
| 6:3 | <p>CC: Collision Count</p> <p>This 4-bit counter value indicates the number of collisions occurring before the frame was transmitted. The count is not valid when the Excessive Collision bit (TDES0[8]) is set.</p> |
| 2 | <p>ED: Excessive Deferral</p> <p>When set, this bit indicates that the transmission has ended because of excessive deferral of over 24,288 bit times (155,680 bits times when Jumbo Frame is enabled). This bit is dependent on the Deferral Check (DC) bit being enabled in the EMACCFG register.</p> |
| 1 | <p>UF: Underflow Error</p> <p>When set, this bit indicates that the MAC aborted the frame because the data arrived late from system memory. Underflow Error indicates that the DMA encountered an empty Transmit Buffer while transmitting the frame. The transmission process enters the suspended state and sets both Transmit Underflow (UNF) and Transmit Interrupt (TI) bit in the EMACDMARIS register.</p> |
| 0 | <p>DB: Deferred Bit</p> <p>This bit indicates the deferral mechanism is active and that the transmit state machine sends a JAM pattern to defer reception when it senses a carrier before a normal transmission is scheduled. This bit is only valid in half-duplex mode.</p> |

Table 24-4. Enhanced Transmit Descriptor 1 (TDES1)

| Bit | Description |
|-------|---|
| 31:29 | <p>SAIC: SA Insertion Control</p> <p>These bits request the MAC to add or replace the Source Address field in the Ethernet frame with the value given in the MAC Address 0 register. If the Source Address field is modified in a frame, the MAC automatically recalculates and replaces the CRC bytes.</p> <p>The Bit 31 specifies the MAC Address Register (1 or 0) value that is used for Source Address insertion or replacement. The following list describes the values of Bits[30:29]:</p> <ul style="list-style-type: none"> ■ 0x0= Do not include the source address. ■ 0x1= Insert the source address. For reliable transmission, the application must provide frames without source addresses. ■ 0x2= Replace the source address. For reliable transmission, the application must provide frames with source addresses. ■ 0x3= Reserved <p>These bits are valid when the First Segment control bit (TDES0[28]) is set.</p> |

Table 24-4. Enhanced Transmit Descriptor 1 (TDES1) (continued)

| Bit | Description |
|-------|---|
| 28:16 | TBS2: Transmit Buffer 2 Size This field indicates the second data buffer size in bytes. This field is not valid if TDES0[20] is set. |
| 15:13 | Reserved |
| 12:0 | TBS1: Transmit Buffer 1 Size These bits indicate the first data buffer byte size, in bytes. If this field is 0, the DMA ignores this buffer and uses Buffer 2 or the next descriptor, depending on the value of TCH (TDES0[20]). |

Table 24-5. Enhanced Transmit Descriptor 2 (TDES2)

| Bit | Description |
|------|---|
| 31:0 | Buffer 1 Address Pointer These bits indicate the physical address of Buffer 1. There is no limitation on the buffer address alignment. Note that the buffers are stored in SRAM. |

Table 24-6. Enhanced Transmit Descriptor 3 (TDES3)

| Bit | Description |
|------|--|
| 31:0 | Buffer 2 Address Pointer (Next Descriptor Address) Indicates the physical address of Buffer 2 when a descriptor ring structure is used. If the Second Address Chained (TDES0[20]) bit is set, this address contains the pointer to the physical memory where the Next Descriptor is present. The buffer address pointer must be aligned to the bus width only when TDES0[20] is set. Note that the buffers are stored in SRAM. |

Table 24-7. Enhanced Transmit Descriptor 6 (TDES6)

| Bit | Description |
|------|---|
| 31:0 | TTSL: Transmit Frame Timestamp Low This field is updated by DMA with the least significant 32 bits of the timestamp captured for the corresponding transmit frame. This field has the timestamp only if the Last Segment bit (LS), TDES0[29], in the descriptor is set and Timestamp status (TTSS) bit, TDES0[17], is set. |

Table 24-8. Enhanced Transmit Descriptor 7 (TDES7)

| Bit | Description |
|------|--|
| 31:0 | TTSH: Transmit Frame Timestamp High This field is updated by DMA with the most significant 32 bits of the timestamp captured for the corresponding receive frame. This field has the timestamp only if the Last Segment bit (LS), TDES0[29], in the descriptor is set and Timestamp status (TTSS) bit, TDES0[17], is set. |

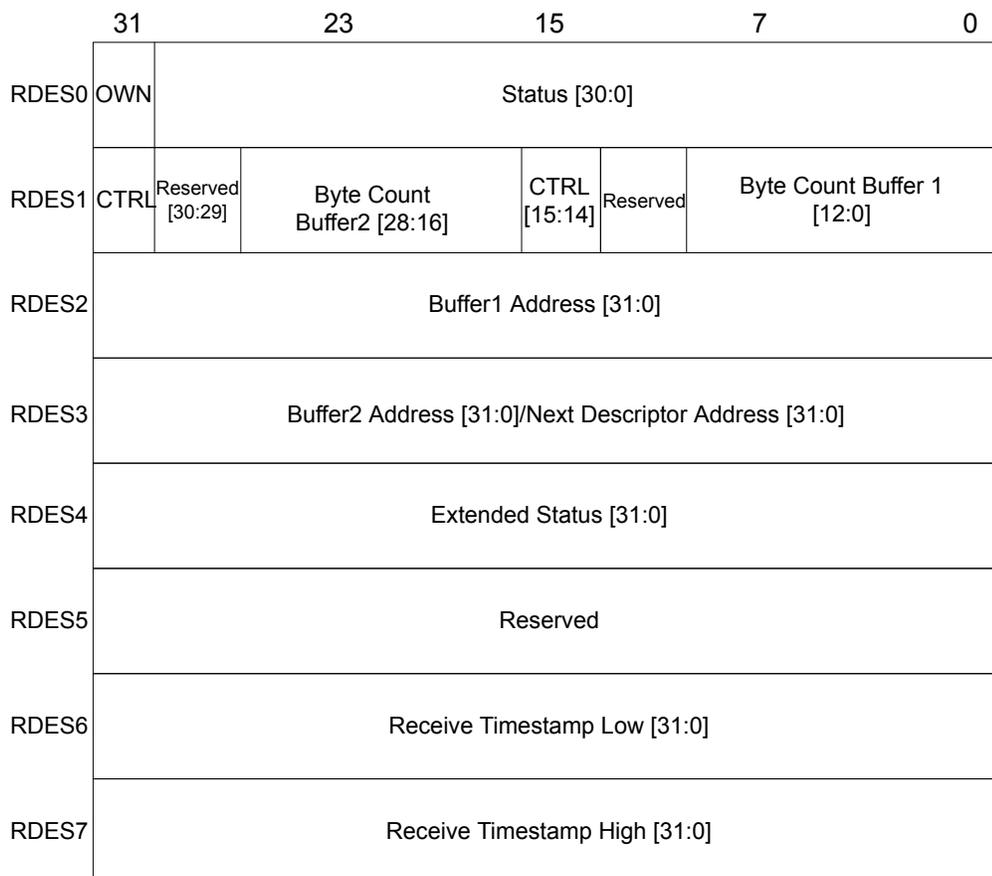

Enhanced Receive Descriptor

The DMA requires at least two descriptors when receiving a frame. The DMA always attempts to acquire an extra descriptor in anticipation of an incoming frame. Before the DMA closes a descriptor, it attempts to acquire the next descriptor even if no frames are received. In a single descriptor (receive) system, the subsystem generates a descriptor error if the receive buffer is unable to accommodate the incoming frame and the next descriptor is not owned by the DMA. Figure 24-6 on page 1604 shows the enhanced receive descriptor. This descriptor is used when Advanced Timestamp or the Checksum Offload Engine is enabled.

Note: When the Advanced Timestamp or Checksum Offload Engine features are enabled, software should set the ATDS bit of the **Ethernet MAC DMA Bus Mode (EMACDMABUSMOD)**

register, offset 0xC00, so that the DMA operates with extended descriptor size. When this control bit is reset to the default (0), the TDES4-TDES7 descriptor space is not valid and only Alternate Descriptors are available, with a default size of 16 bytes (4 words).

Figure 24-6. Enhanced Receive Descriptor Structure

The following tables define the Enhanced Receive Descriptors. RDES0 contains the received frame status, the frame length, and the descriptor ownership information. RDES1 contains the buffer sizes and other bits that control the descriptor chain or ring. RDES2 and RDES3 contains the address pointers to the first and second data buffers in the descriptor. The availability of the extended status is indicated by Bit 0 of RDES0. RDES6 and RDES7 are available only when the Advanced Timestamp or IP Checksum Full Offload feature is enabled.

Table 24-9. Enhanced Receive Descriptor 0 (RDES0)

| Bit | Description |
|-----|--|
| 31 | OWN: Own Bit When set, this bit indicates that the descriptor is owned by the DMA. When this bit is reset, it indicates that the descriptor is owned by the Host. The DMA clears this bit either when it completes the frame reception or when the buffers that are associated with this descriptor are full. |
| 30 | AFM: Destination Address Filter Fail When set, this bit indicates a frame failed in the DA filter in the MAC. |

Table 24-9. Enhanced Receive Descriptor 0 (RDES0) (continued)

| Bit | Description |
|-------|--|
| 29:16 | <p>FL: Frame Length</p> <p>These bits indicate the byte length of the received frame that was transferred to the system memory. This field is valid when the Last Descriptor (RDES0[8]) is set and either the Descriptor Error (RDES0[14]) or the Overflow Error bit (RDES0[11]) is clear.</p> <p>When the Last Descriptor bit is not set, this field indicates the accumulated number of bytes that have been transferred for the current frame. The inclusion of CRC length in the frame length depends on the settings of CRC configuration bits, <code>ACS</code> and <code>CST</code> in the EMACCFG register.</p> |
| 15 | <p>ES: Error Summary</p> <p>Indicates the logical OR of the following bits:</p> <ul style="list-style-type: none"> ■ RDES0[14]: Descriptor Error ■ RDES0[11]: Overflow Error ■ RDES0[7]: IPC Checksum (Type 2) or Giant Frame ■ RDES0[6]: Late Collision ■ RDES0[4]: Watchdog Timeout ■ RDES0[3]: Receive Error ■ RDES0[1]: CRC Error ■ RDES[4:3]: IP Header or Payload Error <p>This field is valid only when the Last Descriptor (RDES0[8]) is set.</p> |
| 14 | <p>DE: Descriptor Error</p> <p>When set, this bit indicates a frame truncation caused by a frame that does not fit within the current descriptor buffers, and that the DMA does not own the Next Descriptor. The frame is truncated. This field is valid only when the Last Descriptor (RDES0[8]) is set.</p> |
| 13 | <p>SAF: Source Address Filter Fail</p> <p>When set, this bit indicates that the SA field of frame failed the SA Filter in the MAC.</p> |
| 12 | <p>LE: Length Error</p> <p>When set, this bit indicates that the actual length of the frame received and the Length/Type field do not match. This bit is valid only when the Frame Type (RDES0[5]) bit is reset. Length error status is not valid when CRC error is present.</p> |
| 11 | <p>OE: Overflow Error</p> <p>When set, this bit indicates that the received frame is damaged because of buffer overflow in RX FIFO.</p> <p>Note: This bit is set only when the DMA transfers a partial frame to the application. This happens only when the RX FIFO is operating in the threshold mode. In the store-and-forward mode, all partial frames are dropped completely in RX FIFO.</p> |
| 10 | <p>VLAN: VLAN Tag</p> <p>When set, this bit indicates that the frame pointed to by this descriptor is a VLAN frame tagged by the MAC. The VLAN tagging depends on checking VLAN fields of the received frame configured in the Ethernet MAC VLAN Tag (EMACVLANTG) register, offset 0x01C</p> |
| 9 | <p>FS: First Descriptor</p> <p>When set, this bit indicates that this descriptor contains the first buffer of the frame. If the size of the first buffer is 0, the second buffer contains the beginning of the frame. If the size of the second buffer is also 0, the next Descriptor contains the beginning of the frame.</p> |
| 8 | <p>LS: Last Descriptor</p> <p>When set, this bit indicates that the buffers pointed to by this descriptor are the last buffers of the frame.</p> |

Table 24-9. Enhanced Receive Descriptor 0 (RDES0) (continued)

| Bit | Description |
|-----|--|
| 7 | Timestamp Available or Giant Frame When Advanced Timestamp feature is enabled, this bit indicates that a snapshot of the Timestamp is written in descriptor words 6 (RDES6) and 7 (RDES7). This is valid only when the Last Descriptor bit (RDES0[8]) is set. Otherwise, this bit, when set, indicates the Giant Frame Status. Giant frames are larger than 1,518-byte (or 1,522-byte for VLAN or 2,000-byte when Bit 27 of MAC Configuration register is set) normal frames and larger than 9,018-byte (9,022-byte for VLAN) frame when Jumbo Frame processing is enabled. |
| 6 | LC: Late Collision When set, this bit indicates that a late collision has occurred while receiving the frame in half-duplex mode. |
| 5 | FT: Frame Type When set, this bit indicates that the Receive Frame is an Ethernet-type frame (the LT field is greater than or equal to 1,536). When this bit is reset, it indicates that the received frame is an IEEE 802.3 frame. This bit is not valid for Runt frames less than 14 bytes. In addition when the IPC bit is set in the EMACCFG register, this bit conveys different information. See Table 24-10 on page 1606. |
| 4 | RWT: Receive Watchdog Timeout When set, this bit indicates that the Receive Watchdog Timer has expired while receiving the current frame and the current frame is truncated after the Watchdog Timeout. |
| 3 | RE: Receive Error When set, this bit indicates that an error occurred during frame reception. |
| 2 | DE: Dribble Bit Error When set, this bit indicates that the received frame has a non-integer multiple of bytes (odd nibbles). This bit is valid only in MII Mode. |
| 1 | CE: CRC Error When set, this bit indicates that a Cyclic Redundancy Check (CRC) Error occurred on the received frame. This field is valid only when the Last Descriptor bit (RDES0[8]) is set. |
| 0 | Extended Status Available/RX MAC Address When set, this bit indicates that the extended status is available in descriptor word 4 (RDES4). This is valid only when the Last Descriptor bit (RDES0[8]) is set. This bit is invalid when Bit 30 is set. |

Table 24-10 on page 1606 shows the frame information conveyed in bits 7, 5, and 0 of RDES0 when the Checksum Offload Engine is enabled and disabled through the `IPC` bit in the `EMACCFG` register.

Table 24-10. RDES0 Checksum Offload bits

| Bit 5: Frame Type | Bit 7: IPC Checksum Error | Bit 0: Payload Checksum Error | IPC bit value in EMACCFG register | Frame Status |
|-------------------|---------------------------|-------------------------------|-----------------------------------|---|
| 0 | 0 | 0 | X | IEEE 802.3 Type frame (Length field value is less than 1,536). This status definition is valid even when the Checksum Offload engine is disabled. |
| 1 | 0 | 0 | 0 | IPv4/IPv6 Type frame in which no checksum error is detected. |
| 1 | 0 | 0 | 1 | The frame is an IEEE 802.3 Type frame (Length field value is greater than or equal to 1,536). |
| 1 | 0 | 1 | 1 | IPv4/IPv6 Type frame with a payload checksum error detected |
| 1 | 1 | 1 | 1 | IPv4/IPv6 Type frame with both IP header and payload checksum errors detected |
| 0 | 0 | 1 | 1 | IPv4/IPv6 Type frame with no IP header checksum error and the payload check bypassed, due to an unsupported payload |
| 0 | 1 | 1 | 1 | A Type frame that is neither IPv4 or IPv6 (the Checksum Offload engine bypasses checksum completely.) |

Table 24-10. RDES0 Checksum Offload bits (continued)

| Bit 5: Frame Type | Bit 7: IPC Checksum Error | Bit 0: Payload Checksum Error | IPC bit value in EMACCFG register | Frame Status |
|-------------------|---------------------------|-------------------------------|-----------------------------------|--------------|
| 0 | 1 | 0 | X | Reserved |

Table 24-11. Enhanced Receive Descriptor 1 (RDES1)

| Bit | Description |
|-------|---|
| 31 | Disable Interrupt on Completion When set, this bit prevents the setting of the Receive Interrupt (R _I) bit in the EMACDMARIS register and prevents the receive interrupt from being asserted. |
| 30:29 | Reserved |
| 28:16 | RBS2: Receive Buffer 2 Size These bits indicate the second data buffer size. The buffer size must be a multiple of 4, even if the value of RDES3 (buffer 2 address pointer) is not aligned to the bus width. When the buffer size is not a multiple of 4, the resulting behavior is undefined. This field is not valid if RCH bit (RDES1[14]) is set. |
| 15 | RER: Receive End of Ring When set, this bit indicates that the descriptor list reached its final descriptor. The DMA returns to the base address of the list, creating a Descriptor Ring. |
| 14 | RCH: Second Address Chained When set, this bit indicates that the second address in the descriptor is the Next Descriptor address rather than the second buffer address. When this bit is set, RBS2 (RDES1[28:16]) is a "don't care" value. RDES1[15] takes precedence over RDES1[14]. |
| 13 | Reserved |
| 12:0 | RBS1: Receive Buffer 1 Size These bits indicate the first data buffer size in bytes. The buffer size must be a multiple of 4 even if the value of RDES2 (buffer 1 address pointer) is not aligned to the bus width. When the buffer size is not a multiple of 4, the resulting behavior is undefined. If this field is 0, the DMA ignores this buffer and uses Buffer 2 or the next descriptor depending on the value of RCH (Bit 14). |

Table 24-12. Enhanced Receive Descriptor 2 (RDES2)

| Bit | Description |
|------|---|
| 31:0 | Buffer 1 Address Pointer These bits indicate the physical address of Buffer 1. The DMA uses the configured value for its address generation when the RDES2 value is used to store the start of frame. The DMA performs a write operation with the RDES2[1:0] bits as 0 during the transfer of the start of frame but the frame data is shifted as per the actual Buffer address pointer. The DMA ignores RDES2[1:0] if the address pointer is to a buffer where the middle or last part of the frame is stored. Note that buffers should be word-aligned. |

Table 24-13. Enhanced Receive Descriptor 3 (RDES3)

| Bit | Description |
|------|--|
| 31:0 | Buffer 2 Address Pointer (Next Descriptor Address) These bits indicate the physical address of Buffer 2 when a descriptor ring structure is used. If the Second Address Chained (RDES1[14]) bit is set, this address contains the pointer to the physical memory where the Next Descriptor is present. If RDES1[14] is set, the buffer (Next Descriptor) address pointer must be bus word-aligned (RDES3[1:0] = 0) However, when RDES1[14] is reset, there are no limitations on the RDES3 value, except for the following condition: The DMA uses the configured value for its buffer address generation when the RDES3 value is used to store the start of frame. The DMA ignores RDES3 [1:0] if the address pointer is to a buffer where the middle or last part of the frame is stored. |

Table 24-14. Enhanced Received Descriptor 4 (RDES4)

| Bit | Description |
|-------|---|
| 31:15 | Reserved |
| 14 | Timestamp Dropped When set, this bit indicates that the timestamp was captured for this frame but got dropped in the RX FIFO because of overflow. |
| 13 | PTP Version When set, this bit indicates that the received PTP message uses the IEEE 1588 version 2 format. When reset, it uses the version 1 format. |
| 12 | PTP Frame Type When set, this bit indicates that the PTP message is sent directly over Ethernet. When this bit is clear and the message type is non-zero, it indicates that the PTP message is sent over UDP-IPv4 or UDP-IPv6. The information about IPv4 or IPv6 can be obtained from Bits 6 and 7. |
| 11:8 | MessageType These bits are encoded to give the type of the message received: <ul style="list-style-type: none"> ■ 0x0= No PTP message received ■ 0x1= SYNC (all clock types) ■ 0x2= Follow_Up (all clock types) ■ 0x3= Delay_Req (all clock types) ■ 0x4= Delay_Resp (all clock types) ■ 0x5= Pdelay_Req (in peer-to-peer transparent clock) ■ 0x6= Pdelay_Resp (in peer-to-peer transparent clock) ■ 0x7= Pdelay_Resp_Follow_Up (in peer-to-peer transparent clock) ■ 0x8= Announce ■ 0x9= Management ■ 0xA= Signaling ■ 0xB to 0xE= Reserved ■ 0xF= PTP packet with Reserved message type |
| 7 | IPv6 Packet Received When set, this bit indicates that the received packet is an IPv6 packet. This bit is updated only when the <code>IPC</code> bit of the EMACCFG register is set. |
| 6 | IPv4 Packet Received When set, this bit indicates that the received packet is an IPv4 packet. This bit is updated only when the <code>IPC</code> bit of the EMACCFG register is set. |
| 5 | IP Checksum Bypassed When set, this bit indicates that the checksum offload engine is bypassed. |
| 4 | IP Payload Error When set, this bit indicates that the 16-bit IP payload checksum (that is, the TCP, UDP, or ICMP checksum) that the core calculated does not match the corresponding checksum field in the received segment. It is also set when the TCP, UDP, or ICMP segment length does not match the payload length value in the IP Header field. This bit is valid when either Bit 7 or Bit 6 is set. |

Table 24-14. Enhanced Received Descriptor 4 (RDES4) (continued)

| Bit | Description |
|-----|--|
| 3 | <p>IP Header Error</p> <p>When set, this bit indicates that either the 16-bit IPv4 header checksum calculated by the core does not match the received checksum bytes, or the IP datagram version is not consistent with the Ethernet Type value. This bit is valid when either Bit 7 or Bit 6 is set.</p> |
| 2:0 | <p>IP Payload Type</p> <p>These bits indicate the type of payload encapsulated in the IP datagram processed by the Receive Checksum Offload Engine (COE). The COE sets this field to 0x0 if it does not process the IP datagram's payload due to an IP header error or fragmented IP packet.</p> <ul style="list-style-type: none"> ■ 0x0= Unknown or did not process IP payload ■ 0x1= UDP ■ 0x2= TCP ■ 0x3= ICMP ■ 0x4 to 0x7= Reserved <p>This bit is valid when either Bit 7 or Bit 6 is set.</p> |

Table 24-15. Enhanced Receive Descriptor 6 (RDES6)

| Bit | Description |
|------|--|
| 31:0 | <p>RTSL: Receive Frame Timestamp Low</p> <p>This field is updated by the DMA with the least significant 32 bits of the timestamp captured for the corresponding receive frame. This field is updated by the DMA only for the last descriptor of the receive frame which is indicated by Last Descriptor status bit (RDES0[8]).</p> |

Table 24-16. Enhanced Receive Descriptor 7 (RDES7)

| Bit | Description |
|------|--|
| 31:0 | <p>RTSH: Receive Frame Timestamp High</p> <p>This field is updated by DMA with the most significant 32 bits of the timestamp captured for the corresponding receive frame. This field is updated by DMA only for the last descriptor of the receive frame which is indicated by Last Descriptor status bit (RDES0[8]).</p> |

24.3.3.6 DMA Transmission Operation

The following sections describe the modes of the transmit operation.

TX DMA Default Operation

The TX DMA engine in default mode, operates as follows:

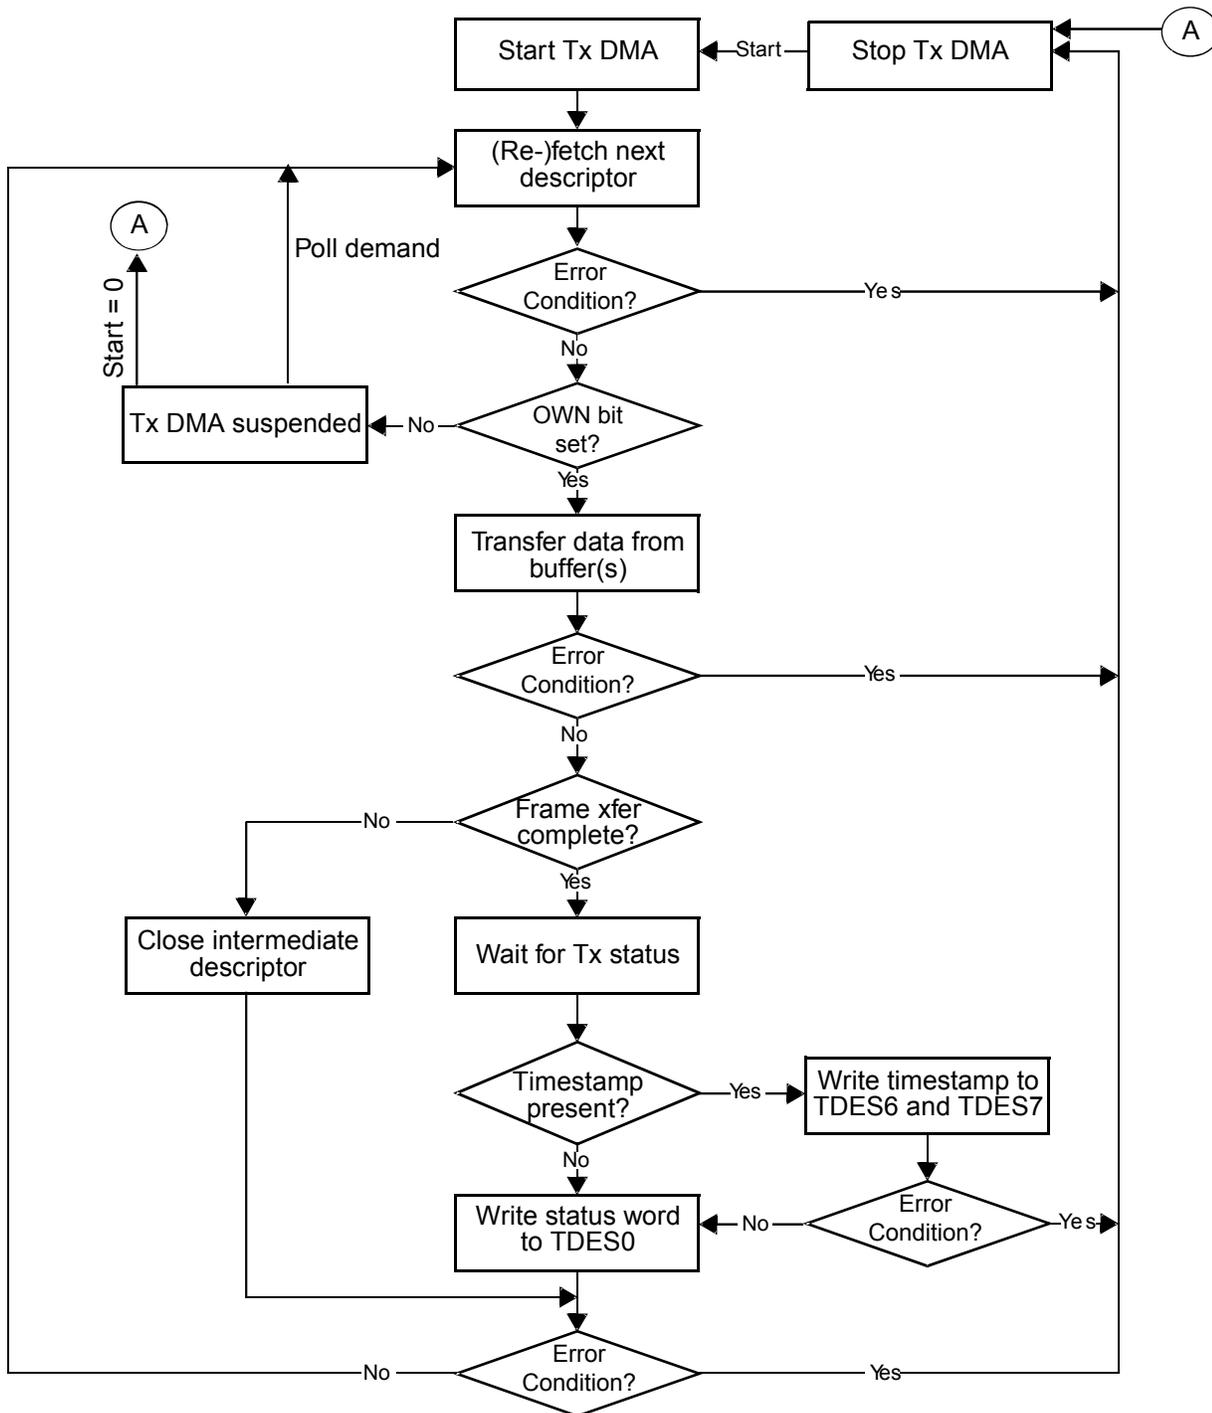

1. The CPU configures the transmit descriptor (TDES0-TDES3) and sets the OWN bit (TDES0[31]) after setting up the corresponding data buffers with the Ethernet frame.
2. When the ST bit of the **Ethernet MAC DMA Operation Mode (EMACDMAOPMODE)** register, offset 0xC18, is set, the DMA enters the RUN state.
3. While in RUN state, the DMA polls the Transmit Descriptor list for frames requiring transmission. After polling starts, it continues in either sequential descriptor ring order or chained order. If the DMA detects a descriptor flagged as owned by the CPU (TDES0[31]=0), or if an error condition occurs, transmission is suspended and both the Transmit Buffer Unavailable (TU) bit and the

Normal Interrupt Summary (NIS) bit are set in the **Ethernet MAC DMA Interrupt Status (EMACDMARIS)** register, offset 0xC14. The transmit engine then proceeds to Step 9.

4. If the acquired descriptor is flagged as owned by the DMA (TDES0[31]=1), the DMA decodes the transmit data buffer address from the acquired descriptor.
5. If the acquired descriptor is flagged as owned by DMA (TDES0[31] = 1), the DMA decodes the Transmit Data Buffer address from the acquired descriptor.
6. The DMA fetches the transmit data from system memory and transfers the data to the TX/RX Controller for transmission.
7. If the Ethernet frame is stored over data buffers in multiple descriptors, the DMA closes the intermediate descriptor and fetches the next descriptor. Steps 3, 4, and 5 are repeated until the end of the Ethernet frame data is transferred to the TX/RX Controller.
8. When frame transmission is complete, if IEEE 1588 timestamping was enabled for the frame (as indicated in the transmit status) the timestamp value is written to the transmit descriptor (TDES6 and TDES7) that contains the end-of-frame buffer. The status information is then written to transmit descriptor TDES0. Because the OWN bit is cleared during this step, the CPU now owns this descriptor. If timestamping was not enabled for this frame, the DMA does not alter the contents of TDES6 and TDES7.
9. The Transmit Interrupt (TI) bit is set in the **EMACDMARIS** register after transmission completion of a frame that has Interrupt on Completion set in its last descriptor. The Interrupt on Completion bit resides in TDES0[30]. The DMA engine then returns to Step 3.
10. In the suspend state, the DMA tries to reacquire the descriptor (and thereby return to Step 3) when it receives a transmit poll demand in the **Ethernet MAC Transmit Poll Demand (EMACTXPOLL)** register, offset 0xC04, and the Underflow Interrupt Status (UNF) bit is cleared in the **EMACDMARIS** register. If the CPU stopped the DMA by clearing the ST bit of the **EMACDMAOPMODE** register, the DMA enters the STOP state.

Figure 24-7 on page 1611 shows the flow for the TX DMA default operation.

Figure 24-7. TX DMA Default Operation Using Descriptors

**TX DMA OSF Mode Operation**

While in the RUN state, the transmit process can simultaneously acquire two frames without closing the Status descriptor of the first if the **OSF** bit of the **EMACDMAOPMODE** register is set. As the transmit process finishes transferring the first frame, it immediately polls the transmit descriptor list

for the second frame. If the second frame is valid, the transmit process transfers this frame before writing the first frame's status information.

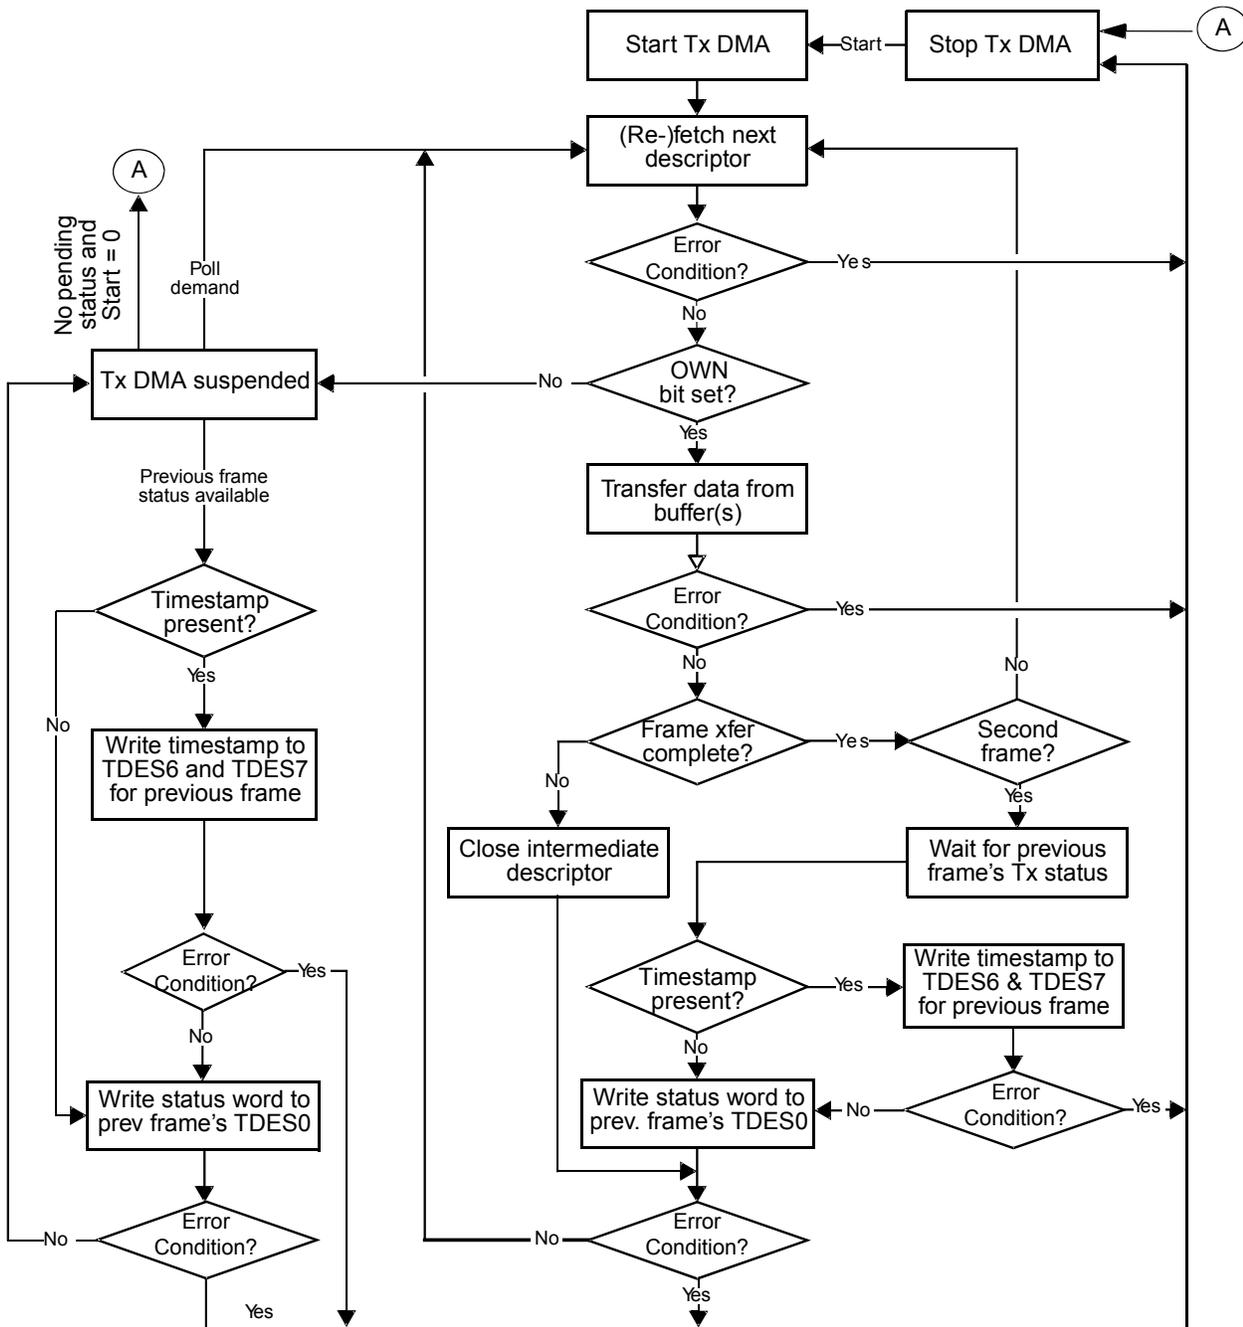

In Operate on Second Frame (OSF) mode, the RUN state TX DMA operates in the following sequence:

1. The DMA operates as described in Steps 1 to 6 (see page 1609).
2. Without closing the previous frame's last descriptor, the DMA fetches the next descriptor.
3. If the DMA owns the acquired descriptor, the DMA decodes the transmit buffer address in this descriptor. If the DMA does not own the descriptor, the DMA goes into SUSPEND mode and skips to 7.
4. The DMA fetches the Transmit frame from system memory and transfers the frame until the end-of-frame data is reached. It closes the intermediate descriptors if this frame is split across multiple descriptors.
5. The DMA waits for the previous frame's transmission status and timestamp. When the status is available, the DMA writes the timestamp to TDES6 and TDES7, if such timestamp was captured (as indicated by a status bit). The DMA then writes the status, with a cleared OWN bit, to the corresponding TDES0, thus closing the descriptor. If timestamping was not enabled for the previous frame, the DMA does not alter the contents of TDES6 and TDES7.
6. If enabled, the Transmit interrupt (TI) bit is set in the **EMACDMARIS** register, the DMA fetches the next descriptor and then proceeds to 3 (when Status is normal). If the previous transmission status shows an underflow error, the DMA goes into SUSPEND mode.
7. In SUSPEND mode, if a pending status and timestamp are received, the DMA writes the timestamp (if enabled for the current frame) to TDES6 and TDES7, then writes the status to the corresponding TDES0. It then sets relevant interrupts and returns to SUSPEND mode.
8. The DMA can exit SUSPEND mode and enter the RUN state only after receiving the Transmit Poll demand in the **EMACTXPOLL** register.

Note: The DMA fetches the next descriptor in advance before closing the current descriptor. Therefore, the descriptor chain should have more than two different descriptors for correct and proper operation.

Figure 24-8 on page 1613 shows the flow for the TX DMA Operate-On-Second-Frame (OSF) operation.

Figure 24-8. TX DMA OSF Mode Operation Using Descriptors

Transmit Frame Processing

The TX DMA expects that the data buffers contain complete Ethernet frames, excluding preamble, pad bytes, and Frame Check Sequence (FCS) fields. The Destination Address (DA), Source Address (SA), and Type/Length fields must contain valid data. If the Transmit Descriptor indicates that the MAC must disable CRC or PAD insertion, the buffer must have complete Ethernet frames (excluding preamble), including the CRC bytes. Frames can be data-chained and can span several buffers. Frames must be delimited by the First Segment Descriptor and the Last Segment Descriptor,

respectively. The First Descriptor bit is located at TDES0[28] and the Last Descriptor is located at TDES0[29].

As transmission starts, the First Descriptor must have TDES0[28] set. When this occurs, frame data transfers from the host memory buffer to the TX FIFO. Concurrently, if the current frame has the Last Segment Descriptor (TDES0[29]) clear, the transmit process attempts to acquire the next descriptor. The transmit process expects this descriptor to have TDES0[28] clear. If TDES0[29] is clear, it indicates an intermediary buffer. If TDES0[29] is set, it indicates the last buffer of the frame. After the last buffer of the frame has been transmitted, the DMA writes back the final status information to the Transmit Descriptor word of the descriptor that has the last segment bit set in Transmit Descriptor. At this time, if Interrupt on Completion (IC) bit is set, the **TI** bit in the **EMACDMARIS** register is set, the next descriptor is fetched and the process repeats.

The actual frame transmission begins after the TX FIFO has reached either the transmit threshold as configured by the **TTC** bit field of the **EMACDMAOPMODE** register, or a full frame is contained in the TX FIFO. To wait until there is a full frame in the TX FIFO the **TSF** bit in the **EMACDMAOPMODE** register must be set. Descriptors are released (**OWN** bit in the TDES0[31] cleared) when the DMA finishes transferring the frame.

Note: To ensure proper transmission of a frame and the next frame, the transmit descriptor that has the Last Descriptor bit (TDES0[29]) set, must specify a non-zero buffer size.

Transmit Polling Suspended

Transmit polling can be suspended by either of the following conditions:

- The DMA detects a descriptor owned by the CPU (TDES0[31]=0). To resume, the driver must give descriptor ownership to the DMA and then issue a Poll Demand command.
- A frame transmission is aborted when a transmit error because of underflow is detected. The appropriate Transmit Descriptor 0 (TDES0) bit is set.

If the DMA goes into SUSPEND state because of the first condition, then both the Normal Interrupt Summary (**NIS**) bit and the Transmit Buffer Unavailable (**TU**) bit are set in the **EMACDMARIS** register. If the second condition occurs, the Abnormal Interrupt Summary (**AIS**) bit and the Transmit Underflow (**UNF**) bit of the **EMACDMARIS** register are set and the information is written to Transmit Descriptor 0, causing the suspension.

In both cases, the position in the Transmit list is retained. The retained position is that of the descriptor following the last descriptor closed by the DMA. The driver must explicitly issue a Transmit Poll Demand command after rectifying the suspension case.

24.3.3.7 DMA Receive Operation

The following section describes the receive operation process.

Default Receive Operation

The RX DMA engine's reception sequence is as follows:

1. The host sets up receive descriptors (RDES0-RDES3) and sets the **OWN** bit (RDES0[31]).
2. When the **SR** bit of the **EMACDMAOPMODE** register is set, the DMA enters the **RUN** state. While in the **RUN** state, the DMA polls the Receive Descriptor list, attempting to acquire free descriptors. If the fetched descriptor is not free (is owned by the CPU), the DMA enters the **Suspend** state and jumps to Step 9.

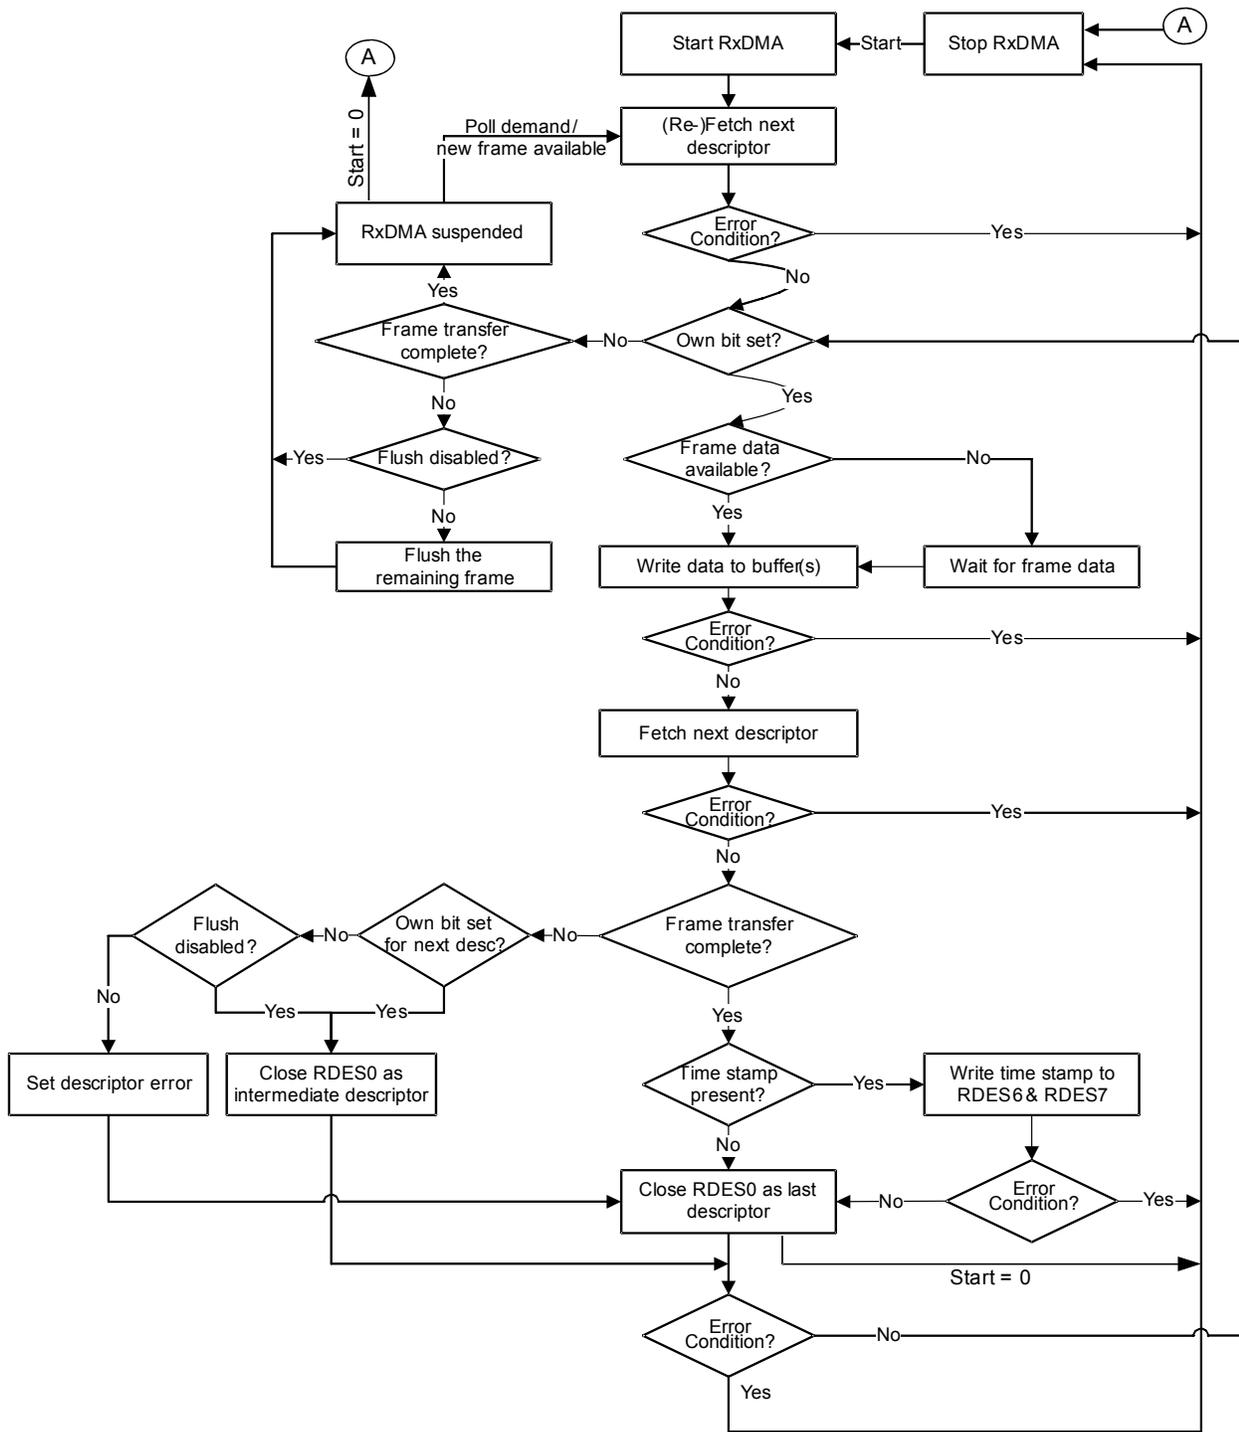

3. The DMA decodes the receive data buffer address from the acquired descriptors.
4. Incoming frames are processed and placed in the acquired descriptor's data buffers.
5. When the buffer is full or the frame transfer is complete, the RX DMA engine fetches the next descriptor.
6. If the current frame transfer is complete, the DMA proceeds to Step 7. If the DMA does not own the next fetched descriptor and the frame transfer is not complete (EOF is not yet transferred), the DMA sets the Descriptor Error (DE) bit in RDES0 (unless flushing is disabled through the `DFE` bit in the **EMACDMAOPMODE** register). The DMA closes the current descriptor (clears the OWN bit) and marks it as intermediate by clearing the Last Segment (LS) bit in the RDES0 value. If flushing is not disabled, then the DMA would mark it as the last descriptor. In either case, the DMA proceeds to Step 8. If the DMA does own the next descriptor but the current frame transfer is not complete, the DMA closes the current descriptor as intermediate and reverts to Step 4.
7. If IEEE 1588 timestamping is enabled, the DMA writes the timestamp to the current descriptor's RDES6 and RDES7. It then takes the receive frame's status and writes the status word to the current descriptor's RDES0, with the OWN bit cleared and the Last Segment (LS) bit set. If the host stopped the RX DMA by clearing the `SR` bit of the **EMACDMAOPMODE** register, DMA goes to the STOP state, otherwise the RX DMA proceeds to Step 8.
8. The RX DMA engine checks the last descriptor's OWN bit. If the CPU owns the descriptor (OWN bit is 0), the `RU` bit of the **EMACDMARIS** register is set and the DMA RX engine enters the SUSPEND state. If the DMA owns the descriptor, the engine returns to Step 4 and awaits the next frame.
9. Before the RX DMA engine enters the SUSPEND state, partial frames are flushed from the RX FIFO. Flushing can be controlled through the `DFE` bit of the **EMACDMAOPMODE** register.
10. The RX DMA enters the STOP state if the CPU has cleared the `SR` bit of the **EMACDMAOPMODE** register. Otherwise, it exits the SUSPEND state when a Receive Poll Demand is given or the start of the next frame is available from the RX FIFO. The DMA engine proceeds to Step 2 and re-fetches the next descriptor.

The DMA does not acknowledge accepting status from the TX/RX Controller until it has completed the timestamp write-back and is ready to perform status write-back to the descriptor.

If software has enabled timestamping through the **Ethernet MAC Timestamp Control (EMACTIMSTCTRL)** register, offset 0x700, when a valid timestamp is not available for the frame (for example, because the receive FIFO was full before the timestamp could be written to it), the DMA writes all-ones to RDES6 and RDES7. Otherwise if timestamping is not enabled, RDES6 and RDES7 remain unchanged.

Figure 24-9 on page 1616 shows the flow of a RX DMA Operation.

Figure 24-9. RX DMA Operation Flow

Receive Descriptor Acquisition

The Receive Engine always attempts to acquire an extra descriptor in anticipation of an incoming frame. Descriptor acquisition is attempted if any of the following conditions is satisfied:

- The `SR` bit of the **EMACDMAOPMODE** register has been set immediately after being placed in the RUN state.
- The data buffer or current descriptor is full before the frame ends for the current transfer.
- The controller has completed frame reception, but the current receive descriptor is not yet closed.
- The receive process has been suspended because of a host-owned buffer (`RDES0[31]=0`) and a new frame is received.
- A receive poll demand has been issued.

Receive Frame Processing

The MAC transfers the received frames to the system memory only when the frame passes the address filter and the frame size is greater than or equal to configurable threshold bytes set for the RX FIFO, or when the complete frame is written to the RX FIFO in store-and-forward mode.

If the frame fails the address filtering, it is dropped in the MAC block unless the Receive All (`RA`) bit is set in the **Ethernet MAC Frame Filter (EMACFRAMEFLTR)**, offset 0x004. If the `RA` bit is set, then the MAC passes all received frames. Frames that are shorter than 64 bytes, because of collision or premature termination, can be removed from the RX FIFO if the `DEF` bit is clear in the **EMACDMAOPMODE** register.

After 64 bytes have been received, the TX/RX Controller requests the DMA block to begin transferring the frame data to the receive buffer pointed by the current descriptor. The DMA sets the First Descriptor (`RDES0[9]`) bit to delimit the frame after the DMA Interface becomes ready to receive a data transfer (if DMA is not fetching transmit data from the system memory). The descriptors are released when the `OWN` (`RDES0[31]`) bit is reset to 0, either as the data buffer fills up or as the last segment of the frame is transferred to the receive buffer. If the frame is contained in a single descriptor, both Last Descriptor (`RDES0[8]`) and First Descriptor (`RDES0[9]`) are set.

The DMA fetches the next descriptor, sets the Last Descriptor (`RDES0[8]`) bit, and releases the `RDES0` status bits in the previous frame descriptor. Then the DMA sets the `RI` bit of the **EMACDMARIS** register. The same process repeats unless the DMA encounters a descriptor flagged as being owned by the host. If this occurs, the receive process sets the `RU` bit of the **EMACDMARIS** and enters the SUSPEND state. The position in the receive list is retained.

Receive Process Suspend

If a new receive frame arrives while the receive process is in SUSPEND state, the DMA refetches the current descriptor in the system memory. If the descriptor is now owned by the DMA, the receive process re-enters the RUN state and starts frame reception. If the descriptor is still owned by the CPU, by default, the DMA discards the current frame at the top of the RX FIFO and increments the missed frame counter. If more than one frame is stored in the RX FIFO, the process repeats. The discarding or flushing of the frame at the top of the RX FIFO can be prevented by disabling flushing through the `DEF` bit of the **EMACDMAOPMODE** register. In such conditions, the receive process sets the Receive Buffer Unavailable (`RU`) status and returns to the SUSPEND state.

24.3.3.8 DMA Interrupts

Interrupts can be generated as a result of various transfer events. The current status of interrupts can be read from the **EMACDMARIS** register and are enabled to trigger an interrupt through the programming of the **Ethernet MAC DMA Interrupt Mask (EMACDMAIM)** register. There are two groups of transfer event interrupts: Normal and Abnormal. The following lists the two groups:

- Normal Interrupts:
 - Transmit Interrupt (TI, bit 0): Indicates that frame transmission is complete.
 - Transmit Buffer Unavailable (TU, bit 2): Indicates the CPU owns the next descriptor in the transmit list and the DMA cannot acquire it.
 - Receive Interrupt (RI, bit 6): Indicates the frame reception is complete.
 - Early Receive Interrupt (ERI, bit 14): Indicates the DMA has filled the first half of the data buffer of the packet
- Abnormal Interrupts:
 - Transmit Process Stopped (TPS, bit 1): Indicates transmission is stopped.,
 - Transmit Jabber Timeout (TJT, bit 3): Indicates the Transmit Jabber Timer expired.
 - Receive FIFO Overflow (OVF, bit 4): Indicates the receive buffer had an overflow during frame reception.
 - Transmit Underflow (UNF, bit 5): Indicates the transmit buffer had an underflow during frame transmission.
 - Receive Buffer Unavailable (RU, bit): Indicates the CPU owns the next descriptor in the receive list and the DMA cannot acquire it.
 - Receive Process Stopped (RPS, bit 8): Indicates the receive process entered the STOP state.
 - Receive Watchdog Timeout (RWT, bit 9): Indicates a frame length greater than 2 KB is received (10,240 when Jumbo Frame is enabled)
 - Early Transmit Interrupt (ETI, bit 10): Indicates a frame to be transmitted is fully transferred to the TX FIFO.
 - Fatal Bus Error (FBI, bit 13): Indicates a bus error occurred.

Any of the interrupts in the Normal Interrupt group that are enabled in the **EMACDMAIM** register are ORed together to create the Normal Interrupt Summary (NIS) bit in the **EMACDMARIS** register. Any of the interrupts in the Abnormal Interrupt group that are enabled in the **EMACDMAIM** register are ORed together to create the Abnormal Interrupt Summary (AIS) bit in the **EMACDMARIS** register. Interrupts are cleared by writing a 1 to the corresponding bit position in the **EMACDMARIS** register. When all enabled interrupts within a group are cleared, the corresponding summary bit is cleared.

Interrupts are not queued and if the interrupt event occurs again before the driver has responded to it, no additional interrupts are generated. An interrupt is only generated once for simultaneous, multiple events. The driver must read the **EMACDMARIS** register for the cause of the interrupt.

The **Ethernet MAC Receive Interrupt Watchdog Timer (EMACRXINTWDT)** register, offset 0xC24 can be used to control the Receive Interrupt (RI) assertion. If the RDES1[31] bit (Receive Interrupt) bit has not been set in the receive descriptor and the **EMACRXINTWDT** register is programmed with a non-zero value, it gets activated as soon as the RX DMA completes a transfer of a received frame to system memory without asserting the receive interrupt. When this counter runs out as per the programmed value, the RI bit is set in the **EMACDMARIS** register and the interrupt is asserted

if the corresponding `RI` bit is enabled in the **EMACDMAIM** register. This counter gets disabled before it runs out if a frame is transferred to memory and the `RI` bit is set because it is enabled for that descriptor.

24.3.3.9 DMA Bus Error

If an internal bus error occurs during a DMA transfer, the fatal bus error (`FBI`) interrupt is set in the **EMACDMARIS** register and the Access Error status (`AE`) bit field in the **EMACDMARIS** register indicates the type of error that caused the bus error. The DMA controller can resume operation only after soft resetting the Ethernet MAC and the re-initializing the DMA.

24.3.4 TX/RX Controller

The TX/RX Controller consists of a FIFO memory which buffers and regulates the frames between the system memory and the MAC. It also controls the data transferred between clock domains. Both the transmit and receive data paths are 32-bits wide. The TX FIFO and RX FIFO are each 2 KB in depth.

At reset, the TX/RX Controller is configured and ready to manage data flow to and from the DMA to the MAC. Note that the DMA and MAC must be initialized by the application out of reset.

24.3.4.1 Transmit (TX) Control Path

The DMA controller is used for all Ethernet transmissions. The Ethernet frames are read from memory and transferred to the TX FIFO by the DMA. When the MAC is available, the frame is transferred from the FIFO. When the end-of-frame (EOF) is transferred, the MAC notifies the DMA the status of the transmission.

The TX FIFO has a depth of 2 KB. The FIFO fill level has the capability of triggering the DMA to initiate a burst transfer. The DMA also transfers start-of-frame (SOF), end-of-frame (EOF), CRC and pad-insertion information to the TX/RX Controller so that this information can be passed to the MAC when it is ready for transmission from the TX FIFO.

Data can be transmitted to the MAC in threshold mode or store-and-forward mode. If the `TTC` field is configured in the **Ethernet MAC DMA Operation Mode (EMACDMAOPMODE)** register at offset `0xC18` and the `TSF` bit in the same register is `0x0`, then the TX Controller is operating in threshold mode. In this mode, the data is transferred to the MAC when the number of bytes in the FIFO crossed the value configured in the `TTC` bit field or when the end-of-frame is written before the threshold is crossed. In store-and forward mode, the `TTC` bit field is configured and the `TSF` bit is set. Data is transferred to the MAC only when one or more of the following conditions are true:

- A complete frame is stored in the FIFO
- The TX FIFO becomes almost full
- The TX FIFO does not have space to accommodate the requested burst length

With these conditions, the TX Controller continues store-and-forward mode even if the Ethernet frame length is bigger than the TX FIFO size.

The TX FIFO can be flushed of all contents by setting the `FTF` bit in the **EMACDMAOPMODE** register. This bit is self-clearing and initializes the FIFO pointers to the default state. If the `FTF` bit is set during a frame transfer from the TX Controller to the MAC, then the TX Controller stops further transfer. Early termination of the transfer causes a underflow event and this status is communicated to the DMA.

Transmit Operation

During a transmit, single-packet or double-packets can reside in the buffer. The following describes the details of each:

- **Single-packet transmit:** During single packet transmission, the DMA controller fetches data from the CPU memory and forwards it to the TX FIFO and continues to receive data until the end-of-frame is transferred. The data is transmitted from the TX FIFO to the MAC by the TX/RX Controller when the threshold level is crossed or a full packet of data is received into the TX FIFO. When the TX/RX Controller receives acknowledgment from the MAC that it has received the EOF, it notifies the DMA so another transmit can begin.
- **Two-packet transmit:** Because the DMA must update the descriptor status before releasing it to the CPU, there can be at most two frames inside a transmit FIFO. The second frame is fetched by the DMA and put into the TX FIFO only if the `OSF` bit is set in the **EMACDMAOPMODE** register at offset `0xC18`. If this bit is not set, the next frame is fetched from memory only after the MAC has completely processed the frame and the DMA has released the descriptors.

If the `OSF` bit is set, the DMA starts fetching the second frame immediately after completing the transfer of the first frame to the FIFO. It does not wait for the status to be updated. The TX/RX Controller receives the second frame into the FIFO while transmitting the first frame. As soon as the first frame has been transferred and the status is received from the MAC, the TX/RX Controller sends the acknowledgement to the DMA. If the DMA has already completed sending the second packet to the TX/RX Controller, it must wait for the status of the first packet before proceeding to the next frame.

Collision and Retransmission

If a collision occurs at the MAC application interface while the TX/RX Controller is transferring data to the MAC, the transmission is aborted and the MAC indicates a retry attempt by giving a collision status before the EOF is transferred to the TX/RX Controller from the DMA. This enables the TX/RX Controller to retry transmission of the frame data from the FIFO.

After more than 96 bytes are transferred to the MAC, the FIFO controller clears space in the FIFO and makes it available to the DMA to transfer more data. Retransmission is not possible after this threshold is crossed or when the MAC indicates a late collision event.

When a frame transmission is aborted because of underflow and a collision event follows, which initiates a retry, then the retry has higher priority than the abort.

TX FIFO Flush Operation

The TX FIFO can be flushed by setting the `FTF` bit in the **EMACDMAOPMODE** register. The flush operation is immediate and the TX/RX Controller clears the TX FIFO and the corresponding pointers to the initial state even if it is in the middle of transferring a frame to the MAC. The data which is already accepted by the MAC transmitter is not flushed. This data is scheduled for transmission and results in an underflow event because the TX FIFO did not complete the transfer or the rest of the frame. As in all underflow conditions, a runt frame is transmitted and observed on the line. The status of such a frame is marked with both underflow and frame flush events in the Transmit Descriptor 0 (TDES0) word.

The TX/RX Controller also stops accepting any data from the DMA during the flush operation. It generates and transfers Transmit Status Words to the application for the frames that are flushed inside the FIFO, including partial frames. Frames that are completely flushed in the TX/RX Controller are identified by setting the Flush Status (FF) bit in the Transmit Descriptor 0 (TDES0) word. The TX/RX Controller completes the flush operation when the DMA accepts all of the status words for

the frames that were flushed and then clears the TX FIFO Flush control (FTF) bit in the **EMACDMAOPMODE** register. At this point, the TX/RX Controller starts accepting new frames from the DMA.

Transmit Status Word

At the end of the transfer of the Ethernet frame to the MAC and after the MAC completes the transmission of the frame, the TX/RX delivers a transmit status word (TDES0) to the application. If IEEE timestamping is enabled, the TX/RX Controller returns the specific frame's 64-bit timestamp, along with the transmit status word. The fields for the Transmit Descriptors are described in "Enhanced and Alternate Descriptors" on page 1598.

24.3.4.2 Receive (RX) Control Path

TX/RX Controller receives frames from the MAC and pushes them into the RX FIFO. When the fill level of the RX FIFO crosses the programmed RX Threshold, the DMA is notified.

Receive Operation

During a receive operation the TX/RX Controller is a slave to the MAC. The steps of the receive operation are as follows:

1. The MAC receives a frame. This data, along with SOF, EOF and byte enable information is sent to the TX/RX Controller. The TX/RX Controller accepts the data and pushes it into the RX FIFO. After the EOF is transferred, the MAC drives the status word, which is also pushed in to the RX FIFO.
2. When timestamp is enabled by setting the **TSEN** bit in the **Ethernet MAC Timestamp Control (EMACTIMSTCTRL)** register, at offset 0x700, and the 64-bit timestamp is present with the receive status, it is appended to the frame and received by the MAC and pushed into the TX FIFO before the corresponding receive status word is written. Thus, two additional locations per frame are taken for storing timestamp in the RX FIFO.
3. Data can be sent to the TX/RX Controller in cut-through mode or store-and-forward mode. When the **RTC** bit field of the **EMACDMAOPMODE** register is set to 0x0 and cut-through mode is enabled (**RSF=0**), the TX/RX Controller indicates availability to transfer to the DMA when 64 bytes are in the RX FIFO or a full packet of data has been received into the RX FIFO. When the DMA initiates transfers to system memory, the TX/RX Controller continues to transfer data from the RX FIFO until a complete packet has been transferred. When EOF has occurred, the TX/RX Controller sends the status word to the DMA.

Note: The timestamp transfer takes two clock cycles and the lower 32-bits of the timestamp are sent first when timestamping is enabled.

When the **RSF** bit is set in the **EMACDMAOPMODE** register, RX FIFO store-and-forward mode is enabled and a frame is read by the DMA only after it is completely written into the RX FIFO. In this mode, only valid frames are read and forwarded to the application. In cut-through mode, some error frames are not dropped because the error status is received at the end of the frame and by that time the start of that frame has already been read out of the RX FIFO.

The TX/RX Controller is capable of storing any number of frames in the RX FIFO as long as it is not full.

Error Handling

If the RX FIFO is full before it receives the EOF data from the MAC, an overflow is declared, the entire frame (including the status word) is dropped and the **Ethernet MAC Missed Frame and Buffer Overflow Counter (EMACMFBOC)** register is incremented. These error actions occur even if the `FEF` bit is set in the **EMACDMAOPMODE** register. If the start address of such a frame has already been transferred to the TX/RX Controller, the rest of the frame is dropped and a dummy EOF is written to the FIFO along with its status word. The descriptor status indicates a partial frame because of overflow. In such frames, the Frame Length (FL) field in the receive descriptor is invalid. If the RX FIFO is configured to operate in the store-and-forward mode and if the length of the received frame is more than the FIFO size, overflow occurs and all such frames are dropped. During error handling, the DMA flushes the error frame currently being read.

The Receive control logic can filter error and undersized frames if enabled through configuring the `FEF` or `FUF` bit of the **EMACDMAOPMODE** register. Filtering must be set before the start address of the frame has been transferred to the TX/RX controller for it to take effect.

Receive Word Status

At the end of an Ethernet frame transfer to the system memory, the TX/RX Controller sends a receive status word, `RDES0`, to the application. Until the end of the frame transfer, the TX/RX Controller stores the status and frame length in an asynchronous status FIFO whose depth is determined by the size of the RX FIFO (2K) and the minimum size of the frame. If the frame size is 64, then the asynchronous FIFO depth is $2048/64 = 32$ bytes in length. Note that when the status of a partial frame (because of overflow) is sent to the application, the Frame Length field of `RDES0` is not valid and is set to zero.

Note: When the timestamp feature is enabled, the receive status field is greater than 32-bits. An extended status bit-field [63:32] provides information about the received Ethernet payload when it is carrying PTP packets or TCP/UDP/ICMP over IP packets. Since the data bus is 32 bits, the status is transferred over two clock cycles.

24.3.4.3 MAC Flow Control

Flow control mechanisms can be enabled for both the TX and RX FIFO datapath, depending on the configurations in the **Ethernet MAC Flow Control (EMACFLOWCTL)** register at offset 0x018 and the `DUPM` bit configuration in the **Ethernet MAC Configuration (EMACCFG)** register at offset 0x000.

Table 24-17. TX MAC Flow Control

| TFE bit in EMACFLOWCTL | DUPM bit in EMACCFG | Description |
|------------------------|---------------------|---|
| 0 | X | The MAC transmitter does not perform the flow control or backpressure operation. |
| 1 | 0 | The MAC transmitter performs backpressure when the <code>FCBBPA</code> bit in the Ethernet MAC Flow Control (EMACFLOWCTL) register is set. |
| 1 | 1 | The MAC transmitter sends a pause frame when the <code>FCBBPA</code> bit in the Ethernet MAC Flow Control (EMACFLOWCTL) register is set. |

Table 24-18. RX MAC Flow Control

| TFE bit in EMACFLOWCTL | DUPM bit in EMACCFG | Description |
|------------------------|---------------------|--|
| 0 | X | The MAC receiver does not detect the received Pause frames. |
| 1 | 0 | The MAC receiver does not detect the received Pause frames but recognizes such frames as Control frames. |

Table 24-18. RX MAC Flow Control (continued)

| TFE bit in EMACFLOWCTL | DUPM bit in EMACCFG | Description |
|------------------------|---------------------|---|
| 1 | 1 | The MAC receiver detects or processes the Pause frames and responds to such frames by stopping the MAC transmitter. |

24.3.5 MAC Operation

The MAC module enables the CPU to transmit and receive data over Ethernet in compliance with the IEEE 802.3-2008 standard. The MAC supports the interface to the PHY and is comprised of a receive and transmit module whose features are described in the following sections.

24.3.5.1 MAC Transmit Module

MAC transmission is initiated when the TX/RX Controller transmits data with the start of frame (SOF) signal asserted. When the SOF signal is detected, the MAC accepts the data and begins transmitting to the PHY. The time required to transmit the frame data after the application initiates transmission varies, depending on delay factors like inter-frame gap (IFG) delay, time to transmit preamble or start of frame data (SFD), and any back-off delays for half-duplex mode. Until then, the MAC does not accept data received from the TX/RX Controller.

After the end-of-frame (EOF) is transferred to the MAC, the MAC completes the normal transmission and gives the status of transmission to the TX/RX Controller. If a normal collision (in half-duplex mode) occurs during transmission, the MAC conveys the transmit status to the TX/RX Controller. It then accepts and drops all further data until the next SOF is received. The TX/RX Controller should retransmit the same frame from SOF on observing a retry request (in the transmit status word) from the MAC. The MAC issues an underflow status if the TX/RX Controller is not able to provide the data continuously during the transmission. During the normal transfer of a frame from the TX/RX Controller, if the MAC receives an SOF without getting an EOF for the previous frame, it ignores the SOF and considers the new frame as a continuation of the previous frame.

If the number of bytes received from memory is less than 60 bytes, zeros are automatically appended to the transmitting frame to make the data length exactly 46 bytes to meet the minimum data field requirement of IEEE802.3.

The transmit engine controls the operation of Ethernet frame transmission. Some of the functions of the transmit module include:

- Output of (32-bit) Transmit Status (TDES0) to the application at the end of normal transmission or collision
- Generating preamble and Start of Frame Data (SFD)
- Generating jam pattern in half-duplex mode
- Supporting Jabber time-out
- Supporting flow control
- Generating timestamp information for transmission
- Scheduling frame transmission to satisfy inter-frame gap (IFG) and back-off delays
- Generating CRC and FCS field for Ethernet Frame
- Generating pause frames as necessary in full duplex mode

When a new frame transmission is requested, the MAC transmit module sends out a preamble and SFD, followed by the data in the TX FIFO. The preamble is defined as 7 bytes of 0xAA and the SFD is defined as 1 byte of 0xAB pattern.

The collision window is defined as 1 slot time (512-bit times). If a collision occurs any time from the beginning of the frame to the end of the CRC field, the MAC transmit module sends a 32-bit jam pattern of 0x5555.5555 to inform all other stations that a collision has occurred. If the collision is seen during the preamble transmission phase, the MAC transmit module completes the transmission of the preamble and SFD, and then sends the jam pattern. If the collision occurs after the collision window and before the end of the FCS field, the MAC transmit module sends a 32-bit jam pattern and sets the late collision bit in the transmit frame status. The jam pattern generation is applicable only to half-duplex mode.

A jabber timer is enabled by default at reset in the MAC module. If the `JD` bit in the **EMACCFG** register at offset 0x000 is clear and the MAC module has transferred more than 2K bytes, the jabber timer causes the MAC module to stop transmission of Ethernet frames. The timeout is changed to 10 KB when the Jumbo Frame Enable (`JFEN`) bit is enabled in the **EMACCFG** register.

The MAC transmit module uses a deferral mechanism for flow control (back pressure) in half-duplex mode. When the application requests to stop receiving frames, the transmit module sends a jam pattern of 32 bytes whenever it senses the reception of a frame, provided the transmit flow control is enabled. This results in a collision and the remote station backs off. If the application requests a frame to be transmitted, the frame is scheduled and transmitted even when backpressure is activated. If the backpressure is activated for a long time (more than 16 consecutive collision events occur) then the remote stations abort their transmissions because of excessive collisions.

If IEEE 1588 timestamping is enabled for the transmit frame, the MAC transmit module takes a snapshot of the system time when the start-of-frame data is output on the bus.

24.3.5.2 MAC Transmit Module CRC Generator

The Transmit CRC Generator is used to generate the 32-bit CRC for the FCS field of the Ethernet frame. The encoding is defined by the following generating polynomial:

$$G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x^1.$$

The calculated CRC is valid on the next clock after the data is received.

24.3.5.3 MAC Receive Module

A receive operation is initiated when the MAC detects start-of-frame data (SFD). The MAC strips the preamble and SFD before proceeding to process the frame. The header fields are checked for the filtering and the FCS field is used to verify the CRC for the frame. The received frame is stored in a buffer until the address filtering is performed. The frame is dropped in the MAC if it fails the address filter.

Some of the functions of the MAC receive module are as follows:

- Stripping the preamble, SFD and carrier extension of the Ethernet frame
- Providing IEEE 1588 timestamping whenever an SFD is detected
- Converting receive nibble data into bytes in MII mode
- Decoding Length/Type field of the Ethernet frame
- Auto-CRC/pad stripping if enabled in the **EMACCFG** register

- Frame data and status buffering for received frames
- Data path conversion of 8-bit data to 32-bit data
- Frame filtering
- Attaching calculated IP checksum input to frame
- Detecting receiving pause frames and pausing the frame transmission for the delay specified withing the received pause frame
- Receive IP Checksum Verification
- Performing destination and source address checking functions on all received frames and reporting the address filtering status to the receive frame controller module.

24.3.5.4 MAC Receive Module CRC Generator

The receive CRC Generator is used to generate the 32-bit CRC for the FCS field of the Ethernet frame. The encoding is defined by the following generating polynomial:

$$G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

The calculated CRC is valid on the next clock after the data is received.

24.3.5.5 MAC Receive Frame Controller

If the **RA** bit is set in the **Ethernet MAC Frame Filter (EMACFRAMEFLTR)** register, offset 0x004, the MAC Receive Frame Controller initiates the data transfer to the RX FIFO as soon as four bytes of Ethernet data are received. At the end of the data transfer, the received frame status that includes the frame filter bits (SA or DA filter fail) and status are also sent. These bits indicate to the application whether the received frame has passed the filter controls. This module does not drop any frame on its own in this mode.

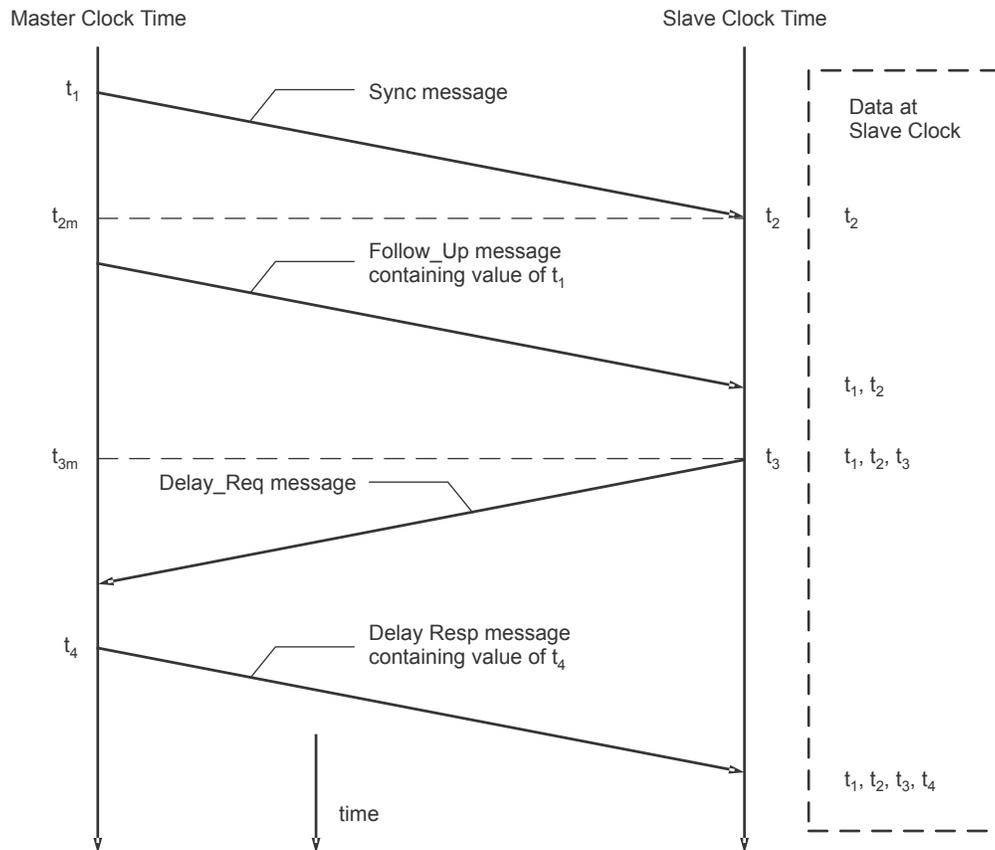

If the **RA** bit is clear, the MAC Receive Frame Controller performs frame filtering based on the destination/source address (the application still needs to perform another level of filtering if it decides not to receive any bad frames like runt, CRC error frames, etc.) After receiving the destination or source address bytes, the MAC Receive Frame Controller checks the filter-fail sign for an address match. On detecting a filter-fail, the frame is dropped and not transferred to the application.

Note: When the PMT module is configured for power-down mode, all received frames are dropped and not forwarded to the application.

24.3.6 IEEE 1588 and Advanced Timestamp Function

The MAC module supports the IEEE 1588-2002 Timestamp Precision Time Protocol (PTP) and the IEEE 1588-2008 Advanced Timestamp features. PTP enables precise synchronization of clocks in measurement and control systems implemented with technologies such as network communication, local computing, and distributed objects. The PTP applies to systems communicating by a local area network supporting multicast messaging. This protocol enables heterogeneous systems that include clocks of varying inherent precision, resolution, and stability to synchronize. The protocol supports system-wide synchronization accuracy in the sub-microsecond range with minimal network and local clock computing resources.

The PTP is transported over UDP/IP. The system or network is classified into master and slave nodes for distributing the timing and clock information. Figure 24-10 on page 1626 shows the process that PTP uses for synchronizing a slave node to a master node by exchanging PTP messages.

Figure 24-10. Networked Time Synchronization

As shown in Figure 24-10 on page 1626, the PTP uses the following process:

1. The master broadcasts the PTP Sync messages to all its nodes. The Sync message contains the master's reference time information. The time at which this message leaves the master's system is t_1 . This time is captured at the MII interface.
2. The slave receives the Sync message and also captures the exact time, t_2 , using its timing reference.
3. The master sends a Follow_Up message to the slave, which contains t_1 information for later use.
4. The slave sends a Delay_Req message to the master, noting the exact time, t_3 , at which this frame leaves the MAC.
5. The master receives the message, capturing the exact time, t_4 , at which it enters its system.
6. The master sends the t_4 information to the slave in the Delay_Resp message.
7. The slave uses the four values of t_1 , t_2 , t_3 , and t_4 to synchronize its local timing reference to the master's timing reference.

Most of the PTP implementation is done in the software above the UDP layer. However, the hardware support is required to capture the exact time when specific PTP packets enter or leave the Ethernet

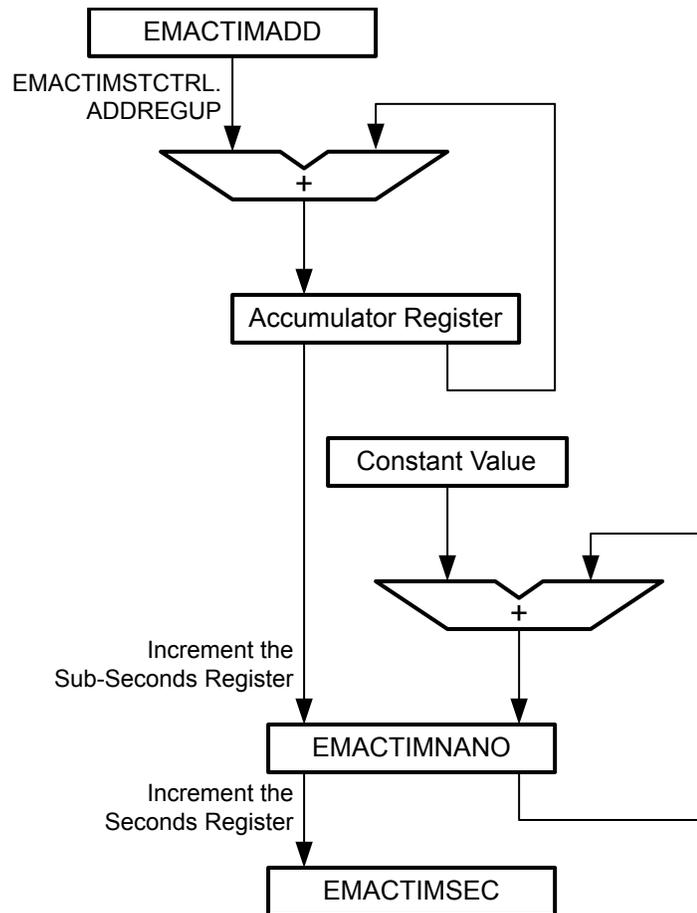

MAC. This timing information is captured and returned to the software for the proper implementation of PTP with high accuracy.

24.3.6.1 System Time Module

The System Time module maintains a 64-bit time and is updated using the MOSC clock source as the PTP clock reference. This time is the source for taking snapshots (timestamps) of the Ethernet frames being transmitted or received. Two methods of updating the system time counter are implemented. The counter can be initialized or corrected using the coarse correction method. In this method, the initial value or the offset value is written to the **MAC System Time - Seconds Update (EMACTIMSECU)** register along with the **MAC System Time - Nanoseconds Update (EMACTIMNANOU)** register. For initialization the system time counter is written with the value in these registers, while for system time correction, the offset value is added to or subtracted from the system time.

In the fine correction method, the slave clock's frequency drift with respect to the master clock is corrected over a period of time instead of in one clock, as in coarse correction. This helps maintain linear time and does not introduce drastic changes (or a large jitter) in the reference time between PTP Sync message intervals. In this method, an accumulator sums up the contents of the **EMACTIMADD** register, as shown in Figure 24-11 on page 1628. The arithmetic carry that the accumulator generates is used as a pulse to increment the system time counter. The accumulator and the addend are 32-bit registers. Here, the accumulator acts as a high precision frequency multiplier or divider.

Figure 24-11. System Time Update Using Fine Correction Method

Note: If the Ethernet Controller is configured to use the MII/RMII interface to an external PHY, then the MOSC clock that feeds the PTP reference clock to the System Time Module has a minimum frequency requirement of 5 MHz and a maximum frequency of 25 MHz. For coarse correction methods, the value of MOSC can be anywhere within this range, but for the fine correction method, a 25 MHz value MOSC crystal should be used for the best accuracy. If the Ethernet Controller is configured to use the MII interface connected to the integrated PHY, then the MOSC clock that feeds the PTP reference clock to the System Time Module must be 25 MHz because it also clocks the integrated PHY module.

Initially, the Ethernet's slave clock (from the MOSC) is adjusted with a compensation value (as described in the previous paragraph) which is written to the Timestamp Addend Register ($TSAR$) field in the **EMACTIMADD** register. This value is calculated as: $\text{FreqCompensationValue}_0 = TSAR = 2^{32} / \text{FreqDivisionRatio}$.

The System Time Module requires a 20-MHz PTP reference clock frequency to achieve 50-ns accuracy in the fine correction method. An addend must be written to the **Ethernet MAC Time Stamp Addend (EMACTIMADD)** register, offset 0x718 to achieve timing synchronization. If the MOSC clock source is 25 MHz, the frequency division ratio (FreqDivisionRatio) of the two is calculated as $25 \text{ MHz} / 20 \text{ MHz} = 1.25$. Hence, the default addend value to be set in the register is $2^{32} / 1.25$ or 0xCCCC.CCD0. If the reference clock drifts lower, to 24 MHz for example, the ratio is $24 / 20$, or 1.2 and the value to set in the addend register is $2^{32} / 1.20$, or 0xDFF1.65D2. The software must

calculate the drift in frequency based on the Sync messages and update the **EMACTIMADD** register, at offset 0x718, accordingly.

If the master to slave delay is initially assumed to be the same for consecutive Sync messages, then the following steps can be used to calculate a new TSAR value. The following algorithm calculates the precise master to slave delay value to allow for re-synchronization with the master using the new value:

1. At time MasterSyncTime_n the master sends the slave clock a Sync message. The slave receives this message when its local clock is SlaveClockTime_n and computes MasterClockTime_n as:

$$\text{MasterClockTime}_n = \text{MasterSyncTime}_n + \text{MasterToSlaveDelay}_n$$
2. The master clock count, $\text{MasterClockCount}_n$, for the current Sync cycle is given by:

$$\text{MasterClockCount}_n = \text{MasterClockTime}_n - \text{MasterClockTime}_{n-1}$$

This assumes that the $\text{MasterToSlaveDelay}$ is the same for Sync cycles n and $n-1$.
3. The slave clock count for current Sync cycle, SlaveClockCount_n is given by:

$$\text{SlaveClockCount}_n = \text{SlaveClockTime}_n - \text{SlaveClockTime}_{n-1}$$
4. The difference between the master and slave clock counts for the current Sync cycle, ClockDiffCount_n , is given by:

$$\text{ClockDiffCount}_n = \text{MasterClockCount}_n - \text{SlaveClockCount}_n$$
5. The frequency-scaling factor for the slave clock, FreqScaleFactor_n is given by:

$$\text{FreqScaleFactor}_n = (\text{MasterClockCount}_n + \text{ClockDiffCount}_n) / \text{SlaveClockCount}_n$$
6. The frequency compensation value, $\text{FreqCompensationValue}$, to be written in the TSAR field of the **EMACTIMADD** register is:

$$\text{FreqCompensationValue}_n = \text{FreqScaleFactor}_n * \text{FreqCompensationValue}_{n-1}$$

In theory, this algorithm achieves lock in one Sync cycle; however, it may take several cycles, because of changing network propagation delays and operating conditions. This algorithm is self-correcting: if for any reason the slave clock is initially set to a value from the master that is incorrect, the algorithm corrects it at the cost of more Sync cycles.

24.3.6.2 Transmit Timestamping

The MAC captures a timestamp when the Start Frame Delimiter (SFD) of a frame is sent. The transmit frames are marked to indicate whether a timestamp should be captured for that frame and written to the extended transmit descriptors that support timestamping. The MAC returns the timestamp automatically to the corresponding transmit descriptor, thus connecting the timestamp with the specific PTP frame. The 64-bit timestamp information is written to the TDES6 and TDES7 fields.

24.3.6.3 Receive Timestamping

The MAC captures the timestamp of all received frames. The MAC does not process the received frames to identify the PTP frames in default timestamping mode (when Advanced Timestamp is disabled). The MAC gives the timestamp and the corresponding status to the TX/RX Controller along with the EOF data. The TX/RX Controller validates and indicates the availability of the timestamp so that the DMA can return the timestamp to the corresponding receive descriptor. The

64-bit timestamp information is written to the RDES6 and RDES7 fields. The timestamp is written only to the receive descriptor for which the Last Descriptor status field has been set to 1 (the EOF marker). When the timestamp is not available (for example, because of an RX FIFO overflow), an all '1s' pattern is written to the descriptors (RDES6 and RDES7), indicating that the timestamp is not correct. If timestamping is disabled, the DMA does not alter RDES6 or RDES7. RDES0[7] indicates whether the timestamp is updated in RDES6 and RDES7.

24.3.6.4 Timestamp Error Margin

According to the IEEE 1588 specifications, a timestamp must be captured at the SFD of the transmitted and received frames at the MAC interface. Because the reference timing source, MOSC, is taken as different from MAC reference clocks, a small error margin is introduced, because of the transfer of information across asynchronous clock domains. In the transmit path, the captured and reported timestamp has a maximum error margin of 2 PTP (MOSC) clocks. It means that the captured timestamp has the reference timing source (MOSC) value that is given within 2 clocks after the SFD has been transmitted to the PHY. Similarly, in the receive path, the error margin is 3 MAC reference clocks, plus up to 2 PTP clocks. The error margin of the three MAC reference clocks can be ignored by assuming that this constant delay is present in the system (or link) before the SFD data reaches the interface of MAC.

Note: When the Ethernet Controller is configured to use the MII interface to an external PHY, the MII clock is provided by the external PHY through `ENORXCK` and `ENOTXCK`. When the Ethernet Controller is connected to the integrated PHY, the reference clock must be 25 MHz because it is also the source to the PHY.

Note: When IEEE 1588 timestamping is enabled with internal timestamp, use a PTP clock frequency that is greater than 5 MHz. This is because the `SSINC` field in the `EMACSUBSECINC` register limits the PTP frequency that can be used to ~4 MHz.

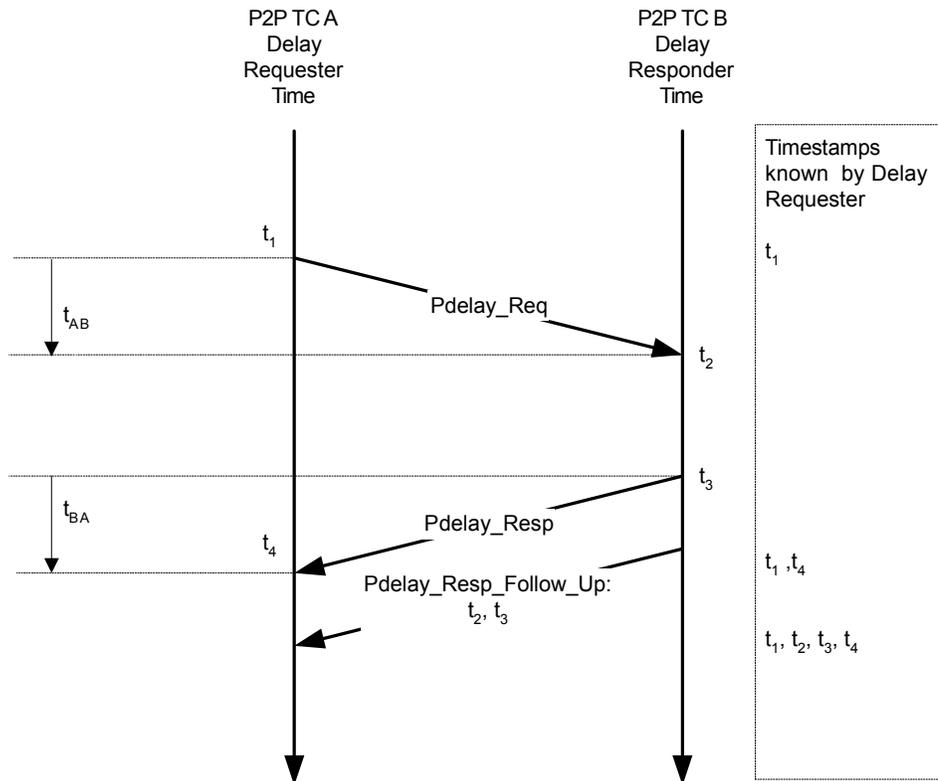

24.3.6.5 IEEE 1588-2008 Advanced Timestamps

In addition to the basic timestamp features mentioned in IEEE 1588-2002 Timestamps, the Ethernet Controller supports the following advanced timestamp features defined in the IEEE 1588-2008 standard:

- Supports the IEEE 1588-2008 (version 2) timestamp format.
- Provides an option to take snapshot of all frames or only PTP type frames.
- Provides an option to take snapshot of only event messages.
- Provides an option to take the snapshot based on the clock type: ordinary, boundary, end-to-end, and peer-to-peer.
- Provides an option to select the node to be a master or slave clock.
- Identifies the PTP message type, version, and PTP payload in frames sent directly over Ethernet and sends the status.
- Provides an option to measure sub-second time in digital or binary format.

Peer-to-Peer Transparent Clock Message Support

The IEEE 1588-2008 version supports Peer-to-Peer PTP (Pdelay) message in addition to SYNC, Delay Request, Follow-up, and Delay Response messages. Figure 24-12 on page 1631 shows the method to calculate the propagation delay in clocks supporting peer-to-peer path correction.

Figure 24-12. Propagation Delay Calculation in Clocks Supporting Peer-to-Peer Path Correction

As shown in Figure 24-12 on page 1631, the propagation delay is calculated in the following way:

1. Port-1 issues a $Pdelay_Req$ message and generates a timestamp, t_1 , for the $Pdelay_Req$ message.
2. Port-2 receives the $Pdelay_Req$ message and generates a timestamp, t_2 , for this message.
3. Port-2 returns a $Pdelay_Resp$ message and generates a timestamp, t_3 , for this message.
To minimize errors because of any frequency offset between the two ports, Port-2 returns the $Pdelay_Resp$ message as quickly as possible after the receipt of the $Pdelay_Req$ message. The Port-2 returns any one of the following:
 - The difference between the timestamps t_2 and t_3 in the $Pdelay_Resp$ message.
 - The difference between the timestamps t_2 and t_3 in the $Pdelay_Resp_Follow_Up$ message.
 - The timestamps t_2 and t_3 in the $Pdelay_Resp$ and $Pdelay_Resp_Follow_Up$ messages respectively.
4. Port-1 generates a timestamp, t_4 , on receiving the $Pdelay_Resp$ message.
5. Port-1 uses all four timestamps to compute the mean link delay.

Advanced Timestamp Supported Clock Types

The Advance Timestamp Module supports an ordinary clock as defined by the IEEE 1588-2008 standard. The characteristics of this clock is as follows:

- Sending and receiving of PTP messages. The timestamp snapshot can be controlled through the **Ethernet MAC Timestamp Control (EMACTIMSTCTRL)** register, offset 0x700. Timestamp snapshots can be for Sync messages.
- Maintaining the data sets such as timestamp values.

For an ordinary clock, snapshots can be taken of either version 1 or version 2 PTP types but not both. Selecting between the two is controlled by the `PTPVER2` bit of the **EMACTIMSTCTRL** register.

PTP Processing and Control

There are fields in an Ethernet Payload that the Ethernet Controller can use to detect the PTP packet type and control the snapshot to be taken. These fields are different depending on whether the PTP frames are:

- PTP frames over IPv4
- PTP frames over IPv6
- PTP frames over Ethernet

The `PTPIPv4`, `PTPIPv6` or `PTPETH` bits can be set depending on which PTP processing is required.

Reference Timing Source

The MAC supports the following reference timing source features defined in the IEEE 1588-2008 standard:

- 80-bit timestamp
- Fixed Pulse-Per-Second PPS0 Output
- Flexible Pulse-Per-Second PPS0 Output

80-Bit Timestamp

The MAC supports an 80-bit timestamp with a lengthened seconds integer portion which is 48-bits wide. The **Ethernet MAC System Time - Seconds (EMACTIMSEC)** register at offset 0x708 and the **Ethernet MAC System Time-Higher Word Seconds (EMACHWORDSEC)** register at offset 0x724 comprise the seconds count. The 32-bit **Ethernet MAC System Time - Nanoseconds (EMACTIMNANO)** register contains the fractional portion of the timestamp units of nanoseconds. The nanoseconds register supports the following two modes:

- Digital rollover mode: In digital rollover mode, the maximum value in the nanoseconds field is 0x3B9A_C9FF, that is, $(10e9-1)$ nanoseconds.
- Binary rollover mode: In binary rollover mode, the nanoseconds field rolls over and increments the seconds field after value 0x7FFF_FFFF. Accuracy is ~ 0.466 ns per bit.

Digital or binary rollover mode can be selected by programming the `DGTLBIN` bit of the **EMACTIMSTCTRL** register. Note that the timestamp maintained in the MAC is still 64-bits wide, but that the overflow to the upper 16-bits seconds register happens once in 130 years.

Fixed Pulse-Per-Second Output

The Ethernet MAC module supports a pulse-per-second output feature such that the signal, `EN0PPS`, can indicate one second intervals. The frequency of the `EN0PPS` output can be changed by setting the `PPSCTRL` bit field of the **Ethernet MAC PPS Control (EMACPPSCTRL)** register, offset 0x72C.

Flexible Pulse-Per-Second Output

The Ethernet MAC also provides the ability to control the following features of the `EN0PPS` output:

- Start or stop time
- The start point of a single pulse and the start and stop points of the pulse train in terms of a 64-bit system time. The **EMACTIMESEC** and **EMACTIMNANO** registers are used to program the start and stop time.
- The stop time can be programmed in advance of starting.
- The signal width. The rising edge and the corresponding falling edge of the `EN0PPS` output can be programmed in terms of number of units of sub-second increment value programmed in the **Ethernet MAC Sub-Second Increment (EMACSUBSECINC)** register, offset 0x704.
- The signal interval. The time between the rising edges of `EN0PPS` signal, in terms of number of units of sub-second increment value can be programmed in the **Ethernet MAC PPS0 Interval (EMACPPS0INTVL)** register, offset 0x760 . You can program the interval between pulses from 1 to $2^{32}-1$ units of sub-second increment value.
- Cancellation of the programmed `EN0PPS` start or stop request.
- Error indication if the start or stop time being programmed has already passed.

The start time can be programmed in the **EMACTARGSEC** and **EMACTARGNANO** registers. The `TRGTBUSY` bit in the **EMACTARGNANO** register indicates when the value is synchronized to the PTP clock domain. When this bit is clear, a new start time can be programmed, even before the earlier start time has elapsed. The start or stop time should be programmed with advanced system time to ensure proper `EN0PPS` signal output. If the application programs a start or stop time that has already elapsed, then the MAC sets an error status bit indicating the programming error. If enabled, the MAC also sets the Target Time Reached interrupt event. The application can cancel the start or stop request only if the corresponding start or stop time has not elapsed. If the time has elapsed, the cancel command has no effect.

For a flexible `EN0PPS` output, the **EMACPPS0INTVL** and **EMACPPS0WIDTH** registers can be configured. The `PPS0WIDTH` and `PPS0INT` fields are programmed in terms of granularity of system time, that is, number of the units of sub-second increment value. For example, to have a `EN0PPS` pulse width of 80 ns and interval of 120ns, with the PTP reference clock of 25MHz, you should program the width and interval to values 1 and 2, respectively. Note that the `PPS0WIDTH` and `PPS0INT` value must be programmed as one less than the required interval. Before giving the command to trigger a pulse or pulse train on the `EN0PPS` output, the interval and width of the PPS signal output should be programmed or updated.

Advanced Timestamp Transmit Path Functions

The only aspect of the transmit path that changes with advanced timestamp is the descriptor, which extends to 32-bytes long.

When you enable the advanced timestamp feature, the structure of the descriptor changes. The advanced timestamp feature is supported only through the enhanced descriptors format. The descriptor is 32-bytes long (eight words) and the snapshot of the timestamp is written in descriptor TDES6 and TDES7.

Advanced Timestamp Receive Path Functions

When the advanced timestamp feature is enabled, the MAC processes the received frames to identify valid PTP frames. The snapshot of the time sent to the application can be configured to:

- Enable snapshot for all frames
- Enable snapshot for IEEE 1588 version 2 or version 1 timestamp
- Enable snapshot for PTP frames transmitted directly over Ethernet or UDP-IP-Ethernet
- Enable timestamp snapshot for the received frame for IPv4 or IPv6
- Enable timestamp snapshot only for EVENT messages (SYNC, DELAY_REQ, PDELAY_REQ, or PDELAY_RESP)
- Enable the node to be a master or slave and select the snapshot type. This controls the type of messages for which snapshots are taken

The MAC provides the timestamp, along with EOF to the TX/RX Controller. The DMA returns the timestamp inside the corresponding receive descriptor.

24.3.7 Frame Filtering

The following types of filtering are available for receive frames:

- Source Address (SA) or Destination Address (DA) filtering
- VLAN Filtering

The frame filtering supports a sequence where the packet is not forwarded to VLAN filtering if it does not pass the SA or DA filtering first.

24.3.7.1 VLAN Filtering

The Ethernet MAC provides VLAN Tag Perfect Filtering and VLAN Tag Hash Filtering. In VLAN tag perfect filtering, the MAC compares the VLAN tag of the received frame and provides the VLAN frame status to the application. Based on the programmed mode of the `ETV` bit in the **EMACVLANTG** register, the MAC compares the lower 12 bits or all 16 bits of the received VLAN tag to determine the perfect match. If VLAN tag perfect filtering is enabled, the MAC forwards the VLAN-tagged frames along with VLAN tag match status and drops the VLAN frames that do not match. Inverse matching for VLAN frames can also be enabled by setting the `VTIM` bit of the **Ethernet MAC VLAN Tag (EMACVLANTG)** register, offset 0x01C. In addition, matching of S-VLAN tagged frames along with the default C-VLAN tagged frames can be enabled by setting the `ESVL` bit of the **EMACVLANTG** register. The VLAN frame status bit (Bit 10 of `RDES0`) indicates the VLAN tag match status for the matched frames.

Note: The Source or Destination Address filter has precedence over the VLAN tag filters. A frame which fails the Source or Destination Address filter is dropped irrespective of the VLAN tag filter results.

The MAC provides VLAN tag hash filtering with a 16-bit Hash table. The MAC performs the VLAN hash matching based on the V_{THM} bit of the **EMACVLANTG** register. If the V_{THM} bit is set, the most significant four bits of VLAN tag's CRC-32 are used to index the content of the **Ethernet MAC VLAN Hash Table (EMACVLANHASH)** register, offset 0x588. A value of 1 in the **EMACVLANHASH** register, corresponding to the index, indicates that the VLAN tag of the frame matched and the packet should be forwarded. A value of 0 indicates that VLAN-tagged frame should be dropped. The MAC also supports the inverse matching of the VLAN frames. In the inverse matching mode, when the VLAN tag of a frame matches the perfect or hash filter, the packet should be dropped. If the VLAN perfect and VLAN hash match are enabled, a frame is considered as matched if either the VLAN hash or the VLAN perfect filter matches. When inverse match is set, a packet is forwarded only when both perfect and hash filters indicate mismatch. Table 24-19 on page 1635 shows the different possibilities for VLAN matching and the final VLAN match status. When the R_A bit of the **EMACFRAMEFLTR** register is set, all frames are received and the VLAN match status is indicated in Bit 10 of Receive Descriptor word 0 (RDES0). When the R_A bit is not set and the V_{TFE} bit in the **EMACFRAMEFLTR** register is set, the frame is dropped if the final VLAN match status is fail. In Table 24-19 on page 1635, value X means that this column can have any value. When the V_L field is programmed to 0x0 in **EMACVLANTG** register, all VLAN-tagged frames are considered as perfect matched but the status of the VLAN hash match depends on the VLAN hash enable (V_{THM}) bit and VLAN inverse filter (V_{TIM}) bit.

Table 24-19. VLAN Match Status

| VLAN ID (V_L field) | VLAN Perfect Filter Match Status (V_{PF}) | VLAN HASH Enable bit (H_{PF} bit in EMACFRAMEFLTR) | VLAN Hash Filter Match Status (V_{THM}) | VLAN Inverse Filter Bit (V_{TIM}) | Final VLAN Match Status |
|---------------------------|--|---|--|--|----------------------------|
| VL = 0 | Pass | 0 | X | X | Pass |
| | Pass | 1 | X | 0 | Pass |
| | Pass | 1 | Fail | 1 | Pass |
| | Pass | 1 | Pass | 1 | Fail |
| VL !=0 | Pass | X | X | 0 | Pass |
| | Fail | 0 | X | 0 | Fail |
| | Fail | 1 | Fail | 0 | Fail |
| | Fail | 1 | Pass | 0 | Pass |
| | Fail | 0 | X | 1 | Pass |
| | Pass | X | X | 1 | Fail |
| | Fail | 1 | Pass | 1 | Fail |
| Fail | 1 | Fail | 1 | Pass | |

24.3.8 Source Address, VLAN, and CRC Insertion, Replacement or Deletion

The MAC supports the following functions for transmit frames:

- Source Address Insertion or replacement
- VLAN Insertion, Replacement or Deletion
- CRC Replacement

24.3.8.1 Source Address Insertion or Replacement

Software can use the SA insertion or replacement feature to instruct the MAC to do the following for transmit frames:

- Insert the content of the MAC Address Registers in the SA field.
- Replace the content of the SA field with the content of the MAC Address Registers.

The software can enable the SA insertion or replacement for all transmitted frames or selective frames:

- To enable SA insertion or replacement feature for all frames, program the `SADDR` field of the **Ethernet MAC Configuration (EMACCFG)** register.
- To enable SA insertion or replacement for selective frames, program the SA Insertion Control field (TDES1 Bits [31:29]) in the first transmit descriptor of the frame. When Bit 31 of TDES1 is set, the SA Insertion Control field indicates insertion or replacement by MAC Address1 registers. When Bit 31 of TDES1 is reset, it indicates insertion or replacement by MAC Address 0 registers.

When SA insertion is enabled, the application should ensure that the frames that are sent to the MAC do not have the SA field. The MAC does not check the presence of SA field in the transmit frame and just inserts the content of MAC Address Registers in the SA field. Similarly, when SA replacement is enabled, the application should ensure that the frames that are sent to the MAC have the SA field. The MAC just replaces the six bytes, following the Destination Address field in the transmit frame, with the content of the MAC Address Registers.

24.3.8.2 VLAN Insertion, Replacement or Deletion

The software can use the VLAN insertion, replacement, or deletion feature to instruct the MAC to do the following for transmit frames:

- Insert or replace the VLAN Type field (C-VLAN or S-VLAN indicated by the `CSVL` bit of the **Ethernet MAC VLAN Tag Inclusion or Replacement (EMACVLNINCREP)**, MAC offset 0x584) and the VLAN Tag field in the transmit frame with the `VLT` field of the **EMACVLNINCREP** register.
- Delete the VLAN Type and VLAN Tag fields in the transmit frame.

The software can enable the VLAN insertion, replacement, or deletion feature for all transmitted frames or selective frames. To enable this function for all transmit frames, configure the `VLT` field in the **EMACVLNINCREP** register.

When VLAN replacement or deletion is enabled, the MAC checks the presence of the VLAN Type field (0x8100 or 0x88a8), after the Destination address (DA) and SA fields, in the transmit frame. The replace or delete operation does not occur if the VLAN Type field is not detected in the two bytes following the DA and SA fields. However, when VLAN insertion is enabled, the MAC does not check the presence of VLAN Type field in the transmit frame and just inserts the VLAN Type and VLAN Tag fields.

24.3.8.3 CRC Replacement

The software can use the CRC replacement feature to instruct the MAC to replace the FCS field in the transmit frame with the CRC computed by the MAC. This feature works on a per-frame basis. The CRC replacement control field in the Transmit Descriptor Word 0 (TDES0) can be programmed to enable this for a frame. This feature is valid only when the Disable CRC control (Bit 27 of TDES0) is enabled. If SA or VLAN insertion control is enabled, the MAC appends or replaces the FCS field with the computed CRC when Disable CRC Control is enabled or disabled, respectively.

Table 24-20. CRC Replacement Based on Bit 27 and Bit 24 of TDES0

| Bit 27 (DC) | Bit 24 (CRCR) | Description |
|-------------|---------------|--|
| 0 | X | Append CRC When DC= 0, the MAC appends the computed CRC irrespective of the CRCR setting. |
| 1 | 1 | Replace CRC |
| 1 | 0 | No operation (user has appended CRC) |

24.3.9 Checksum Offload Engine

Communication protocols such as TCP and UDP implement checksum fields, which help determine the integrity of data transmitted over a network. Because the most widespread use of Ethernet is to encapsulate TCP and UDP over IP datagrams, the MAC Checksum Offload Engine (COE) supports checksum calculation and insertion in the transmit path, and error detection in the receive path.

24.3.9.1 Transmit Checksum Offload Engine

The checksum for TCP, UDP, or ICMP is calculated over a complete frame, and then inserted into its corresponding header field. Because of this requirement this function is enabled only when the TX FIFO is configured for the store-and-forward mode (the `TSF` bit is set in the `EMACDMAOPMODE` register).

Note: The TX FIFO must be deep enough to store a complete frame before the frame is transferred to the MAC when the checksum offload is being used. If space is not available to accept the programmed burst length of data, the TX/RX Controller starts reading to avoid deadlock. When reading starts, the checksum offload fails and the consequently all succeeding frames may be corrupted because of improper recovery. Therefore, checksum insertion must only be enabled in frames that are less than $[2048 - ((PBL + 3) * 4)]$ bytes in size, where PBL is the Programmable Burst Length field in the `EMACDMABUSMOD` register.

24.3.9.2 IP Header Checksum Engine

In IPv4 datagrams, the integrity of the header fields is indicated by the 16-bit Header Checksum field (the eleventh and twelfth bytes of the IPv4 datagram). The checksum offload engine detects an IPv4 datagram when the Ethernet frame's Type field has the value 0x0800 and the IP datagram's Version field has the value 0x4. The input frame's checksum field is ignored during calculation and replaced with the calculated value. IPv6 headers do not have a checksum field. Therefore, the checksum offload does not modify the IPv6 header fields.

The result of this IP header checksum calculation is indicated by the IP Header Error status bit in the Transmit status (Bit 16 in TDES0). This status bit is set whenever the values of the Ethernet Type field and the IP header's Version field are not consistent, or when the Ethernet frame does not have enough data, as indicated by the IP header Length field. In other words, this bit is set when an IP header error is asserted under the following circumstances:

- For IPv4 datagrams:
 - The received Ethernet type is 0x0800, but the IP header's Version field is not equal to 0x4.
 - The IPv4 Header Length field indicates a value less than 0x5 (20 bytes).
 - The total frame length is less than the value given in the IPv4 Header Length field.
- For IPv6 datagrams:

- The Ethernet type is 0x86dd but the IP header Version field is not equal to 0x6.
- The frame ends before the IPv6 header (40 bytes) or extension header (as given in the corresponding Header Length field in an extension header) is completely received.

If the checksum offload engine detects an IP header error, it still inserts an IPv4 header checksum if the Ethernet Type field indicates an IPv4 payload.

24.3.9.3 Receive Checksum Offload Engine

Both IPv4 and IPv6 frames in the received Ethernet frames are detected and processed for data integrity. The receive checksum feature can be enabled by setting the `IPC` bit of the **Ethernet MAC Configuration (EMACCFG)** register. The EMAC receiver identifies IPv4 or IPv6 frames by checking for value 0x0800 or 0x86DD, respectively, in the received Ethernet frames' Type field. This identification also applies to single VLAN-tagged frames. The offline receive checksum engine calculates IPv4 header checksums and checks that they match the received IPv4 header checksums. The IP Header Error bit is set for any mismatch between the indicated payload type (Ethernet Type field) and the IP header version, or when the received frame does not have enough bytes, as indicated by the Length field of the IPv4 header or when fewer than 20 bytes are available in an IPv4 or IPv6 header. This engine also identifies a TCP, UDP, or ICMP payload in the received IP datagrams (IPv4 or IPv6) and calculates the checksum of such payloads properly, as defined in the TCP, UDP, or ICMP specifications. This engine includes the TCP, UDP, or ICMPv6 pseudo-header bytes for checksum calculation and checks whether the received checksum field matches the calculated value. The result of this operation is given as a Payload Checksum Error bit in the receive status word. This status bit is also set if the length of the TCP, UDP, or ICMP payload does not match the expected payload length given in the IP header.

24.3.10 MAC Management Counters

The MAC Management Counters (MMC) module maintains a set of registers for gathering statistics on the received and transmitted frames. The register set includes a control register for controlling the behavior of the registers, two 32-bit registers containing interrupts generated (one for receive and one for transmit), and two 32-bit registers containing masks for the Interrupt register (one for receive and one for transmit). The MMC counters are free running and start counting when a corresponding frame is received or transmitted. The MMC counter registers provided are as follows:

- **Ethernet MAC Transmit Frame Count for Good and Bad Frames (EMACTXCNTGB)**
- **Ethernet MAC Transmit Frame Count for Frames Transmitted after Single Collision (EMACTXCNTSCOL)**
- **Ethernet MAC Transmit Frame Count for Frames Transmitted after Multiple Collisions (EMACTXCNTMCOL)**
- **Ethernet MAC Transmit Octet Count Good (EMACTXOCTCNTG)**
- **Ethernet MAC Receive Frame Count for Good and Bad Frames (EMACRXCNTGB)**
- **Ethernet MAC Receive Frame Count for CRC Error Frames (EMACRXCNTCRCERR)**
- **Ethernet MAC Receive Frame Count for Alignment Error Frames (EMACRXCNTALGNERR)**
- **Ethernet MAC Receive Frame Count for Good Unicast Frames (EMACRXCNTGUNI)**

24.3.11 Power Management Module

The power management (PMT) module supports the reception of network remote wake-up frames and AMD Magic Packet™ frames. The PMT module does not perform the clock gate function, but generates interrupts for remote wake-up frames and magic packets that the MAC receives.

When the application enables the power-down mode in the PMT module by setting the `PWRDWN` bit in the **Ethernet MAC PMT Control and Status Register (EMACPMTCTLSTAT)** register, MAC offset 0x02C, the MAC drops all received frames and does not forward any frame to the TX/RX Controller Rx FIFO or the application. The MAC comes out of the power-down mode only when a magic packet or a remote wake-up frame is received and the corresponding detection is enabled.

24.3.11.1 Remote Wake-Up

The Remote Wake-Up register bank is made up of eight 32-bit registers. It is loaded by writing the **Ethernet MAC Remote Wake-Up Frame Filter (EMACRWUFF)** register eight times. To load values in the **EMACRWUFF** register, the entire register must be written. The first write is assigned to register 0 of the bank, then register 1 and so on. The **Ethernet MAC Remote Wake-Up Frame Filter (EMACRWUFF)** register is read the same way. The current pointer value of the bank is updated in the Remote Wake-Up FIFO Pointer (`RWKPTR`) field of the **Ethernet MAC PMT Control and Status (EMACPMTCTLSTAT)** register.

Figure 24-13. Wake-Up Frame Filter Register Bank

| | | | | | | | |
|--------------------|------------------|-----------------|------------------|-------------------|------------------|-----------------|------------------|
| Filter 0 Byte Mask | | | | | | | |
| Filter 1 Byte Mask | | | | | | | |
| Filter 2 Byte Mask | | | | | | | |
| Filter 3 Byte Mask | | | | | | | |
| RSVD | Filter 3 Command | RSVD | Filter 2 Command | RSVD | Filter 1 Command | RSVD | Filter 0 Command |
| Filter 3 Offset | | Filter 2 Offset | | Filter 1 Offset | | Filter 0 Offset | |
| Filter 1 CRC - 16 | | | | Filter 0 CRC - 16 | | | |
| Filter 3 CRC - 16 | | | | Filter 2 CRC - 16 | | | |

Filter n Byte Mask

The Filter n Byte Mask registers of the Remote Wake-Up register define the bytes of the frame that are examined by filter n (0, 1, 2, and 3) in order to determine whether or not a frame is a remote wake-up frame. The most significant bit (bit 31) of each mask must be zero. Bits [30:0] are the Byte Mask. If bit, j, of the Byte Mask is set, then the CRC block processes the Filter n Offset + j of the incoming frame; otherwise Filter n Offset + j is ignored.

Filter n Command

The 4-bit Filter n Command field controls the Filter n operation in the following way:

- Filter n Command Bit 3 specifies the address type of the pattern. When the bit is set, the pattern applies to only multicast frames; when the bit is reset, the pattern applies only to unicast frame.
- Filter n Command Bit 2 and Bit 1 are reserved.
- Filter n Command Bit 0 is the enable for Filter n. If bit 0 is not set, filter n is disabled.

Filter n Offset

The Filter n Offset register defines the offset (within the frame) from which the filter n examines the frames. This 8-bit pattern offset is the offset for the filter n first byte to be examined. The minimum allowed offset is 12, which refers to the 13th byte of the frame. The offset value 0 refers to the first byte of the frame.

Filter n CRC-16

The Filter n CRC-16 register contains the CRC_16 value calculated from the pattern and the byte mask programmed to the wake-up filter register block.

24.3.11.2 Remote Wake-Up Frame Detection

When the MAC is in sleep mode and the remote wake-up frame enable bit, `WUPFREN`, is set in the **Ethernet MAC PMT Control and Status (EMACPMTCTLSTAT)** register, the normal operation is resumed after a remote wake-up frame is received. The application writes all eight wake-up filter registers, by performing eight sequential writes to the **Ethernet MAC Remote Wake-Up Frame Filter (EMACRWUFF)** register. The Power Management (PMT) block supports four programmable filters that allow support of different receive frame patterns. If the incoming frame passes the address filtering of Filter Command, and if Filter CRC-16 matches the CRC of the incoming pattern, then the MAC identifies the frame as wake-up frame. The Filter Offset determines the offset from which the frame is to be examined. The Filter Byte Mask determines which bytes of the frame must be examined. The 31st bit of Byte Mask must be set to zero. The remote wake-up CRC block determines the CRC value that is compared with Filter CRC-16. The remote wake-up frame is checked only for length error, FCS error, dribble bit error, MII error, and collision. In addition, the remote wake-up frame is checked to ensure that it is not a runt frame. Even if the remote wakeup frame is more than 512 bytes long, if the frame has a valid CRC value, it is considered valid. The remote wake-up frame detection is updated in the **Ethernet MAC PMT Control and Status (EMACPMTCTLSTAT)** register for every remote wake-up frame received. If the `PMT` interrupt is enabled in the **Ethernet MAC Interrupt Mask (EMACIM)** register, a `PMT` interrupt is asserted and the **EMACPMTCTLSTAT** register can be read to determine reception of a remote wake-up frame.

24.3.11.3 Magic Packet Detection

The magic packet frame is based on a method that uses Advanced Micro Device's magic packet technology to power up the sleeping device on the network. The MAC receives a specific packet of information, called a magic packet, addressed to the node on the network. The MAC checks only those magic packets that are addressed to the MAC or a broadcast address to determine whether these packets meet the wake-up requirements. The magic packets that pass the address filtering (unicast or broadcast) are checked to determine whether they meet the remote wake-up frame data format of 6 bytes of all ones followed by a MAC Address appearing 16 times. The application enables the magic packet wake-up by setting the magic packet enable bit, `MGKPKTEN`, of the **Ethernet MAC PMT Control and Status (EMACPMTCTLSTAT)** register. The power management block constantly monitors each frame addressed to the node for a specific magic packet pattern. Each frame received is checked for a `0xFFFF.FFFF.FFFF` pattern following the destination and source address field. The power management block then checks the frame for 16 repetitions of the MAC address without any breaks or interruptions. In case of a break in the 16 repetitions of the address, the PMT block again

scans the 0xFFFF.FFFF.FFFF pattern in the incoming frame. The 16 repetitions can be anywhere in the frame, but must be preceded by the synchronization stream (0xFFFF.FFFF.FFFF). The device can also accept a multicast frame, as long as the 16 duplications of the MAC address are detected. If the MAC address of a node is 0x0011.2233.4455, then the MAC scans for the following data sequence:

```
Destination Address Source Address ..... FF FF FF FF FF FF
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 ...CRC
```

The magic packet detection is updated in the **EMACPMTCTLSTAT** register for the received magic packet. If the **PMT** interrupt is enabled in the **Ethernet MAC Interrupt Mask (EMACIM)** register, a **PMT** interrupt is asserted and the **EMACPMTCTLSTAT** register can be read to determine whether a magic packet frame has been received.

24.3.11.4 Power Management Interrupts

The **PMT** interrupt signal can be asserted when a valid remote wake-up frame or magic packet is received. The **PMT** interrupt signal restores the application clock and TX clock to the MAC. When the **Ethernet MAC PMT Control and Status (EMACPMTCTLSTAT)** register is read, the **PMT** interrupt is cleared in the **EMACRIS** register at least after four clock cycles of RX clock. When software resets the **PWRDWN** bit in the **Ethernet MAC PMT Control and Status (EMACPMTCTLSTAT)** register, the MAC comes out of the power-down mode, but this event does not generate a **PMT** interrupt.

24.3.11.5 Power-Down/Wake-Up Sequence

The recommended power-down and wake-up sequence is as follows:

1. Disable the Transmit DMA (if applicable) and wait for any previous frame transmissions to complete. These transmissions can be detected when **TI** is set in the **Ethernet MAC DMA Interrupt Status (EMACDMARIS)** register.
2. Disable the MAC transmit and receive state machine by clearing the **TE** and **RE** bits in the **Ethernet MAC Configuration (EMACCFG)** register.
3. Wait until the RX DMA empties all the frames from the Rx FIFO to system memory by polling the **RXF** field of the **Ethernet MAC Status (EMACSTATUS)** register.
4. Enable a power management mode by setting the magic packet, global unicast or remote wake-up enable bit in the **EMACPMTCTLSTAT** register.
5. Enable the MAC receive state machine in the **EMACCFG** register and enter the Power-Down mode by setting the **PWRDWN** bit in the **EMACPMTCTLSTAT** register.
6. On receiving a valid remote wake-up frame, the **PMT** interrupt is set in the **EMACRIS** register and the Ethernet MAC exits the Power-Down mode.
7. Read the **EMACPMTCTLSTAT** register to clear the **PMT** interrupt, then enable the other modules in the system and resume normal operation.

24.3.12 Serial Management Interface

The Ethernet MAC has the ability to read or write to the PHY registers through the EN0MDIO and EN0MDC signals of the Serial Management Interface defined by the IEEE 802.3 standard. The internal EN0MDIO and EN0MDC signals connect to the integrated PHY as well as to the external EN0MDIO and EN0MDC pins. The EN0MDC signal is a 2.5 MHz clock that is sourced from System Clock (SYSCLK) and then divided down to the required frequency by programming the CR field in the **Ethernet MAC MII Address (EMACMIIADDR)** register. To access the integrated PHY, the PLA field in the **EMACMIIADDR** register must be 0x0. The available addresses for external PHYs are 0x01 to 1F.

24.3.13 Reduced Media Independent Interface (RMII)

The Reduced Media Independent Interface (RMII) specification reduces the pin count between Ethernet PHYs and Ethernet MACs. According to the IEEE 802.3u standard, an MII contains 16 pins for data and control. In devices incorporating multiple MAC or PHY interfaces such as switches, the number of pins adds significant cost with increase in port count. The RMII specification addresses this problem by reducing the pin count to 7 for each port — a 62.5% decrease in pin count.

The RMII module has the following features:

- Supports both 10-Mbps and 100-Mbps operating rates
- Provides independent, two-bit wide transmit and receive paths

Each nibble is transmitted on the RMII two bits at a time. For a nibble {D3, D2, D1, D0}, the data is transferred as {D1, D0} followed by {D3, D2}.

24.3.14 Interrupt Configuration

Interrupts can be generated from the MAC as a result of various events in the MAC and sub-modules. MAC interrupts are enabled or disabled in the **Ethernet MAC Interrupt Mask (EMACIM)** register, MAC offset 0x03C. Each interrupt event can be masked by setting the corresponding mask bit in the **EMACIM** register.

The interrupt register bits in the **Ethernet MAC Raw Interrupt Status (EMACRIS)** register only indicate the sub-module from which the event is reported. The application must read the corresponding status registers to clear the interrupt.

24.4 Ethernet PHY

The integrated PHY supports 10Base-T and 100Base-TX signaling. It integrates all the physical-layer functions needed to transmit and receive data on standard twisted-pair cables. The PHY directly interfaces to the integrated Media Access Controller (MAC).

The Ethernet PHY uses mixed-signal processing to perform equalization, data recovery, and error correction to achieve robust operation over CAT5 twisted-pair wiring. It not only meets the requirements of IEEE 802.3, but maintains high margins in terms of alien cross-talk. The following highlights the features of the PHY module:

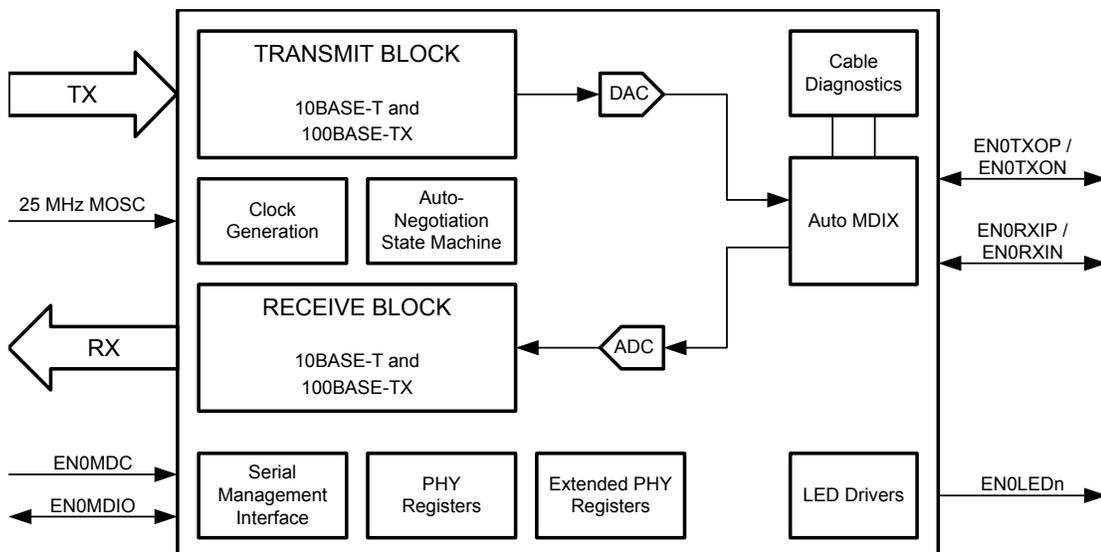

- Cable Diagnostics
- Programmable Fast Link Down Modes
- Auto-MDIX for 10/100Mbps

- Energy Detection Mode
- Serial Management Interface
- IEEE 802.3u Auto-Negotiation and Parallel Detection
- IEEE 802.3u ENDEC, 10Base-T Transceivers and Filters
- IEEE 802.3u PCS, 100Base-TX Transceivers
- Integrated ANSI X3.263 Compliant TP-PMD Physical Sublayer with Adaptive Equalization and Baseline Wander Compensation
- Three programmable LEDs that support detection of Link OK, 10/100Mbs activity, TX/RX transfers, collisions and full duplex mode

24.4.1 Integrated PHY Block Diagram

The following figure shows the internal PHY integration. Note that the reference clock input comes from an external 25 MHz \pm 50 ppm crystal or oscillator connected to the MOSC signals.

Figure 24-14. Integrated PHY Diagram

24.4.2 Functional Description

The following sections describe the functional characteristics of the integrated PHY.

24.4.2.1 Auto-Negotiation

The Ethernet PHY can auto-negotiate to operate in 10Base-T or 100Base-TX. When the Ethernet PHY is enabled or on the deassertion of software reset, the **Ethernet MAC Peripheral Configuration Register (EMACPC)** register, offset 0xFC4, is configured such that auto-negotiation is enabled and the auto negotiation mode ($ANMODE$) bit field is programmed to 10Base-T, Half/Full-Duplex 100Base-TX, Half/Full-Duplex. With auto-negotiation enabled, the PHY negotiates with the link partner to determine the speed and duplex mode with which to operate. If the link partner is unable to auto-negotiate, the PHY goes into parallel-detect mode to determine the speed of the link partner. Under parallel-detect mode, the duplex mode is fixed at half-duplex. The PHY supports four different

Ethernet protocols (10Mbps Half-Duplex, 10Mbps Full-Duplex, 100Mbps Half-Duplex, and 100Mbps Full-Duplex). Auto-Negotiation selects the highest performance protocol based on the advertised ability of the Link Partner. If a different auto-negotiation configuration is required other than the reset initialization values, the application can customize the configuration of the `ANEN` bit and `ANMODE` bit field as described in “Custom Configuration” on page 1653. The values of `ANEN` and `ANMODE` determine whether the PHY is forced into a specific mode, or if Auto-negotiation advertises a specific ability (or abilities) as listed in Table 24-21 on page 1644 and Table 24-22 on page 1644:

Table 24-21. Forced Mode Configurations

| ANEN value | ANMODE | Forced Mode |
|------------|--------|-------------------------|
| 0 | 0x0 | 10Base-T, Half-Duplex |
| 0 | 0x1 | 10Base-T, Full-Duplex |
| 0 | 0x2 | 100Base-TX, Half-Duplex |
| 0 | 0x3 | 100Base-TX, Full-Duplex |

Table 24-22. Advertised Mode Configurations

| ANEN value | ANMODE | Advertised Mode |
|------------|--------|---|
| 1 | 0x0 | 10Base-T, Half/Full-Duplex |
| 1 | 0x1 | 100Base-TX, Half/Full-Duplex |
| 1 | 0x2 | 10Base-T, Half Duplex 100Base-TX, Half Duplex |
| 1 | 0x3 | 10Base-T, Half/Full-Duplex 100Base-TX, Half/Full-Duplex |

24.4.2.2 Auto-MDIX

The PHY automatically determines whether or not it needs to cross over between pairs so that an external crossover cable is not required. If the PHY communicates with a device that implements MDI/MDIX crossover, a random algorithm as described in IEEE 802.3 determines which device performs the crossover. Auto-MDIX is enabled by default at reset. If a different auto-MDIX configuration is required other than the reset initialization, the application can customize the configuration as described in “Custom Configuration” on page 1653. Neither Auto-Negotiation nor Auto-MDIX is required to be enabled in forcing crossover of the MDI pairs. Auto-MDIX can be used in the forced 100Base-TX mode. Because in modern networks all the nodes are 100Base-TX, having the Auto-MDIX working in the forced 100Base-TX mode resolves the link faster without the need for the long Auto-Negotiation period.

24.4.2.3 Isolate Mode

The PHY can be put into Isolate mode by writing `ISOLATE` bit of the **Ethernet PHY Basic Mode Control - MR0 (EPHYBMCR)** register, address 0x000. When in the Isolate mode, the PHY does not respond to packet data present at the internal interface to the Ethernet MAC. When in isolate mode, the PHY continues to respond to all management transactions and the PMD output pair does not transmit packet data, but continues to source 100Base-TX scrambled idles or 10Base-T normal link pulses. The PHY can auto-negotiate or parallel detect on the receive signal at the PMD input pair. A valid link can be established for the receiver even when the PHY is in Isolate mode.

24.4.2.4 LED Interface

The PHY supports three configurable Light Emitting Diode (LED) pins to indicate link status of a port. The **Ethernet PHY LED Configuration - MR37 (EPHYLEDCFG)** register, address 0x025 can be used to assign different functions to each LED. Each LED can be configured to be active during one of these events:

- Link OK (0x0)
- RX/TX Activity (0x1)
- TX Activity (0x2)
- RX Activity (0x3)
- Collision (0x4)
- 100-BASE TX speed (0x5)
- 10-Base TX speed (0x6)
- Full Duplex (0x7)
- Link OK/Blink on TX/RX Activity (0x8)

At reset, LED0 is initialized to display Link OK and LED1 and LED 2 are initialized to the RX/TX activity encoding. The blink rate of the LEDs can be set by programming the `BLINKRATE` bit field of the **Ethernet PHY LED Control - MR24 (EPHYLEDCCR)** register, address 0x018

24.4.2.5 PHY Address

The integrated PHY's address is 0x00. To access the integrated PHY registers through the internal MAC's MDIO interface, the `PLA` bit field of the **Ethernet MAC MII Address (EMACMIIADDR)** register must be 0x00 and the `MII` field should be programmed to the desired address value.

24.4.2.6 Serial Management Interface

The Ethernet MAC module has the capability of programming the integrated PHY registers and extended registers through an internal Serial Management Interface (SMI). The SMI is compatible with IEEE802.3-2002 clause 22.

The SMI includes an MDC management clock input and management MDIO data pin to the Ethernet PHY. The internal MDC clock is sourced by the system clock and then divided down to the required 2.5 MHz maximum clock frequency by setting the `CR` bit in the **Ethernet MAC MII Address (EMACMIIADDR)** register. The MDC is not expected to be continuous, and can be turned off by the external management entity when the bus is idle. The MDIO is sourced by the integrated MAC and by the PHY. The data on the MDIO pin is latched on the rising edge of the MDC clock. The PHY's physical address is 0x00.

24.4.2.7 Extended Address Space Access

The PHY SMI function supports read/write accesses to the extended register set using **Ethernet PHY Register Control - MR13 (EPHYREGCTL)** register and the **Ethernet PHY Address or Data - MR14 (EPHYADDAR)** registers. Accessing the standard register set, MDIO registers 0 to 31, can be performed using the normal direct MDIO access or the indirect method, except for the **EPHYREGCTL (0x00D)** and the **EPHYADDAR (0x00E)** which can be accessed only using the normal MDIO transaction. The SMI function ignores indirect accesses to these registers.

The **EPHYREGCTL** register is the MDIO Manageable MMD access control. In general, register **EPHYREGCTL[4:0]** is the device address `DEVAD` that directs any accesses of **EPHYADDAR** register to the appropriate MMD. Specifically, the PHY uses the vendor specific `DEVAD[4:0] = 0xF` for accesses. All accesses through registers **EPHYREGCTL** and **EPHYADDAR** registers should use

this `DEVAD`. Transactions with other `DEVAD` are ignored. The **EPHYREGCTL[15:14]** register holds the access function:

- **EPHYREGCTL[15:14] = 0x0**: A write to **EPHYADDAR** modifies the extended register set address register. This address register must be initialized in order to access any of the registers within the extended register set.
- **EPHYREGCTL[15:14] = 0x1**: A read/write to **EPHYADDAR** operates on the register within the extended register set selected (pointed to) by the value in the address register. The address register contents (pointer) remain unchanged.
- **EPHYREGCTL[15:14] = 0x2**: A read/write to **EPHYADDAR** operates on the register within the extended register set selected (pointed to) by the value in the address register. After that access is complete, for both reads and writes, the value in the address register is incremented.
- **EPHYREGCTL[15:14] = 0x3**: A read/write to **EPHYADDAR** operates on the register within the extended register set selected (pointed to) by the value in the address register. After that access is complete, for write accesses only, the value in the address register is incremented. For read accesses, the value of the address register remains unchanged.

The following sections describe how to perform operations on the extended register set using the **EPHYREGCTL** and **EPHYADDAR** registers.

Write to PHY Registers

The following describes the steps to write to a PHY register.

1. Check the `MIIB` bit in the **EMACMIADDR** register to identify if the MII interface is busy. When the `MIIB` bit is 0, the MII interface is available to write to the PHY registers.
2. Write the data to be written to the PHY register in the **EMACMIIDATA** register.
3. Initiate write by programming the **EMACMIADDR** register fields as follows:
 - `PLA`: Physical Layer Address of the PHY. The integrated PHY's address is 0x0. The values 0x1 to 0x1F are available for external PHYs.
 - `MII`: Address of the PHY register to be written.
 - `CR`: Clock Reference for the MDIO interface.
 - `MIIW`: Write Initiation. This bit is set to 1 to indicate that a write operation is to be executed.
 - `MIIB`: MII Busy. This bit is set to 1 to indicate that the MII is now busy with a write operation. The EMAC clears this bit when the write has been transmitted.

Write to Extended PHY Registers

The following describes the steps to write to an extended PHY register.

1. Check the `MIIB` bit in the **EMACMIADDR** register to identify if the MII interface is busy. When the `MIIB` bit is 0, the MII interface is available to write to the PHY registers.
2. The **EMACMIIDATA** register should be written with the value to be passed into the **EPHYREGCTL** register. The **EPHYREGCTL** register is used for extended PHY register accesses. The `DEVAD` field of the **EPHYREGCTL** register identifies the device address, which is 0x1F, for

the integrated PHY. The `FUNC` field of the **EPHYREGCTL** register should be set to 0x0 to indicate a write to an extended register address.

3. Initiate write by programming the **EMACMIADDR** register fields as follows:
 - `PLA`: Physical Layer Address of the PHY. The integrated PHY's address is 0x0. The values 0x1 to 0x1F are available for external PHYs.
 - `MII`: Address of the PHY register to be written. In this case, it should be the address of the **EPHYREGCTL** register, 0xD.
 - `CR`: Clock Reference for the MDIO interface.
 - `MIIW`: Write Initiation. This bit is set to 1 to indicate that a write operation is to be executed.
 - `MII B`: MII Busy. This bit is set to 1 to indicate that the MII is now busy with a write operation. The EMAC clears this bit when the write has been transmitted.
4. Check the `MII B` bit in the **EMACMIADDR** register to identify if the MII interface is busy. When the `MII B` bit is 0, the MII interface is available to write to the PHY registers.
5. The **EMACMIIDATA** register should be written with the address of the extended register to be accessed. This value is written to the **EPHYADDR** register.
6. Initiate write by writing the **EMACMIADDR** register fields:
 - `PLA`: Physical Layer Address of the PHY. The integrated PHY's address is 0x0. The values 0x1 to 0x1F are available for external PHYs.
 - `MII`: Address of the PHY register to be written. In this case, it should be the address of the **EPHYADDR** register, 0xE.
 - `CR`: Clock Reference for the MDIO interface.
 - `MIIW`: Write Initiation. This bit is set to 1 to indicate that a write operation is to be executed.
 - `MII B`: MII Busy. This bit is set to 1 to indicate that the MII is now busy with a write operation. The EMAC clears this bit when the write has been transmitted.
7. Check the `MII B` bit in the **EMACMIADDR** register to identify if the MII interface is busy. When the `MII B` bit is 0, the MII interface is available to write to the PHY registers.
8. The **EMACMIIDATA** register should be written with the value to be passed into the **EPHYREGCTL** register. The `DEVAD` field of the **EPHYREGCTL** register identifies the device address, which is 0x1F, for the integrated PHY. The `FUNC` field of the **EPHYREGCTL** register should be set to 0x1 to indicate a write to an extended register address with no increment.
9. Initiate write by writing the **EMACMIADDR** register fields:
 - `PLA`: Physical Layer Address of the PHY. The integrated PHY's address is 0x0. The values 0x1 to 0x1F are available for external PHYs.
 - `MII`: Address of the PHY register to be written. In this case, it should be the address of the **EPHYADDR** register, 0xD.

- CR: Clock Reference for the MDIO interface.
 - MIIW: Write Initiation. This bit is set to 1 to indicate that a write operation is to be executed.
 - MIIB: MII Busy. This bit is set to 1 to indicate that the MII is now busy with a write operation. The EMAC clears this bit when the write has been transmitted.
10. Check the MIIB bit in the **EMACMIADDR** register to identify if the MII interface is busy. When the MIIB bit is 0, the MII interface is available to write to the PHY registers.
 11. The **EMACMIIDATA** register should be programmed with the data to be written to the **EPHYADDR** register which is transferred to the previously selected extended PHY register.
 12. Initiate write by writing the **EMACMIADDR** register fields:
 - PLA: Physical Layer Address of the PHY. The integrated PHY's address is 0x0. The values 0x1 to 0x1F are available for external PHYs.
 - MII: Address of the PHY register to be written. In this case, it should be the address of the **EPHYADDR** register, 0xD.
 - CR: Clock Reference for the MDIO interface.
 - MIIW: Write Initiation. This bit is set to 1 to indicate that a write operation is to be executed.
 - MIIB: MII Busy. This bit is set to 1 to indicate that the MII is now busy with a write operation. The EMAC clears this bit when the write has been transmitted.

Read from PHY Registers

The following describes the steps to read from an extended PHY register.

1. Check the MIIB bit in the **EMACMIADDR** register to identify if the MII interface is busy. When the MIIB bit is 0, the MII interface is available to read to the PHY registers.
2. Initiate the read by writing the **EMACMIADDR** register fields:
 - PLA: Physical Layer Address of the PHY. The integrated PHY's address is 0x0. The values 0x1 to 0x1F are available for external PHYs.
 - MII: Register address of PHY register to be written.
 - CR: Clock Reference for the MDIO interface.
 - MIIW: Write/Read Initiation. This bit is programmed to a 0 to indicate that a read operation is to be executed.
 - MIIB: MII Busy. This bit is set to 1 to indicate that the MII is now busy with a read operation. The EMAC clears this bit when the write has been transmitted.
3. Wait for the MII interface to complete the read by polling the MIIB bit.
4. When the MIIB is clear, read the contents of the **EMACMIIDATA** register.

Read from Extended PHY Registers

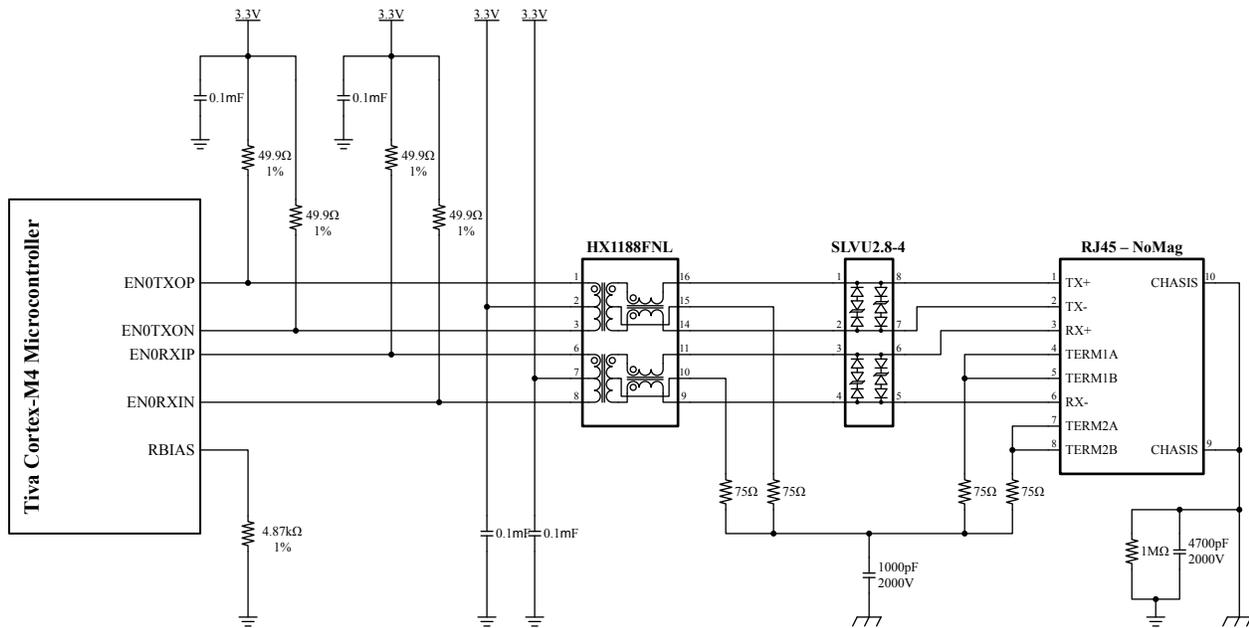

The following describes the steps to read from an extended PHY register.

1. Check the `MIIB` bit in the **EMACMIADDR** register to identify if the MII interface is busy. When the `MIIB` bit is 0, the MII interface is available to read to the PHY registers.
2. Initiate the read by writing the **EMACMIADDR** register fields:
 - `PLA`: Physical Layer Address of the PHY. The integrated PHY's address is 0x0. The values 0x1 to 0x1F are available for external PHYs.
 - `MII`: Register address of PHY register to be written.
 - `CR`: Clock Reference for the MDIO interface.
 - `MIIW`: Write/Read Initiation. This bit is programmed to a 0 to indicate that a read operation is to be executed.
 - `MIIB`: MII Busy. This bit is set to 1 to indicate that the MII is now busy with a read operation. The EMAC clears this bit when the write has been transmitted.
3. Wait for the write to complete by polling the `MIIB` bit.
4. When the `MIIB` is clear, read the contents of the **EMACMIIDATA** register.

24.4.3 Interface Configuration

Figure 24-15 on page 1650 shows the proper method for interfacing the Ethernet Controller to a 10/100BASE-T Ethernet jack.

Figure 24-15. Interface to Ethernet Jack

NOTE: The 0.1mF capacitors on pins 2 and 7 of the HX1188FNL should be located near the physical pins of the transformer.

The Ethernet PHY is designed to work with transformers that meet the IEEE 802.3 standard. To utilize the Auto-MDIX (AMDIX) capability of the Ethernet PHY, a symmetrical transformer is recommended. The Pulse HX1188 transformer has been tested and is known to successfully interface to the Ethernet PHY.

Note: If the PHY is not to be used, then the EN0RXIN/EN0TXON EN0RXIP/EN0TXOP pair should be left unconnected and the RBIAS pin should be unconnected as well.

Note: When entering hibernation in VDD3ON mode, the supply rails to the Ethernet resistors R1, R2, R3, R4 found in Figure 24-15 on page 1650 must be switched off.

24.5 Initialization and Configuration

The MAC module and registers are enabled and powered at reset. When reset has completed, the application should enable the clock to the Ethernet MAC by setting the R0 bit in the **Ethernet Controller Run Mode Clock Gating Control (RCGCEMAC)** register at System Control Module offset 0x69C. When the **PREMAC** register, at System Control offset 0xA9C reads as 0x0000.0001, the EMAC registers are ready to be accessed.

The EMAC interface defaults to MII mode. If RMII mode is required, follow these steps:

1. Enable the external clock source input to the RMII interface signal ENORREF_CLK by setting both the ECEXT and CLKEN bit in the in the **Ethernet Clock Configuration (EMACCC)** register at offset 0xFC8. The external clock source must be 50 MHz with a frequency tolerance of 50 PPM.
2. Select the RMII interface by programming the PINTFS bit field to 0x4 in the **Ethernet Peripheral Configuration (EMACPC)** register at offset 0xFC4.

- Reset the Ethernet MAC to latch the new RMII configuration by setting the `SWR` bit in the **EMACDMABUSMOD** register. This bit resets the Ethernet MAC registers in addition to configuring the RMII interface. Software must poll the `SWR` bit to determine when the new configuration has been registered.

Note: After this configuration is active, if the Ethernet MAC is reset by setting the `R0` bit in the **Ethernet MAC Software Reset (SREMAC)** register in the System Control Module, then the interface is set back to its default MII configuration. In this case, the steps listed above must be repeated to return to an RMII interface.

The Initialization for the DMA for the Ethernet MAC is as follows:

- Write to the Ethernet **MAC DMA Bus Mode (EMACDMABUSMOD)** register to set Host bus parameters.
- Write to the Ethernet **MAC DMA Interrupt Mask Register (EMACDMAIM)** register to mask unnecessary interrupt causes.
- Create the transmit and receive descriptor lists and then write to the **Ethernet MAC Receive Descriptor List Address (EMACRXDLADDR)** register and the **Ethernet MAC Transmit Descriptor List Address (EMACTXLADDR)** register providing the DMA with the starting address of each list.
- Write to the **Ethernet MAC Frame Filter (EMACFRAMEFLTR)** register, the **Ethernet MAC Hash Table High (EMACHASHTBLH)** and the **Ethernet MAC Hash Table Low (EMACHASHTBLL)** for desired filtering options.
- Write to the **Ethernet MAC Configuration Register (EMACCFG)** to configure the operating mode and enable the transmit operation.
- Program Bit 15 (`PS`) and Bit 11 (`DM`) of the **EMACCFG** register based on the line status received or read from the PHY status register after auto-negotiation.
- Write to the **Ethernet MAC DMA Operation Mode (EMACDMAOPMODE)** register to set Bits 13 and 1 to start transmission and reception.
- Write to the **EMACCFG** register to enable the receive operation.

The Transmit and Receive engines enter the Running state and attempt to acquire descriptors from the respective descriptor lists. The Receive and Transmit engines then begin processing Receive and Transmit operations. The Transmit and Receive processes are independent of each other and can be started or stopped separately.

24.5.1 Ethernet PHY Initialization

After reset, when the EMAC is powered and enabled, the **EMACPC** register default reset value may be sampled and used to configure the PHY. The results of this configuration can also be read in the following EPHY registers:

- **EPHYBMCR** register (MR0)
- **EPHYCFG1** register (MR9)
- **EPHYCFG2** register (MR10)
- **EPHYCFG3** register (MR11)

■ EPHYCTL register (MR25)

The mappings of the **EMACPC** register bits to the PHY register and bits are as follows:

Table 24-23. EMACPC to PHY Register Mapping

| EMACPC Register Bit | Corresponding PHY Register | Corresponding PHY Bit (Bit No.) |
|---------------------|----------------------------|---------------------------------|
| PHYEXT | N/A | N/A |
| DIGRESTART | N/A | N/A |
| NIBDETDIS | EPHYCFG2 | ODDNETDIS (1) |
| RXERIDLE | EPHYCFG2 | RXERRIDLE (2) |
| ISOMILL | EPHYCFG2 | ISOMILL (3) |
| LRR | EPHYCFG1 | LLR (7) |
| TDRRUN | EPHYCFG1 | TDRAR (8) |
| FASTLDMODE | EPHYCFG3 | FLDWNM (4:0) |
| POLSWAP | EPHYCFG3 | POLSWAP (7) |
| MDISWAP | EPHYCFG3 | MDIMDIXS (6) |
| RBSTMDIX | EPHYCFG1 | RAMDIX (5) |
| FASTMDIX | EPHYCFG1 | FAMDIX (6) |
| MDIXEN | EPHYCTL | AUTOMDI (15) |
| FASTRXDV | EPHYCFG1 | FRXDVDET (1) |
| FASTLUPD | EPHYCFG2 | FLUPPD (6) |
| EXTFD | EPHYCFG2 | EXTFD (5) |
| FASTANEN | EPHYCFG1 | FASTANEN (4) |
| FASTANSEL | EPHYCFG1 | FANSEL (3:2) |
| ANEN | EPHYBMCR | ANEN |
| ANMODE | N/A | N/A |
| PHYHOLD | N/A | N/A |

The MAC module and registers are enabled and powered at reset. When reset has completed and the clock to the Ethernet MAC is enabled by setting the **R0** bit in the **Ethernet Controller Run Mode Clock Gating Control (RCGCEMAC)** register at System Control Module offset 0x69C, the application has the option to enable the PHY with its default interface configuration (as defined by the **Ethernet MAC Peripheral Configuration Register (EMACPC)** register) or with a custom configuration.

24.5.1.1 Default Configuration

To enable the Ethernet PHY with its default configuration, the steps are as follows:

1. To hold the Ethernet PHY from transmitting energy on the line during configuration, set the **PHYHOLD** bit to 1 in the **EMACPC** register.
2. Enable the clock to the PHY module by writing 0x0000.0001 to the **Ethernet PHY Run Mode Clock Gating Control (RCGCEPHY)** register at offset 0x630. When the **R0** bit reads as 1 in the **PREPHY** register at System Control offset 0xA30, continue initialization.
3. Enable power to the Ethernet PHY by setting the **P0** bit in the **PCEPHY** register at System Control offset 0x930. When the **R0** bit reads as 1 in the **PREPHY** register at System Control offset 0xA30, the PHY registers are ready for programming.

24.5.1.2 Custom Configuration

If a custom configuration of the Ethernet PHY is required, the application can program the configuration registers after reset. The steps for custom configuration are as follows:

1. To hold the PHY from transmitting energy on the line during configuration, set the `PHYHOLD` bit to 1 in the **EMACPC** register.
2. Enable the clock to the PHY module by writing 0x0000.0001 to the **Ethernet PHY Run Mode Clock Gating Control (RCGCEPHY)** register at offset 0x630. When the `R0` bit reads as 1 in the **PREPHY** register at System Control offset 0xA30, continue initialization.
3. Enable power to the Ethernet PHY by setting the `P0` bit in the **PCEPHY** register at System Control offset 0x930. When the `R0` bit reads as 1 in the **PREPHY** register at System Control offset 0xA30, the PHY registers are ready for programming.
4. Once the **Ethernet PHY Peripheral Ready (PREPHY)** register reads 0x0000.0001, software can write the **EMACPC** register with the required value.
5. After software configuration is complete, the application must set the `DONE` bit in the **Ethernet PHY Configuration 1 (EPHYCFG1)** register at offset 0x009.

Note: If a software reset is asserted to the PHY afterwards through the **SREPHY** register, the custom configuration is lost and the steps described above must be repeated.

24.6 Register Map

Table 24-24 on page 1653 lists the Ethernet Controller MAC and PHY registers. For the MAC registers, the offset listed is a hexadecimal increment to the MAC base address of 0x400E.C000. PHY registers are accessed through the **EMACMIIADDR** register thus the base address is n/a (not applicable) and noted as such above the register descriptions.

The *IEEE 802.3* standard specifies a register set for controlling and gathering status from the PHY layer. The registers are collectively known as the MII Management registers. Table 24-24 on page 1653 also lists these MII Management registers for interfacing to the internal PHY. All addresses given are absolute and are written directly to the `MII` field of the **Ethernet MAC MII Address (EMACMIIADDR)** register, offset 0x010. The `PLA` value of the **EMACMIIADDR** register for the internal PHY is 0x00.

The **Ethernet MAC MII Address (EMACMIIADDR)** register, offset 0x010, is used to access MII Management registers on the external PHY device. The `PLA` field in the **EMACMIIADDR** register supports PHY addresses 1 to 31.

Table 24-24. Ethernet Register Map

| Offset | Name | Type | Reset | Description | See page |
|---------------------------------------|---------------|------|-------------|------------------------------|----------|
| Ethernet MAC (Ethernet Offset) | | | | | |
| 0x000 | EMACCFG | RW | 0x0000.8000 | Ethernet MAC Configuration | 1658 |

24.7 Ethernet MAC Register Descriptions

This section lists and describes the MAC registers, in numerical order by address offset. Also see “Ethernet PHY Register Descriptions” on page 1776.

Register 1: Ethernet MAC Configuration (EMACCFG), offset 0x000

The **EMACCFG** register establishes receive and transmit operating modes. Note that the **TWOKPEN** bit is only applicable when the **JFEN** bit is 0.

Ethernet MAC Configuration (EMACCFG)

Base 0x400E.C000

Offset 0x000

Type RW, reset 0x0000.8000

| 31 | reserved | RO | 0x0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. | | | | | | | | | | | | | | |
| 30:28 | SADDR | RW | 0x0 | <p>Source Address Insertion or Replacement Control</p> <p>Bit 30 specifies whether MAC address 0 or 1 registers are used during insertion or replacement for all transmitted frames. Thus for encodings 0x2-0x3, where the most significant bit is 0, the Ethernet MAC Address 0 registers are used.</p> <p>For encodings 0x6-0x7, the Ethernet MAC Address 1 registers are used.</p> <p>Bits [29:28] indicate insertion or replacement. If the value is 0x2 insertion is indicated and if the value is 0x3 replacement is indicated.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0-0x1</td> <td>reserved</td> </tr> <tr> <td>0x2</td> <td>The Ethernet MAC inserts the content of the Ethernet MAC Address 0 (EMACADDR0x) registers in the SA field of all transmitted frames.</td> </tr> <tr> <td>0x3</td> <td>The Ethernet MAC replaces the content of the Ethernet MAC Address 0 (EMACADDR0x) registers in the SA field of all transmitted frames.</td> </tr> <tr> <td>0x4-0x5</td> <td>reserved</td> </tr> <tr> <td>0x6</td> <td>The MAC inserts the content of the Ethernet MAC Address 1 (EMACADDR1x) registers in the source address (SA) field for all transmitted frames.</td> </tr> <tr> <td>0x7</td> <td>The MAC replaces the content of the Ethernet MAC Address 1 (EMACADDR1x) registers in the source address (SA) field for all transmitted frames.</td> </tr> </tbody> </table> <p>Note: Changes in this field take effect only on the start of a frame. If a write of this field occurs while a frame is being transmitted, only the subsequent frame can use the updated value, and the current frame does not.</p> | Value | Description | 0x0-0x1 | reserved | 0x2 | The Ethernet MAC inserts the content of the Ethernet MAC Address 0 (EMACADDR0x) registers in the SA field of all transmitted frames. | 0x3 | The Ethernet MAC replaces the content of the Ethernet MAC Address 0 (EMACADDR0x) registers in the SA field of all transmitted frames. | 0x4-0x5 | reserved | 0x6 | The MAC inserts the content of the Ethernet MAC Address 1 (EMACADDR1x) registers in the source address (SA) field for all transmitted frames. | 0x7 | The MAC replaces the content of the Ethernet MAC Address 1 (EMACADDR1x) registers in the source address (SA) field for all transmitted frames. |
| Value | Description | | | | | | | | | | | | | | | | | |
| 0x0-0x1 | reserved | | | | | | | | | | | | | | | | | |
| 0x2 | The Ethernet MAC inserts the content of the Ethernet MAC Address 0 (EMACADDR0x) registers in the SA field of all transmitted frames. | | | | | | | | | | | | | | | | | |
| 0x3 | The Ethernet MAC replaces the content of the Ethernet MAC Address 0 (EMACADDR0x) registers in the SA field of all transmitted frames. | | | | | | | | | | | | | | | | | |
| 0x4-0x5 | reserved | | | | | | | | | | | | | | | | | |
| 0x6 | The MAC inserts the content of the Ethernet MAC Address 1 (EMACADDR1x) registers in the source address (SA) field for all transmitted frames. | | | | | | | | | | | | | | | | | |
| 0x7 | The MAC replaces the content of the Ethernet MAC Address 1 (EMACADDR1x) registers in the source address (SA) field for all transmitted frames. | | | | | | | | | | | | | | | | | |

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|-------|--|
| 27 | TWOKPEN | RW | 0x0 | <p>IEEE 802.3as Support for 2K Packets</p> <p>When set, the MAC considers all frames, up to 2,000 bytes in length, as normal packets. This bit is only valid when the JFEN bit is set to 0. When JFEN is set, configuring TWOKPEN has no effect on Giant Frame status.</p> <p>Value Description</p> <p>0 If the JFEN bit is clear, the MAC considers all received frames larger than 1,518 bytes (1,522 bytes tagged) as Giant Frames.</p> <p>1 Frames up to 2 KB are considered normal packets. If the JFEN bit is clear, the MAC considers all received frames larger than 2K bytes as Giant frames.</p> |
| 26 | reserved | RO | 0x0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 25 | CST | RW | 0x0 | <p>CRC Stripping for Type Frames</p> <p>When set, the last four bytes (Frame Check Sequence FCS) of all frames of Ether type ((Length/Type field greater than or equal to 0x0600) are removed before forwarding the frame to the application.</p> <p>Value Description</p> <p>0 No bytes are removed.</p> <p>1 The last four bytes are removed before forwarding.</p> |
| 24 | reserved | RO | 0x0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 23 | WDDIS | RW | 0x0 | <p>Watchdog Disable</p> <p>When this bit is set, the MAC disables the internal watchdog counter on the receiver. The MAC can receive frames of up to 16,384 bytes. When this bit is cleared, the MAC does not allow more than 2,048 bytes (10,240 if JFEN is set to 1) of the frame being received. The MAC cuts off any bytes received after 2,048 bytes.</p> <p>Value Description</p> <p>0 Watchdog counter enabled.</p> <p>1 Watchdog counter disabled.</p> |
| 22 | JD | RW | 0x0 | <p>Jabber Disable</p> <p>When this bit is set, the MAC disables the jabber counter on the transmitter. The MAC can transfer frames of up to 16,384 bytes. When this bit is clear, the MAC stops transmission if the application sends out more than 2,048 bytes of data (10,240 if JFEN is set to 1).</p> <p>Value Description</p> <p>0 Jabber counter enabled.</p> <p>1 Jabber counter disabled.</p> |

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|-------|--|
| 21 | reserved | RO | 0x0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 20 | JFEN | RW | 0x0 | <p>Jumbo Frame Enable</p> <p>When this bit is set, the MAC allows jumbo frames of 9,018 bytes (9,022 bytes for VLAN tagged frames) without reporting a giant frame error in the receive frame status.</p> <p>Value Description</p> <p>0 Jumbo frames create giant frame error.</p> <p>1 Jumbo frames allowed without error.</p> |
| 19:17 | IFG | RW | 0x0 | <p>Inter-Frame Gap (IFG)</p> <p>These bits control the minimum IFG between frames during transmission.</p> <p>Value Description</p> <p>0x0 96 bit times</p> <p>0x1 88 bit times</p> <p>0x2 80 bit times</p> <p>0x3 72 bit times</p> <p>0x4 64 bit times</p> <p>0x5 56 bit times</p> <p>0x6 48 bit times</p> <p>0x7 40 bit times</p> <p>In half-duplex mode, the minimum IFG can be configured only for 64 bit times (IFG = 0x4). Lower values are not considered.</p> |
| 16 | DISCRS | RW | 0x0 | <p>Disable Carrier Sense During Transmission</p> <p>When this bit is set, the MAC transmit module ignores carrier sense in half-duplex mode. Thus, errors are not generated when there is a loss of carrier or no carrier during transmission. When this bit is clear, the MAC transmitter generates errors because of carrier sense and can even abort the transmissions.</p> <p>Value Description</p> <p>0 Generate errors for carrier sense errors.</p> <p>1 Ignore carrier sense errors.</p> |
| 15 | PS | RO | 1 | <p>Port Select</p> <p>This bit indicates that a 10/100 Mbps interface is supported on this device. This is a read-only bit.</p> |
| 14 | FES | RW | 0 | <p>Speed</p> <p>This bit indicates the speed of the interface.</p> <p>Value Description</p> <p>0 10 Mbps</p> <p>1 100 Mbps</p> |

| Bit/Field | Name | Type | Reset | Description |
|-----------|--------|------|-------|---|
| 13 | DRO | RW | 0 | <p>Disable Receive Own</p> <p>When this bit is set, the MAC disables the reception of frames while transmitting in half-duplex mode.</p> <p>When this bit is clear, the MAC receives all packets that are given by the PHY while transmitting.</p> <p>Value Description</p> <p>0 All packets are received by MAC.</p> <p>1 Disable reception of frames.</p> <p>Note: This bit is not applicable if the MAC is operating in full-duplex mode.</p> |
| 12 | LOOPBM | RW | 0 | <p>Loopback Mode</p> <p>When this bit is set, the MAC operates in the loopback mode at the MII. The MII Receive clock input, <i>ENORXCK</i>, is required for the loopback to work properly, because the Transmit clock is not looped-back internally.</p> <p>Value Description</p> <p>0 MAC does not operate in loopback mode.</p> <p>1 MAC operates in loopback mode.</p> |
| 11 | DUPM | RW | 0 | <p>Duplex Mode</p> <p>When this bit is set, the MAC operates in the full-duplex mode where it can transmit and receive simultaneously.</p> <p>Value Description</p> <p>0 MAC does not operate in full-duplex mode.</p> <p>1 MAC operates in full-duplex mode.</p> |
| 10 | IPC | RW | 0x0 | <p>Checksum Offload</p> <p>Value Description</p> <p>0 The checksum offload function in the receiver is disabled and the corresponding PCE and IP HCE status bits in the frame status are always cleared.</p> <p>1 Checksum Offload Enable</p> <p>Setting this bit enables the IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking.</p> |

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|-------|--|
| 9 | DR | RW | 0x0 | <p>Disable Retry</p> <p>When this bit is set, the MAC attempts only one transmission. When a collision occurs on the MII interface, the MAC ignores the current frame transmission and reports a frame abort with excessive collision error in the transmit frame status.</p> <p>When this bit is cleared, the MAC attempts retries based on the settings of the BL field (Bits [6:5]).</p> <p>Note: This bit is only applicable in half-duplex mode.</p> <p>Value Description</p> <p>0 MAC retries transmissions based on BL bit field.</p> <p>1 Only one transmission is attempted by the MAC.</p> |
| 8 | reserved | RO | 0x0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 7 | ACS | RW | 0x0 | <p>Automatic Pad or CRC Stripping</p> <p>When this bit is set, the MAC strips the Pad or Frame Check Sequence (FCS) field on the incoming frames only if the value of the length field is less than 1,536 bytes. All received frames with length field greater than or equal to 1,536 bytes are passed to the application without stripping the Pad or FCS field.</p> <p>When this bit is cleared, the MAC passes all incoming frames, without modifying them, to the Host.</p> <p>Value Description</p> <p>0 All frames are passed to host unmodified.</p> <p>1 MAC strips FCS field if value of length field is less than 1,536 bytes.</p> |
| 6:5 | BL | RW | 0x0 | <p>Back-Off Limit</p> <p>The Back-Off limit determines the random integer number (r) of slot time delays (512 bit times for 10/100 Mbps) for which the MAC waits before rescheduling a transmission attempt during retries after a collision. The random integer r takes the value in the range $0 \leq r < 2^k$.</p> <p>The value of k is programmed in the encodings below and is dependent on the retransmission attempt number, n. This bit is applicable only in the half-duplex mode.</p> <p>Value Description</p> <p>0x0 $k = \min(n, 10)$, where k is the lowest value when evaluating n or 10.</p> <p>0x1 $k = \min(n, 8)$, where k is the lowest value when evaluating n or 8.</p> <p>0x2 $k = \min(n, 4)$, where k is the lowest value when evaluating n or 4.</p> <p>0x3 $k = \min(n, 1)$, where k is the lowest value when evaluating n or 1.</p> |

| Bit/Field | Name | Type | Reset | Description |
|-----------|------|------|-------|---|
| 4 | DC | RW | 0x0 | <p>Deferral Check</p> <p>When this bit is set, the deferral check function is enabled in the MAC. When the transmit state machine is deferred for more than 24,288 bit times, the MAC issues a Frame Abort status, and sets the excessive deferral error bit (<i>EXDEFF</i>) in the MAC MMC Transmit Interrupt (EMACMMCTXRIS) Register.</p> <p>If the Jumbo frame mode (<i>JFEN</i>) is enabled, the threshold for deferral is 155,680 bits times. Deferral begins when the transmitter is ready to transmit, but is prevented because of an active carrier sense signal (CRS) on the MII.</p> <p>The defer time is not cumulative. For example, if the transmitter defers for 10,000 bit times because the CRS signal is active and then the CRS signal becomes inactive, the transmitter transmits and collision happens. Because of collision, the transmitter needs to back off and then defer again after back off completion. In such a scenario, the deferral timer is reset to 0 and it is restarted.</p> <p>When this bit is clear, the deferral check function is disabled and the EMAC defers until the CRS signal goes inactive.</p> <p>Note: This bit is only applicable in half-duplex mode.</p> <p>Value Description</p> <p>0 Deferral check function is disabled.</p> <p>1 Deferral check function is enabled.</p> |
| 3 | TE | RW | 0x0 | <p>Transmitter Enable</p> <p>When this bit is set, the transmit state machine of the MAC is enabled for transmission on the MII.</p> <p>When this bit is clear, the MAC transmit state machine is disabled after the completion of the transmission of the current frame, and does not transmit any further frames.</p> <p>Value Description</p> <p>0 MAC transmit state machine is disabled.</p> <p>1 MAC transmit state machine is enabled.</p> |
| 2 | RE | RW | 0x0 | <p>Receiver Enable</p> <p>When this bit is set, the receiver state machine of the MAC is enabled for receiving frames from the MII.</p> <p>When this bit is clear, the MAC receive state machine is disabled after completion of the reception of the current frame, and does not receive any further frames from the MII.</p> <p>Value Description</p> <p>0 MAC receive state machine is disabled.</p> <p>1 MAC receive state machine is enabled.</p> |

| Bit/Field | Name | Type | Reset | Description |
|-----------|--------|------|-------|--|
| 1:0 | PRELEN | RW | 0x0 | <p>Preamble Length for Transmit Frames</p> <p>These bits control the number of preamble bytes that are added to the beginning of every Transmit frame. The preamble reduction occurs only when the MAC is operating in the full-duplex mode.</p> <p>Value Description</p> <p>0x0 7 bytes of preamble</p> <p>0x1 5 bytes of preamble</p> <p>0x2 3 bytes of preamble</p> <p>0x3 reserved</p> |

Register 2: Ethernet MAC Frame Filter (EMACFRAMEFLTR), offset 0x004

The MAC Frame Filter register contains the filter controls for receiving frames. Some of the controls from this register go to the address check block of the MAC, which performs the first level of address filtering. The second level of filtering is performed on the incoming frame, based on other controls such as Pass Bad Frames and Pass Control Frames.

Ethernet MAC Frame Filter (EMACFRAMEFLTR)

Base 0x400E.C000

| 0 | MAC forwards all frames regardless of match status of VLAN Tag. | | | | | | | |
| 1 | MAC drops VLAN tagged frames that do not match VLAN tag comparison. | | | | | | | |
| 15:11 | reserved | RO | 0x0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. | | | | |

| Bit/Field | Name | Type | Reset | Description |
|-----------|------|------|-------|---|
| 10 | HPF | RW | 0 | <p>Hash or Perfect Filter</p> <p>When this bit is set, it configures the address filter to pass a frame if it matches either the perfect filtering or the hash filtering as set by the HMC or HUC bits in this register.</p> <p>When this bit is clear and the HUC or HMC bit is set, the frame is passed only if it matches the Hash filter.</p> <p>Value Description</p> <p>0 Address filter passes a frame if it matches perfect filtering or hash filtering.</p> <p>1 Address filter passes a frame only if it matches in the hash filter.</p> |
| 9 | SAF | RW | 0 | <p>Source Address Filter Enable</p> <p>When this bit is set, the MAC compares the SA field of the received frames with the values programmed in the enabled SA registers. If the comparison matches, then the SA match bit of Receive Status Word is set. When SA Match bit is set and the SA filter fails, the MAC drops the frame.</p> <p>When this bit is clear, the MAC forwards the received frame to the application with the updated SA Match bit of the Receive Status Word depending on the SA address comparison.</p> <p>Value Description</p> <p>0 Source address filter disabled.</p> <p>1 Source address filter enabled.</p> |
| 8 | SAIF | RW | 0 | <p>Source Address (SA) Inverse Filtering</p> <p>When this bit is set, the Address Check block operates in inverse filtering mode for the SA address comparison. The frames whose SA matches the SA registers are marked as failing the SA address filter.</p> <p>When this bit is reset, frames whose SA does not match the SA registers are marked as failing the SA Address filter.</p> <p>Value Description</p> <p>0 Frames whose SA does not match the SA registers are marked as failing.</p> <p>1 Frames whose SA matches the SA registers are marked as failing.</p> |

| Bit/Field | Name | Type | Reset | Description |
|-----------|------|------|-------|--|
| 7:6 | PCF | RW | 0x0 | <p>Pass Control Frames</p> <p>These bits control the forwarding of all control frames (including unicast and multicast PAUSE frames).</p> <p>Value Description</p> <p>0x00 The MAC filters all control frames from reaching application.</p> <p>0x1 MAC forwards all control frames except PAUSE control frames to application even if they fail the address filter.</p> <p>0x2 MAC forwards all control frames to application even if they fail the address Filter.</p> <p>0x3 MAC forwards control frames that pass the address Filter.</p> <p>Note that the following conditions should be true for the PAUSE control frames processing:</p> <ul style="list-style-type: none"> ■ Condition 1: The MAC is in full-duplex mode and flow control is enabled by setting the <code>RFE</code> bit of MAC Flow Control Register (EMACFLOWCTL). ■ Condition 2: The destination address (DA) of the received frame matches the special multicast address or the MAC Address 0 (EMACADDR0x) Register when the <code>UP</code> bit of the (EMACFLOWCTL) is set. ■ Condition 3: The Type field of the received frame is 0x8808 and the <code>OPCODE</code> field is 0x0001. <p>This <code>PCF</code> field should be set to 0x1 only when Condition 1 is true; that is, the MAC is programmed to operate in the full-duplex mode and the <code>RFE</code> bit is enabled. Otherwise, the PAUSE frame filtering may be inconsistent. When Condition 1 is false, the PAUSE frames are considered as generic control frames. Therefore, to pass all control frames (including PAUSE control frames) when the full-duplex mode and flow control is not enabled, you should set the <code>PCF</code> field to 0x2 or 0x3 (as required by the application).</p> |
| 5 | DBF | RW | 0 | <p>Disable Broadcast Frames</p> <p>When this bit is set, the address filtering module (AFM) filters all incoming broadcast frames. In addition, it overrides all other filter settings.</p> <p>Value Description</p> <p>0 Address filtering module passes all received broadcast frames.</p> <p>1 Address filtering module filters all incoming broadcast frames.</p> |
| 4 | PM | RW | 0 | <p>Pass All Multicast</p> <p>When set, this bit indicates that all received frames with a multicast destination address (DA) (first bit in the destination address field is 1) are passed.</p> <p>Value Description</p> <p>0 Filtering of multicast frame depends on <code>HMC</code> bit in this register.</p> <p>1 All received frames with multicast DA are passed.</p> |

| Bit/Field | Name | Type | Reset | Description |
|-----------|------|------|-------|---|
| 3 | DAIF | RW | 0 | <p>Destination Address (DA) Inverse Filtering</p> <p>When this bit is set, the Address Check block operates in inverse filtering mode for the DA address comparison for both unicast and multicast frames.</p> <p>Value Description</p> <p>0 Normal filtering of frames is performed.</p> <p>1 Inverse filtering mode is enabled for DA.</p> |
| 2 | HMC | RW | 0 | <p>Hash Multicast</p> <p>Value Description</p> <p>0 MAC performs a perfect destination address (DA) filtering for multicast frames. It compares the DA field with the values programmed in DA registers.</p> <p>1 MAC performs destination address filtering of received multicast frames according to the hash table.</p> |
| 1 | HUC | RW | 0 | <p>Hash Unicast</p> <p>Value Description</p> <p>0 MAC performs a perfect destination address filtering for unicast frames. It compares the DA field with the values programmed in DA registers.</p> <p>1 MAC performs destination address filtering of unicast frames according to the hash table.</p> |
| 0 | PR | RW | 0x0 | <p>Promiscuous Mode</p> <p>When this bit is set, the Address Filter module passes all incoming frames regardless of its destination or source address. The SA or DA Filter Fails status bits of the Receive Status Word are always cleared when PR is set.</p> <p>Value Description</p> <p>0 Incoming frames are filtered.</p> <p>1 All incoming frames are passed.</p> |

Register 3: Ethernet MAC Hash Table High (EMACHASHTBLH), offset 0x008

The 64-bit Hash table is used for group address filtering. For hash filtering, the contents of the Destination Address (DA) in the incoming frame is passed through the CRC logic, and the upper 6 bits of the CRC register are used to index the contents of the Hash table. The most significant bit determines the register to be used (**Ethernet MAC Hash Table High (EMACHASHTBLH)** or **Ethernet MAC Hash Table Low (MACHASHTBLL)**), and the other five bits determine which bit within the register. A hash value of 5b'00000 selects bit 0 of the selected register, and a value of 5b'11111 selects bit 31 of the selected register.

The hash value of the destination address is calculated in the following way:

1. Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).
2. Perform bit-wise reversal for the value obtained in Step 1.
3. Take the upper 6 bits from the value obtained in Step 2.

For example, if the DA of the incoming frame is received as 0x1F52419CB6AF, then the internally calculated 6-bit Hash value is 0x2C and Bit 12 of **EMACHASHTBLH** register is checked for filtering. If the DA of the incoming frame is received as 0xA00A98000045, then the calculated 6-bit Hash value is 0x07 and Bit 7 of Hash Table Low register is checked for filtering.

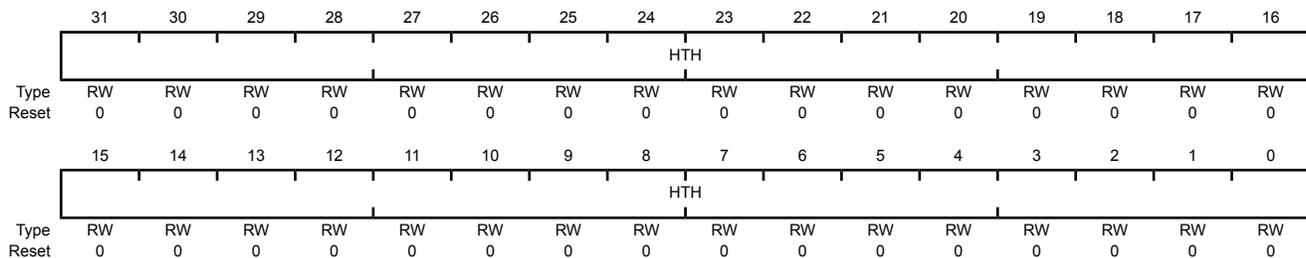

If the corresponding bit value of the register is 0x1, the frame is accepted. Otherwise, it is rejected. If the $\mathcal{P}\mathcal{M}$ (Pass All Multicast) bit is set in the **Ethernet MAC Frame Filter (EMACFRAMEFLTR)** register, then all multicast frames are accepted regardless of the multicast hash values.

Ethernet MAC Hash Table High (EMACHASHTBLH)

Base 0x400E.C000

Offset 0x008

Type RW, reset 0x0000.0000

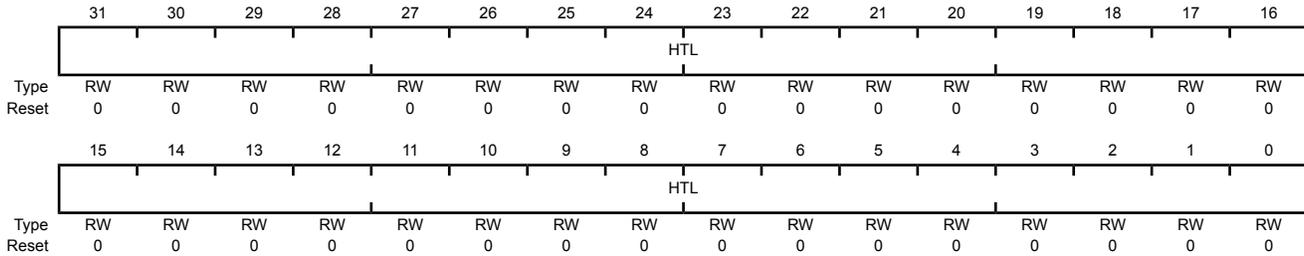

| Bit/Field | Name | Type | Reset | Description |
|-----------|------|------|-------|---|
| 31:0 | HTH | RW | 0x0 | Hash Table High This field contains the upper 32 bits of the hash table. |

Register 4: Ethernet MAC Hash Table Low (EMACHASHTBLL), offset 0x00C

The **MAC Hash Table Low (EMACHASHTBLL)** register contains the lower 32 bits of the hash table.

Register 7: Ethernet MAC Flow Control (EMACFLOWCTL), offset 0x018

The **Ethernet MAC Flow Control (EMACFLOWCTL)** register controls the generation and reception of the control (pause command) frames by the MAC's Flow control module. A write to a register with the **FCBBPA** (bit 0) set to 1 triggers the Flow Control block to generate a pause control frame. The fields of the control frame are selected as specified in the 802.3x specification, and the pause time (**PT**) value from this register is used in the pause time field of the control frame. The **FCBBPA** bit is cleared by the hardware once the control frame is transferred onto the cable. The Host must make sure that the busy bit is clear before writing to the register.

To initiate a Pause control frame, the Application must set this bit to 0x1. During a transfer of the Control Frame, this bit continues to be set to signify that a frame transmission is in progress. After the completion of Pause control frame transmission, the MAC resets this bit to 0x0. The EMACFLOWCTL register should not be written to until this bit is cleared.</p> <p>Value Description</p> <p>0 No effect</p> <p>1 In the full-duplex mode, a pause control frame is enabled. In half-duplex mode, a back-pressure function is enabled if the TFE bit is set.</p> |

Register 8: Ethernet MAC VLAN Tag (EMACVLANTG), offset 0x01C

The **Ethernet MAC VLAN Tag (MACVLANTG)** register contains the IEEE 802.1Q VLAN Tag to identify the VLAN frames. The MAC compares the 13th and 14th bytes of the receiving frame (Length/Type) with the value 0x8100, and the following two bytes are compared with the VLAN tag. If a match occurs, the MAC sets the received VLAN bit in the receive frame status. The legal length of the frame is increased from 1,518 bytes to 1,522 bytes.

Ethernet MAC VLAN Tag (EMACVLANTG)

|-----------|----------|------|-------|---|
| 31:20 | reserved | RO | 0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 19 | VTHM | RW | 0 | VLAN Tag Hash Table Match Enable |
| | | | | Value Description |
| | | | 0 | The VLAN Hash Match operation is not performed. |
| | | | 1 | The most significant four bits of the VLAN tag's CRC are used to index the content of the MAC VLAN Hash Table (EMACVLANTHASH) register. A value of 1 in the EMACVLANTHASH register, corresponding to the index, indicates that the frame matched the VLAN hash table. |
| | | | | When Bit 16 (ETV) is set, the CRC of the 12-bit VLAN Identifier (VID) is used for comparison whereas when ETV is reset, the CRC of the 16-bit VLAN tag is used for comparison. |
| 18 | ESVL | RW | 0 | Enable S-VLAN |
| | | | | Value Description |
| | | | 0 | The MAC transmitter does not recognize S-VLAN frames as valid VLAN tagged frames. |
| | | | 1 | The MAC transmitter and receiver considers the S-VLAN (Type = 0x88A8) frames as valid VLAN tagged frames. |

| Bit/Field | Name | Type | Reset | Description |
|-----------|------|------|--------|--|
| 17 | VTIM | RW | 0 | <p>VLAN Tag Inverse Match Enable</p> <p>Value Description</p> <p>0 VLAN perfect matching is enabled. The frames with matched VLAN tag are marked as matched.</p> <p>1 VLAN tag inverse matching is enabled. The frames that do not have matching VLAN tag are marked as matched.</p> |
| 16 | ETV | RW | 0 | <p>Enable 12-Bit VLAN Tag Comparison</p> <p>Value Description</p> <p>0 All 16 bits of the 15th and 16th bytes of the received VLAN frame are used for comparison and VLAN hash filtering.</p> <p>1 A 12-bit VLAN identifier is used for comparing and filtering instead of the complete 16-bit VLAN tag.</p> <p>Bits [11:0] of VLAN tag are compared with the corresponding field in the received VLAN-tagged frame. Similarly, when enabled, only 12 bits of the VLAN tag in the received frame are used for hash-based VLAN filtering.</p> |
| 15:0 | VL | RW | 0x0000 | <p>VLAN Tag Identifier for Receive Frames</p> <p>This field contains the 802.1Q VLAN tag to identify the VLAN frames and is compared to the 15th and 16th bytes of the frames being received for VLAN frames. The following list describes the bits of this field:</p> <ul style="list-style-type: none"> ■ Bits [15:13]: User Priority ■ Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) ■ Bits[11:0]: VLAN tag's VLAN Identifier (VID) field <p>When the ETV bit is set, only the VID field (Bits[11:0]) is used for comparison. If VL[11:0] is all zeros when the ETV is set, the MAC does not check the fifteenth and 16th bytes for VLAN tag comparison, and declares all frames with a Type field value of 0x8100 or 0x88A8 as VLAN frames.</p> |

Register 9: Ethernet MAC Status (EMACSTATUS), offset 0x024

The **Ethernet MAC Status (EMACSTATUS)** register gives the status of all main modules of the transmit and receive data-paths and the FIFOs. An all-zero status indicates that the MAC is in idle state (and FIFOs are empty) and no activity is going on in the data-paths.

Register 10: Ethernet MAC Remote Wake-Up Frame Filter (EMACRWUFF), offset 0x028

This is the address through which the application writes or reads the remote wake-up frame filter registers. Note that to load values in the **Ethernet MAC Wake-up Frame Filter (EMACRWUFF)** register, the entire register must be written. The **Ethernet MAC Remote Wake-Up Frame Filter (EMACRWUFF)** register is a pointer to eight wake-up frame filter registers. The **Ethernet MAC Remote Wake-Up Frame Filter (EMACRWUFF)** register is loaded by sequentially loading the eight register values. Eight sequential writes to this address programs all of the remote wake-up frame filter registers. Similarly, eight sequential reads from the **EMACRWUFF** register reads all wake-up frame registers.

Register 14: Ethernet MAC Address 0 High (EMACADDR0H), offset 0x040

The **Ethernet MAC Address 0 High (EMACADDR0H)** register holds the upper 16 bits of the first 6-byte MAC address of the station. The first (Destination Address) DA byte that is received on the MII interface corresponds to the least significant byte (Bits [7:0]) of the **MAC Address 0 Low Register (EMACADDR0L)** register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the MII as the destination address, then the **EMAC Address 0 (EMACADDR0x)** register [47:0] is compared with 0x665544332211.

| 0 | CNTRST | RW | 0x0 | Counters Reset Value Description 0 No effect 1 All MMC counters are reset. This bit is cleared automatically after one clock cycle. |

Register 24: Ethernet MAC MMC Receive Raw Interrupt Status (EMACMMCRXRIS), offset 0x104

The **MAC MMC Receive Interrupt (EMACMMCRXRIS)** register maintains the interrupts that are generated when the following happens:

- Receive statistic counters reach half of their maximum values (0x8000.0000 for 32-bit counter and 0x8000 for 16-bit counter).
- Receive statistic counters cross their maximum values (0xFFFF.FFFF for 32-bit counter and 0xFFFF for 16-bit counter).

When the Counter Stop Rollover (CNTSTPRO bit) in the **MAC MMC Control (EMACMMCCTRL)** register is set, interrupts are set but the counter remains at all-ones. The **EMACMMCRXRIS** register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (bits[7:0]) of the respective counter must be read in order to clear the interrupt bit.

Register 36: Ethernet MAC VLAN Tag Inclusion or Replacement (EMACVLNINCREP), offset 0x584

The **MAC VLAN Tag Inclusion or Replacement (EMACVLNINCREP)** register contains the VLAN tag for insertion or replacement in the transmit frames.

Ethernet MAC VLAN Tag Inclusion or Replacement (EMACVLNINCREP)

Base 0x400E.C000
 Offset 0x584
 Type RW, reset 0x0000.0000

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|-------|---|
| 31:20 | reserved | RO | 0x0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 19 | CSVL | RW | 0x0 | C-VLAN or S-VLAN Value Description 0 C-VLAN type (0x8100) is inserted or replaced in the transmitted frames. 1 S-VLAN type (0x88A8) is inserted or replaced in the 13th and 14th bytes of transmitted frames. |
| 18 | VLP | RW | 0x0 | VLAN Priority Control Value Description 0 The control input from the transmit descriptor is used, and the VLC bit field (bits [17:16]) is ignored. 1 The VLC bit field is used for VLAN deletion, insertion, or replacement. |

| Bit/Field | Name | Type | Reset | Description |
|-----------|------|------|-------|---|
| 17:16 | VLC | RW | 0x0 | <p>VLAN Tag Control in Transmit Frames</p> <p>Value Description</p> <p>0x0 No VLAN tag deletion, insertion, or replacement</p> <p>0x1 VLAN tag deletion The MAC removes the VLAN type (bytes 13 and 14) and VLAN tag (bytes 15 and 16) of all transmitted frames with VLAN tags.</p> <p>0x2 VLAN tag insertion The MAC inserts <i>VLT</i> in bytes 15 and 16 of the frame after inserting the Type value (0x8100/0x88a8) in bytes 13 and 14. This operation is performed on all transmitted frames, irrespective of whether they already have a VLAN tag.</p> <p>0x3 VLAN tag replacement The MAC replaces <i>VLT</i> in bytes 15 and 16 of all VLAN-type transmitted frames (Bytes 13 and 14 are 0x8100/0x88a8).</p> <p>Note: Changes to this field take effect only on the start of a frame. If you write this register field when a frame is being transmitted, only the subsequent frame can use the updated value, that is, the current frame does not use the updated value.</p> |
| 15:0 | VLT | RW | 0x0 | <p>VLAN Tag for Transmit Frames</p> <p>This field contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase. Bits[15:13] are the User Priority, Bit 12 is the CFI/DEI, and Bits[11:0] are the VLAN tag's VID field.</p> |

Register 37: Ethernet MAC VLAN Hash Table (EMACVLANTG), offset 0x588

The 16-bit hash table is used for group address filtering based on VLAN tag when the V_{THM} bit of the **EMACVLANTG** register is set. For hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (enabled by ETV in the **EMACVLANTG** register) in the incoming frame is passed through the CRC logic and the upper four bits of the calculated CRC are used to index the contents of the **EMACVLANTG** register. For example, a hash value of 0x8 selects bit 8 of the VLAN Hash table. The hash value of the destination address is calculated in the following way:

1. Calculate the 32-bit CRC for the VLAN tag or ID (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).
2. Perform bitwise reversal for the value obtained in Step 1.
3. Take the upper four bits from the value obtained in Step 2.

If the corresponding bit value of the register is 0x1, the frame is accepted. Otherwise, it is rejected.

| 5 | ADDREGUP | RW | 0x0 | <p>Addend Register Update</p> <p>Value Description</p> <p>0 No effect.</p> <p>1 When set, the content of the Timestamp Addend register is updated in the PTP block for fine correction. This is cleared when the update is completed. This register bit should be zero before setting it.</p> |
| 4 | INTRIG | RW | 0x0 | <p>Timestamp Interrupt Trigger Enable</p> <p>Value Description</p> <p>0 No effect.</p> <p>1 The timestamp interrupt is generated when the System Time becomes greater than the value written in the Ethernet MAC Target Time Seconds/Nanoseconds (EMACTARGSEC/EMACTARGNANO) registers. This bit is reset after the generation of the Timestamp Trigger Interrupt.</p> |
| 3 | TSUPDT | RW | 0x0 | <p>Timestamp Update</p> <p>This bit should be read zero before updating it. This bit is reset when the update is completed in hardware. The Timestamp Higher Word register is not updated.</p> <p>Value Description</p> <p>0 No effect.</p> <p>1 When set, the system time is updated (added or subtracted) with the value specified in EMACTIMSECU (System Time - Seconds Update Register) and EMACTIMNANOU (System Time - Nanoseconds Update Register).</p> |
| 2 | TSINIT | RW | 0x0 | <p>Timestamp Initialize</p> <p>This bit should read zero before updating it.</p> <p>Value Description</p> <p>0x0 This bit is reset when the initialization is complete.</p> <p>0x1 The system time is initialized (overwritten) with the value specified in the Ethernet MAC System Time-Seconds Update (EMACTIMSECU) and the Ethernet MAC System Time-Nanoseconds Update (EMACTIMNANOU) registers.</p> |

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|-------|---|
| 1 | TSFCUPDT | RW | 0x0 | Timestamp Fine or Coarse Update Value Description 0x0 Indicates the system timestamp update should be done using the coarse method. 0x1 Indicates that the system times update should be done using the fine update method. |
| 0 | TSEN | RW | 0x0 | Timestamp Enable The EMACTIMSEC and the EMACTIMNANO registers must be initialized after enabling this mode. On the receive side, the MAC processes 1588 frames only if this bit is set. Value Description 0x0 The timestamp is not added for the transmit and receive frames and the timestamp generator module is also suspended. 0x1 The timestamp is added for the transmit and receive frames |

Register 39: Ethernet MAC Sub-Second Increment (EMACSUBSECINC), offset 0x704

In the Coarse Update mode (enabled by the `TSCFUPDT` bit in the **MAC Timestamp Control (EMACTIMSTCTRL)** register), the value in the **EMACSUBSECINC** register is added to the system time every clock cycle of slave clock reference, MOSC. In the Fine Update mode, the value in this register is added to the system time whenever the Accumulator gets an overflow.

| 31:8 | reserved | RO | 0x0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 7:0 | SSINC | RW | 0x0 | <p>Sub-second Increment Value</p> <p>The value programmed in this field is accumulated every clock cycle (MOSC) with the contents of the sub-second register. For example, when MOSC is 25 MHz (period is 40 ns), <code>SSINC</code> should be programmed with the value 40 (0x28) when the Ethernet MAC System Time - Nanoseconds (EMACTIMNANO) register has an accuracy of 1 ns (<code>DGTLBIN</code> bit is set in EMACTIMSTCTRL). When <code>DGTLBIN</code> bit is clear, the EMACTIMNANO register has a resolution of ~0.465ns. In this case, a value of 86 (0x56), that is derived by 40ns/0.465, should be programmed in the <code>SSINC</code> field.</p> |

Register 40: Ethernet MAC System Time - Seconds (EMACTIMSEC), offset 0x708

The **MAC System Time - Seconds (EMACTIMSEC)** register, along with the **MAC System Time - Nanoseconds (EMACTIMNANO)** register, indicates the current value of the system time maintained by the MAC. Though it is updated on a continuous basis, there is some delay from the actual time because of clock domain transfer latencies.

Ethernet MAC System Time - Seconds (EMACTIMSEC)

Base 0x400E.C000
 Offset 0x708
 Type RO, reset 0x0000.0000

| Bit/Field | Name | Type | Reset | Description |
|-----------|------|------|-------|--|
| 31:0 | TSS | RO | 0x0 | Timestamp Second The value in this field indicates the current value in seconds of the system time maintained by the MAC. |

Register 41: Ethernet MAC System Time - Nanoseconds (EMACTIMNANO), offset 0x70C

The value in this field has the sub-second representation of time, with an accuracy of 0.46 ns. When `DGTLBIN` in the `EMACTIMSTCTRL` register is set, each bit represents 1 ns and the maximum value is `0x3B9A.C9FF`, after which it rolls-over to zero.

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|-------|--|
| 31:7 | reserved | RO | 0x0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 6:5 | TRGMODS0 | RO | 0x0 | Target Time Register Mode for PPS0 Output This field indicates the Target Time registers (EMACTARGSEC and EMACTARGNANO) mode for the EN0PPS output signal: Value Description 0x0 Indicates that the Target Time registers are programmed only for generating the interrupt event. 0x1 Reserved 0x2 Indicates that the Target Time registers are programmed for generating the interrupt event and starting or stopping the generation of the EN0PPS output signal. 0x3 Indicates that the Target Time registers are programmed only for starting or stopping the generation of the EN0PPS output signal. No interrupt is asserted. |
| 4 | PPSEN0 | RO | 0x0 | Flexible PPS Output Mode Enable Value Description 0x0 Bits[3:0] function as PPS output frequency control (PPSCTRL). 0x1 Bits[3:0] function as PPS Command (PPSCMD). |

| Bit/Field | Name | Type | Reset | Description |
|-----------|---------|------|-------|--|
| 3:0 | PPSCTRL | RW | 0x0 | <p>EN0PPS Output Frequency Control (PPSCTRL) or Command Control (PPSCMD)</p> <p>This bit field has two different functions depending on how the PPSSEN0 bit is set. See the values in Table 24-25 on page 1736.</p> <p>If the PPSSEN0 bit is set to 0x0, this field functions as a PPS0 output frequency control (PPSCTRL), which controls the frequency of the output signal, EN0PPS. The default value of this field is 0x0 and the PPS output is one pulse every second.</p> <p>If the PPSSEN0 bit is 0x1, this field functions as a flexible output command control for the EN0PPS signal. Programming the PPSCTRL bit field with a non-zero value instructs the MAC to initiate an event. When the command is transferred or synchronized to the PTP clock domain, these bits are cleared automatically. Software should ensure that these bits are programmed only when they are "all-zeros."</p> <p>Note that in the binary rollover mode, the EN0PPS signal has a duty cycle of 50 percent with these frequencies.</p> <p>In the digital rollover mode, the EN0PPS signal frequency is an average number. The actual clock is of different frequency that gets synchronized every second. For example:</p> <p>When PPSCTRL = 0x1, EN0PPS (1 Hz) has a low period of 537 ms and a high period of 463 ms.</p> <p>When PPSCTRL = 0x2, EN0PPS (2 Hz) is a sequence of:</p> <ul style="list-style-type: none"> ■ One clock of 50 percent duty cycle and 537 ms period ■ Second clock of 463 ms period (268 ms low and 195 ms high) <p>When PPSCTRL = 0x3, EN0PPS (4 Hz) is a sequence of:</p> <ul style="list-style-type: none"> ■ Three clocks of 50 percent duty cycle and 268 ms period ■ Fourth clock of 195 ms period (134 ms low and 61 ms high) <p>This signaling behavior is because of the non-linear toggling of bits in the digital rollover mode in the Ethernet MAC System Time - Nanoseconds (EMACTIMNANO) register.</p> |

Table 24-25. PPSCTRL Bit Field Values

| Value | Description |
|-------|--|
| 0x0 | <p>When the PPSSEN0 bit = 0x0, the EN0PPS signal is 1 pulse of the PTP reference clock. every second.</p> <p>When the PPSSEN0 bit = 0x1, this encoding indicates no command.</p> |
| 0x1 | <p>When the PPSSEN0 bit = 0x0, the binary rollover is 2 Hz, and the digital rollover is 1 Hz.</p> <p>When the PPSSEN0 bit = 0x1, START single pulse. This command generates a single pulse rising at the start point defined in the Ethernet MAC Target Time Second/Nanoseconds (EMACTARGX) registers (MAC offsets 0x71C and 0x720) and a duration defined in the Ethernet MAC PPS0 Width (EMACPPS0WIDTH) register (offset 0x764).</p> |
| 0x2 | <p>When the PPSSEN0 bit = 0x0, the binary rollover is 4 Hz, and the digital rollover is 2 Hz.</p> <p>When the PPSSEN0 bit = 0x1, START pulse train. This command generates the train of pulses rising at the start point defined in the Ethernet MAC Target Time Second/Nanoseconds (EMACTARGX) registers (MAC offsets 0x71C and 0x720) and repeated at an interval defined in the Ethernet MAC PPS0 Width (EMACPPS0WIDTH) register (offset 0x764). By default, the EN0PPS pulse train is free-running unless stopped by STOP pulse train at a time or STOP pulse train immediately command.</p> |
| 0x3 | <p>When the PPSSEN0 bit = 0x0, the binary rollover is 8 Hz, and the digital rollover is 4 Hz,</p> |

Table 24-25. PPCTRL Bit Field Values (continued)

| Value | Description |
|-------|---|
| | When the PPSEN0 bit = 0x1, cancel START. This command cancels the START single pulse and START pulse train commands if the system time has not crossed the programmed start time. |
| 0x4 | When the PPSEN0 bit = 0x0, the binary rollover is 16 Hz, and the digital rollover is 8 Hz. When the PPSEN0 bit = 0x1, STOP pulse train at time. This command stops the train of pulses initiated by the START pulse train command after the time programmed in the Ethernet MAC Target Time Second/Nanoseconds (EMACTARGX) registers (MAC offsets 0x71C and 0x720). |
| 0x5 | When the PPSEN0 bit = 0x0, the binary rollover is 32 Hz, and the digital rollover is 16 Hz. When the PPSEN0 bit = 0x1, STOP pulse train immediately. This command immediately stops the train of pulses initiated by the START pulse train command. |
| 0x6 | When the PPSEN0 bit = 0x0, the binary rollover is 64 Hz, and the digital rollover is 32 Hz. When the PPSEN0 bit = 0x1, cancel STOP pulse train. This command cancels the STOP pulse train at the time command if the programmed stop time has not elapsed. The EN0PPS pulse train becomes free-running on the successful execution of this command. |
| 0x7 | When the PPSEN0 bit = 0x0, the binary rollover is 128 Hz, and the digital rollover is 64 Hz. When the PPSEN0 bit = 0x1, this encoding is reserved. |
| 0x8 | When the PPSEN0 bit = 0x0, the binary rollover is 256 Hz, and the digital rollover is 128 Hz. When the PPSEN0 bit = 0x1, this encoding is reserved. |
| 0x9 | When the PPSEN0 bit = 0x0, the binary rollover is 512 Hz, and the digital rollover is 256 Hz. When the PPSEN0 bit = 0x1, this encoding is reserved. |
| 0xA | When the PPSEN0 bit = 0x0, the binary rollover is 1.024 kHz, and the digital rollover is 512 Hz. When the PPSEN0 bit = 0x1, this encoding is reserved. |
| 0xB | When the PPSEN0 bit = 0x0, the binary rollover is 2.048 kHz, and the digital rollover is 1.024 kHz. When the PPSEN0 bit = 0x1, this encoding is reserved. |
| 0xC | When the PPSEN0 bit = 0x0, the binary rollover is 4.096 kHz, and the digital rollover is 2.048 kHz. When the PPSEN0 bit = 0x1, this encoding is reserved. |
| 0xD | When the PPSEN0 bit = 0x0, the binary rollover is 8.192 kHz, and the digital rollover is 4.096 kHz. When the PPSEN0 bit = 0x1, this encoding is reserved. |
| 0xE | When the PPSEN0 bit = 0x0, the binary rollover is 16.384 kHz, and the digital rollover is 8.092 kHz. When the PPSEN0 bit = 0x1, this encoding is reserved. |
| 0xF | When the PPSEN0 bit = 0x0, the binary rollover is 32.768 KHz, and the digital rollover is 16.384 KHz. When the PPSEN0 bit = 0x1, this encoding is reserved. |

Register 50: Ethernet MAC PPS0 Interval (EMACPPS0INTVL), offset 0x760

The **MAC PPS0 Interval (EMACPPS0INTVL)** register contains the number of units of sub-second increment value between the rising edges of `EN0PPS` signal output.

Note: The PTP reference clock referred to below is MOSC clock in course update mode and in fine correction mode, is the clock tick at which the system time gets updated.

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|-------|---|
| 31 | RIB | RW | 0x0 | Rebuild Burst Value Description 0x0 During a retry, split or loss of bus, the DMA rebuilds the pending beats of any burst transfer with a continuous, uninterrupted burst until the last word, which is a single burst. 0x1 During a retry, split or loss of bus, the DMA rebuilds the pending beats of any burst transfer initiated with a defined fixed burst of 1, 4, 8, or 16. |
| 30:28 | reserved | RO | 0x0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 27 | TXPR | RW | 0 | Transmit Priority Value Description 0x0 The RX DMA has higher priority than the TX DMA during arbitration for the system bus. 0x1 The TX DMA has higher priority than the RX DMA during arbitration for the system bus. |
| 26 | MB | RW | 0 | Mixed Burst Value Description 0x0 Mixed burst is not enabled. 0x1 If the <code>FB</code> bit is 0, the DMA starts all bursts of length more than 16 with a continuous undefined burst. For bursts less than 16, fixed and single bursts are used. |

| Bit/Field | Name | Type | Reset | Description |
|-----------|-------|------|-------|--|
| 25 | AAL | RW | 0 | <p>Address Aligned Beats</p> <p>Value Description</p> <p>0x0 Address aligned transfers are not enabled.</p> <p>0x1 If the <code>FB</code> bit is set, the internal bus interface generates all bursts aligned to the start address least significant bits. If the <code>FB</code> bit is 0, the first burst is not aligned but subsequent bursts are aligned to the address.</p> |
| 24 | 8xPBL | RW | 0 | <p>8 x Programmable Burst Length (PBL) Mode</p> <p>Value Description</p> <p>0x0 8 x PBL mode is inactive.</p> <p>0x1 Bit field <code>RPBL</code> and bit field <code>PBL</code> are multiplied 8 times. Therefore, the DMA transfers the data in bursts of 8, 16, 32, 64, 128, and 256 words.</p> |
| 23 | USP | RW | 0 | <p>Use Separate Programmable Burst Length (PBL)</p> <p>Value Description</p> <p>0x0 The <code>PBL</code> value in bits[13:8] is applicable for both the RX and TX DMA engines.</p> <p>0x1 RX DMA uses the <code>RPBL</code> bit field as its defined programmable burst length and TX DMA uses the <code>PBL</code> bit field as its defined programmable burst length.</p> |
| 22:17 | RPBL | RW | 0x1 | <p>RX DMA Programmable Burst Length (PBL)</p> <p>When the <code>USP</code> bit is 1, this field is used to indicate the maximum number of words to be transferred in one RX DMA transaction. This is the maximum value that is used in a single block read or write.</p> <p>The RX DMA always attempts to burst as specified in the <code>RPBL</code> bit each time it starts a burst transfer on the system bus. The application can program <code>RPBL</code> with values of 1, 2, 4, 8, 16, and 32. Any other value results in undefined behavior. This field is valid and applicable only when <code>USP</code> is set high.</p> |
| 16 | FB | RW | 0 | <p>Fixed Burst</p> <p>This bit defines if burst is used during burst transfer operations.</p> <p>Value Description</p> <p>0x0 The DMA bursts the entire length during burst transfers except for the last word, which is a single transfer.</p> <p>0x1 The DMA uses only single, or fixed bursts incremented by 4, 8, or 16 during normal bus transfers.</p> |

| Bit/Field | Name | Type | Reset | Description |
|-----------|------|------|-------|---|
| 15:14 | PR | RW | 0x0 | <p>Priority Ratio</p> <p>These bits control the priority ratio in the weighted round-robin arbitration between the RX DMA and TX DMA. These bits are valid only when the <code>DA</code> bit in this register is clear. The priority ratio is RX:TX or TX:RX depending on whether the <code>TXPR</code> bit in this register is clear or set.</p> <p>Value Description</p> <p>0x0 The Priority Ratio is 1:1.</p> <p>0x1 The Priority Ratio is 2:1.</p> <p>0x2 The Priority Ratio is 3:1.</p> <p>0x3 The Priority Ratio is 4:1.</p> |
| 13:8 | PBL | RW | 0x1 | <p>Programmable Burst Length</p> <p>These bits indicate the maximum number of beats to be transferred in one DMA transaction.</p> <p>This is the maximum value that is used in a single block read or write. The DMA always attempts to burst as specified in <code>PBL</code> each time it starts a burst transfer on the bus. <code>PBL</code> can be programmed with permissible values of 1, 2, 4, 8, 16, and 32. Any other value results in undefined behavior. When <code>USP</code> is set high, this <code>PBL</code> value is applicable only for TX DMA transactions.</p> <p>If the number of beats to be transferred is more than 32, then perform the following steps:</p> <ol style="list-style-type: none"> 1. Set the <code>8xPBL</code> mode. 2. Set the <code>PBL</code> value. <p>For example, if the maximum number of beats to be transferred is 64, then first set <code>8xPBL</code> to 1 and then set <code>PBL</code> to 0x8.</p> |
| 7 | ATDS | RW | 0x0 | <p>Alternate Descriptor Size</p> <p>Value Description</p> <p>0 Descriptor size reverts back to four words</p> <p>1 Alternate descriptors, each eight words in length, are used.</p> |
| 6:2 | DSL | RW | 0x0 | <p>Descriptor Skip Length</p> <p>This bit specifies the number of words to skip between two unchained descriptors.</p> <p>The address skipping starts from the end of current descriptor to the start of next descriptor. When the <code>DSL</code> value is equal to zero, then the descriptor table is taken as contiguous by the DMA in Ring mode.</p> |

| Bit/Field | Name | Type | Reset | Description |
|-----------|------|------|-------|--|
| 1 | DA | RW | 0x0 | <p>DMA Arbitration Scheme</p> <p>This bit specifies the arbitration scheme between the transmit and receive paths of the DMA channel.</p> <p>Value Description</p> <p>0 Weighted round-robin with RX:TX or TX:RX. The priority between the paths is according to the priority specified in the <code>PR</code> bit field and priority weights specified in the <code>TXPR</code> bit.</p> <p>1 Fixed priority. The transmit path has priority over receive path when the <code>TXPR</code> bit is set. Otherwise, receive path has priority over the transmit path.</p> |
| 0 | SWR | RW | 0x1 | <p>DMA Software Reset</p> <p>The software reset function is driven by this bit.</p> <p>The reset operation is completed only when all resets in all active clock domains are deasserted. It is essential that all the PHY input clocks are present for the software reset completion. The time of the software reset operation depends on the frequency of the slowest active clock.</p> <p>Value Description</p> <p>0 Reset is completed. A value of 0 should be read before reprogramming any MAC registers after a reset</p> <p>1 MAC DMA Controller resets the logic and all internal registers of the MAC. It is cleared automatically after the reset operation has completed in all of the MAC clock domains.</p> |

Register 53: Ethernet MAC Transmit Poll Demand (EMACTXPOLL), offset 0xC04

The **MAC Transmit Poll Demand (EMACTXPOLL)** register enables the TX DMA to check whether or not the DMA owns the current descriptor. The Transmit Poll Demand command is given to wake up the TX DMA if it is in the suspend mode. The TX DMA can go into the SUSPEND mode because of an underflow error in a transmitted frame or the unavailability of descriptors owned by it. This Transmit Poll Demand command can be given at any time and the TX DMA resets this command when it again starts fetching the current descriptor from host memory.

| 31:0 | RPD | WO | 0x0 | <p>Receive Poll Demand</p> <p>When these bits are written with any value, the DMA reads the current descriptor pointed to by MAC Current Host Receive Descriptor (EMACHOSRXDESC) register. If that descriptor is not available (owned by the Host), the reception returns to the SUSPEND state and the RU bit of EMACDMARIS is not asserted. If the descriptor is available, the RX DMA returns to the active state.</p> |

Register 55: Ethernet MAC Receive Descriptor List Address (EMACRXDLADDR), offset 0xC0C

The **Ethernet MAC Receive Descriptor List Address (EMACRXDLADDR)** register points to the start of the Receive Descriptor List. The descriptor lists reside in the host's physical memory space and must be word-aligned. The DMA internally converts it to a 32-bit aligned address by making the two least significant bits zero. Writing to this register is permitted only when the DMA receive transaction has stopped ($SR = 0$ in the **MAC DMA Operation Mode (EMACDMAOPMODE)** register). When stopped, this register must be written with a new descriptor list address before the receive Start command is given. When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the SR bit is set to 0, then the DMA uses the already existing descriptor address.

Ethernet MAC Receive Descriptor List Address (EMACRXDLADDR)

| 1:0 | reserved | RO | 0x0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |

Register 56: Ethernet MAC Transmit Descriptor List Address (EMACTXDLADDR), offset 0xC10

The **MAC Transmit Descriptor List Address (EMACTXDLADDR)** register points to the start of the transmit descriptor list. The descriptor lists reside in the host's physical memory space and must be word-aligned.

This register can only be written when the DMA transmit has stopped ($ST = 0$ in the **MAC DMA Operation Mode (EMACDMAOPMODE)** register). When the ST bit is set, the DMA takes the uses the newly programmed descriptor base address.

If this register is not changed when the ST bit is set to 0, then the DMA uses the already existing descriptor address.

Register 57: Ethernet MAC DMA Interrupt Status (EMACDMARIS), offset 0xC14

The **MAC DMA Interrupt Status (EMACDMARIS)** register contains all status bits that the DMA reports to the host. The software driver reads this register during an interrupt service routine or polling. Most of the fields in this register cause the host to be interrupted. The bits of this register are not cleared when read. Writing a 1 to any bit in the lower half-word of this register clears the bit and writing a 0 has no effect. Status bits [16:0] can be masked by enabling the appropriate mask in the **MAC DMA Interrupt Mask Register (EMACDMAIM)** register.

| Bit/Field | Name | Type | Reset | Description |
|-----------|------|------|-------|--|
| 6 | FUF | RW | 0x0 | <p>Forward Undersized Good Frames</p> <p>Value Description</p> <p>0 The Receive FIFO drops all frames of less than 64 bytes, unless a frame is already transferred because of the lower value of Receive Threshold (RTC) bit field (for example, RTC = 0x1).</p> <p>1 The Receive FIFO forwards undersized frames (frames with no Error and length less than 64 bytes) including pad-bytes and CRC.</p> |
| 5 | DGF | RW | 0x0 | <p>Drop Giant Frame Enable</p> <p>Value Description</p> <p>0 The MAC does not drop the giant frames in the RX FIFO.</p> <p>1 The MAC drops received frames larger than the computed giant frame limit in the RX FIFO.</p> |
| 4:3 | RTC | RW | 0x0 | <p>Receive Threshold Control</p> <p>These two bits control the threshold level of the RX FIFO. Transfer (request) to DMA starts when the frame size within the RX FIFO is larger than the threshold. In addition, full frames with length less than the threshold are transferred automatically.</p> <p>These bits are valid only when the RSF bit (bit 25) of the EMACDMAOPMODE is zero, and are ignored when the RSF bit is set to 1.</p> <p>Value Description</p> <p>0x0 64 bytes</p> <p>0x1 32 bytes</p> <p>0x2 96 bytes</p> <p>0x3 128 bytes</p> |
| 2 | OSF | RW | 0x0 | <p>Operate on Second Frame</p> <p>Value Description</p> <p>0 DMA processes frames normally.</p> <p>1 DMA processes second frame of the Transmit data even before the status for the first frame is obtained.</p> |

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|-------|--|
| 1 | SR | RW | 0x0 | <p>Start or Stop Receive</p> <p>When this bit is set, the Receive process is placed in the Running state. The DMA attempts to acquire the descriptor from the Receive list and processes the incoming frames. The descriptor acquisition is attempted from the current position in the list, which is the address set by the Receive Descriptor List Address Register (EMACRXDLADDR) or the position retained when the Receive process was previously stopped. If the DMA does not own the descriptor, reception is suspended and Bit 7 (Receive Buffer Unavailable, RU) of the MAC DMA Interrupt Status Register (EMACDMARIS) is set. The Start Receive command is effective only when the reception has stopped. If the command is issued before setting EMACRXDLADDR, the DMA behavior is unpredictable.</p> <p>When this bit is cleared, the receive DMA operation is stopped after the transfer of the current frame. The next descriptor position in the Receive list is saved and becomes the current position after the Receive process is restarted. The Stop Receive command is effective only when the Receive process is in either the Running (waiting for receive packet) or in the Suspended state.</p> <p>Value Description</p> <p>0 The receive DMA operation is stopped after the transfer of the current frame</p> <p>1 The Receive process is placed in the Running state.</p> |
| 0 | reserved | RO | 0x0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |

Register 59: Ethernet MAC DMA Interrupt Mask Register (EMACDMAIM), offset 0xC1C

The Interrupt Enable register enables the interrupts reported by the MAC DMA Interrupt Status Register (**EMACDMARIS**). Setting a bit to 0x1 enables a corresponding interrupt. After a hardware or software reset, all interrupts are disabled.

Ethernet MAC DMA Interrupt Mask Register (EMACDMAIM)

Register 60: Ethernet MAC Missed Frame and Buffer Overflow Counter (EMACMFBOC), offset 0xC20

The DMA maintains two counters to track the number of frames missed during reception. This register reports the current value of the counters. The counter is used for diagnostic purposes. The MISFRMCNT field indicates missed frames because of the host buffer being unavailable. The OVFFRMCNT field indicates missed frames because of buffer overflow conditions (MTL and MAC) and runt frames (good frames of less than 64 bytes) dropped by the MTL.

Ethernet MAC Missed Frame and Buffer Overflow Counter (EMACMFBOC)

| 25 | DIGRESTART | RW | 0 | <p>PHY Soft Restart</p> <p>This bit allows the user to restart the PHY. Asserting this bit causes the PHY logic and internal register to reset to initial conditions. This bit does not affect the configuration bits provided by the EMACPC register, which are stored in the PHY following a chip reset. To initiate the soft reset to the PHY, this bit must be written to a 1 and written again to a 0.</p> | | | | | | | | | | |

| Bit/Field | Name | Type | Reset | Description |
|-----------|------------|------|-------|--|
| 24 | NIBDETDIS | RO | 0 | Odd Nibble TXER Detection Disable This bit is sampled on the deassertion of the PHY reset signal and is used as the default for the <code>ODDNDETDIS</code> bit of the Ethernet PHY Configuration 2 (EPHYCFG2) register, PHY offset 0x00A. |
| 23 | RXERIDLE | RW | 1 | RXER Detection During Idle This bit is sampled on the deassertion of the PHY reset signal and is used as the default for the <code>RXERRIDLE</code> bit of the Ethernet PHY Configuration 2 (EPHYCFG2) register, PHY offset 0x00A. |
| 22 | ISOMIILL | RW | 0 | Isolate MII in Link Loss This bit is sampled on the deassertion of the PHY reset signal and is used as the default for the <code>ISOMIILL</code> bit of the Ethernet PHY Configuration 2 (EPHYCFG2) register, PHY offset 0x00A. |
| 21 | LRR | RW | 0 | Link Loss Recovery This bit is sampled on the deassertion of the PHY reset signal and is used as the default for the <code>LLR</code> bit of the Ethernet PHY Configuration 1 (EPHYCFG1) register, PHY offset 0x009. |
| 20 | TDRRUN | RW | 0 | TDR Auto Run This bit is sampled on the deassertion of the PHY reset signal and is used as the default for the <code>TDRAR</code> bit of the Ethernet PHY Configuration 1 (EPHYCFG1) register, PHY offset 0x009. |
| 19:15 | FASTLDMODE | RW | 0 | Fast Link Down Mode These bits are sampled on the deassertion of the PHY reset signal and are used as the default for the <code>FLDWNM</code> bit field of the Ethernet PHY Configuration 3 (EPHYCFG3) register, PHY offset 0x00B. |
| 14 | POLSWAP | RW | 0 | Polarity Swap This bit is sampled on the deassertion of the PHY reset signal and is used as the default for the <code>POLSWAP</code> bit of the Ethernet PHY Configuration 3 (EPHYCFG3) register PHY offset 0x00B. |
| 13 | MDISWAP | RW | 0 | MDI Swap This bit is sampled on the deassertion of the PHY reset signal and is used as the default for the <code>MDIMDIXS</code> bit of the Ethernet PHY Configuration 3 (EPHYCFG3) register, PHY offset 0x00B. |
| 12 | RBSTMDIX | RW | 0 | Robust Auto MDI-X This bit is sampled on the deassertion of the PHY reset signal and is used as the default for the <code>RAMDIX</code> bit of the Ethernet PHY Configuration 1 (EPHYCFG1) register, PHY offset 0x009. |
| 11 | FASTMDIX | RO | 0 | Fast Auto MDI-X This bit is sampled on the deassertion of the PHY reset signal and is used as the default for the <code>FAMDIX</code> bit of the Ethernet PHY Configuration 1 (EPHYCFG1) register, PHY offset 0x009. |

| Bit/Field | Name | Type | Reset | Description |
|-----------|-----------|------|-------|---|
| 10 | MDIXEN | RW | 1 | <p>MDIX Enable</p> <p>This bit is sampled on the deassertion of the PHY reset signal and is used to determine whether automatic MDI/MDIX crossover is enabled.</p> <p>Value Description</p> <p>0 Disable automatic cross-over.</p> <p>1 Enable automatic cross-over.</p> |
| 9 | FASTRXDV | RW | 0 | <p>Fast RXDV Detection</p> <p>This bit is sampled on the deassertion of the PHY reset signal and is used to select whether fast RXDV detection is enabled in the PHY.</p> <p>Value Description</p> <p>0 Disable fast RXDV detection.</p> <p>1 Enable fast RXDV detection.</p> |
| 8 | FASTLUPD | RW | 0 | <p>FAST Link-Up in Parallel Detect</p> <p>This bit is sampled on the deassertion of the PHY reset signal and is used as the default value for the <code>FLUPPD</code> bit of the Ethernet PHY Configuration 2 (EPHYCFG2) register, PHY offset 0x00A.</p> |
| 7 | EXTFD | RW | 0 | <p>Extended Full Duplex Ability</p> <p>This bit is sampled on the deassertion of the PHY reset signal and is used as the default value for the <code>EXTFD</code> bit of the Ethernet PHY Configuration 2 (EPHYCFG2) register, PHY offset 0x00A.</p> |
| 6 | FASTANEN | RW | 0 | <p>Fast Auto Negotiation Enable</p> <p>This bit is sampled on the deassertion of the PHY reset signal and is used as the default for the <code>FASTANEN</code> bit of the Ethernet PHY Configuration 1 (EPHYCFG1) register, PHY offset 0x009.</p> |
| 5:4 | FASTANSEL | RW | 0 | <p>Fast Auto Negotiation Select</p> <p>These bits are sampled on the deassertion of the PHY reset signal and are used as the defaults for the <code>FANSEL</code> bit field of the Ethernet PHY Configuration 1 (EPHYCFG1) register, PHY offset 0x009.</p> |
| 3 | ANEN | RW | 1 | <p>Auto Negotiation Enable</p> <p>This bit is sampled on the deassertion of the PHY reset signal and is to select whether auto-negotiation is enabled.</p> <p>Value Description</p> <p>0 Auto-negotiation disabled.</p> <p>1 Auto-negotiation enabled.</p> |

| Bit/Field | Name | Type | Reset | Description |
|-----------|---------|------|-------|--|
| 2:1 | ANMODE | RW | 3 | <p>Auto Negotiation Mode</p> <p>These bits are sampled on the deassertion of the PHY reset signal and are used to determine the auto-negotiation mode of the PHY.</p> <p>Value Description</p> <p>0x0 When ANEN = 0x0, the mode is 10Base-T, Half-Duplex When ANEN=0x1, the mode is 10Base-T, Half/Full-Duplex</p> <p>0x1 When ANEN = 0x0, the mode is 10Base-T, Full-Duplex When ANEN=0x1, the mode is 100Base-TX, Half/Full-Duplex</p> <p>0x2 When ANEN = 0x0, the mode is 100Base-TX, Half-Duplex When ANEN=0x1, the mode is 10Base-T,Half-Duplex 100Base-TX, Half-Duplex</p> <p>0x3 When ANEN = 0x0, the mode is 100Base-TX, Full-Duplex When ANEN=0x1, the mode is 10Base-T,Half/Full-Duplex 100Base-TX, Half/Full-Duplex</p> |
| 0 | PHYHOLD | RW | 0 | <p>Ethernet PHY Hold</p> <p>This bit is sampled on the deassertion of the PHY reset signal and is used to keep the PHY from transmitting energy on the line.</p> <p>Value Description</p> <p>0 PHY transmits energy on the line.</p> <p>1 PHY is held off from transmitting energy on the line.</p> |

Register 68: Ethernet MAC Clock Configuration Register (EMACCC), offset 0xFC8

The following register is used to configure the clocks of the Ethernet Controller.

Ethernet MAC Clock Configuration Register (EMACCC)

|-----------|----------|------|-------|---|
| 31:1 | reserved | RO | 0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 0 | INT | RW | 0 | Ethernet PHY Interrupt Mask |

Value Description

- | | |
|---|--|
| 0 | An Ethernet PHY interrupt is suppressed and not sent to the interrupt controller. |
| 1 | An Ethernet PHY interrupt is sent to the interrupt controller when the <code>INT</code> bit is set in the EPHYRIS register. This interrupt could be generated from either the integrated PHY or an external PHY through the <code>EN0INTR</code> signal depending on the configuration chosen. |

Register 71: Ethernet PHY Masked Interrupt Status and Clear (EPHYMISC), offset 0xFD8

The **Ethernet Masked Interrupt Status and Clear (EPHYMISC)** register displays the masked interrupt status of the Ethernet PHY, which is either from the internal integrated PHY or an external PHY. This register can be written to clear the **EPHYRIS** register.

This register is used for clearing the **EPHYRIS** register bits.

Ethernet PHY Masked Interrupt Status and Clear (EPHYMISC)

Base 0x400E.C000
Offset 0xFD8
Type RW1C, reset 0x0000.0000

Register 74: Ethernet PHY Identifier Register 1 - MR2 (EPHYID1), address 0x002

The **Ethernet PHY Identifier 1 and 2 (EPHYIDn)** registers together form a unique identifier. The identifier consists of a concatenation of the Organizationally Unique Identifier (OUI), the vendor's model number and the model revision number. A PHY may return a value of zero in each of the 32 bits of the PHY Identifier if desired. The PHY Identifier is intended to support network management. The Texas Instruments IEEE-assigned OUI is 0x080028. This OUI field is broken into two fields in the **EPHYID1** and **EPHYID2** register. The most significant OUI field, **OUI_MSB** in the **EPHYID1** register, is equal to 0x0002 (the two most significant bits of the OUI are ignored). The least significant OUI field, **OUI_LSB** in the **EPHYID2** register, is equal to 0x28.

Ethernet PHY Identifier Register 1 - MR2 (EPHYID1)

The application can enable combinations of these conditions.</p> <p>Bit 4: Drop the link due to descrambler sync loss. If this bit is enabled, the link is dropped when the receiver loses synchronization of the transmitter.</p> <p>Bit 3: Drop the link based on RX Error count of the MII interface. When a predefined number of 32 RX Error occurrences in a 10µs interval is reached, the link is dropped.</p> <p>Bit 2: Drop the link based on MLT3 Errors count (Violation of the MLT3 coding in the DSP output). When a predefined number of 20 MLT3 Error occurrences in a 10µs interval is reached, the link is dropped.</p> <p>Bit 1: Drop the link based on Low SNR Threshold. When a predefined number of 20 Threshold crossing occurrences in a 10µs interval is reached, the link is dropped.</p> <p>Bit 0: Drop the link based on Signal/Energy loss indication – When the Energy detector indicates Energy Loss, the link is dropped. Typical reaction time is 10µs.</p> |

Register 84: Ethernet PHY Register Control - MR13 (EPHYREGCTL), address 0x00D

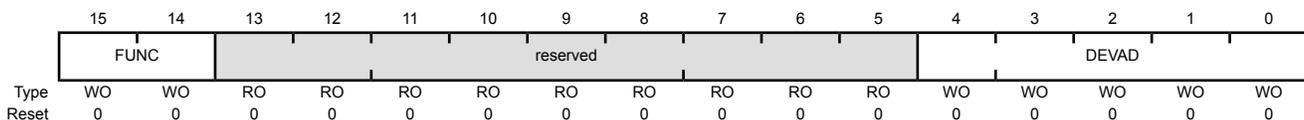

EPHYREGCTL (0x00D) and **EPHYADDAR** (0x00E) registers allow read/write access to the extended register set using indirect addressing. The modes for the **FUNC** field are as follows:

- **EPHYREGCTL[15:14] = 0x0**: A write to **EPHYADDAR** modifies the extended register set address register. This address register must be initialized in order to access any of the registers within the extended register set.
- **EPHYREGCTL[15:14] = 0x1**: A read/write to **EPHYADDAR** operates on the register within the extended register set selected (pointed to) by the value in the address register. The address register contents (pointer) remain unchanged.
- **EPHYREGCTL[15:14] = 0x2**: A read/write to **EPHYADDAR** operates on the register within the extended register set selected (pointed to) by the value in the address register. After that access is complete, for both reads and writes, the value in the address register is incremented.
- **EPHYREGCTL[15:14] = 0x3**: A read/write to **EPHYADDAR** operates on the register within the extended register set selected (pointed to) by the value in the address register. After that access is complete, for write accesses only, the value in the address register is incremented. For read accesses, the value of the address register remains unchanged.

This register is the MDIO Manageable Device (MMD) access control. In general, register **EPHYREGCTL [4:0]** is the device address, **DEVAD**, that directs any accesses of **EPHYADDAR** (0x00E) register to the appropriate MMD. It also contains selection bits for auto-increment of the data register. This register contains the device address to be written to access the extended registers. Write 0x1F into bits [4:0] of this register. It also contains selection bits [15:14] for the address auto-increment mode of **EPHYADDAR**.

Ethernet PHY Register Control - MR13 (EPHYREGCTL)

Base n/a
Address 0x00D
Type WO, reset 0x0000

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|-------|---|
| 15:14 | FUNC | WO | 0 | Function Value Description 0x0 Address 0x1 Data, no post increment 0x2 Data, post increment on read and write 0x3 Data, post increment on write only |
| 13:5 | reserved | RO | 0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |

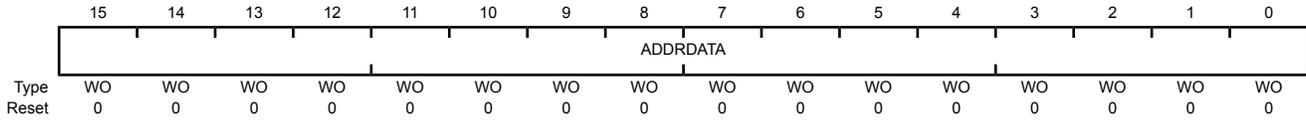

| Bit/Field | Name | Type | Reset | Description |
|-----------|-------|------|-------|--|
| 4:0 | DEVAD | WO | 0x0 | Device Address In general, these bits [4:0] are the device address <code>DEVAD</code> that directs any accesses of <code>EPHYADDR</code> register (0x00E) to the appropriate MMD. The PHY uses the vendor specific <code>DEVAD [4:0] = 0x1F</code> for accesses. All accesses through registers <code>EPHYREGCR</code> and <code>EPHYADDR</code> should use this <code>DEVAD</code> . Transactions with other <code>DEVAD</code> are ignored. |

Register 85: Ethernet PHY Address or Data - MR14 (EPHYADDR), address 0x00E

This register is the address/data MMD register. It is used in conjunction with **EPHYREGCTL** register (PHY offset 0x00D) to provide the access by an indirect read/write mechanism to the extended register set.

Ethernet PHY Address or Data - MR14 (EPHYADDR)

Base n/a
 Address 0x00E
 Type WO, reset 0x0000

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|--------|---|
| 15:0 | ADDRDATA | WO | 0x0000 | Address or Data If the EPHYREGCTL register bits [15:14] = 0x0, this register holds the MDIO Manageable Device (MMD) DEVAD's address register, otherwise holds the MMD DEVAD's data register. See EPHYREGCTL register for more information about DEVAD field. |

Register 86: Ethernet PHY Status - MR16 (EPHYSTS), address 0x010

This register provides quick access to commonly accessed PHY control status and general information.

Ethernet PHY Status - MR16 (EPHYSTS)

Base n/a

Address 0x010

Type RO, reset 0x0002

Register 88: Ethernet PHY MII Interrupt Status 1 - MR18 (EPHYMISR1), address 0x012

This register contains events status and enables for the interrupt function. If an event has occurred since the last read of this register, the corresponding status bit is set. If the corresponding enable bit in the register is set, an interrupt is generated if the event occurs. The `INTEN` bit (Bit 1) in the `EPHYSCR` register (0x011) must also be set to allow interrupts. The status indications in this register are set even if the interrupt is not enabled.

Register 89: Ethernet PHY MII Interrupt Status 2 - MR19 (EPHYMISR2), address 0x013

This register contains additional event status and enables for the interrupt function. If an event has occurred since the last read of this register, the corresponding status bit is set. If the corresponding enable bit in the register is set, an interrupt is generated if the event occurs. The `INTEN` bit (bit 1) in the `EPHYSCR` register (PHY offset 0x011) must also be set to allow interrupts. The status indications in this register are set even if the interrupt is not enabled.

Register 90: Ethernet PHY False Carrier Sense Counter - MR20 (EPHYFCSCR), address 0x014

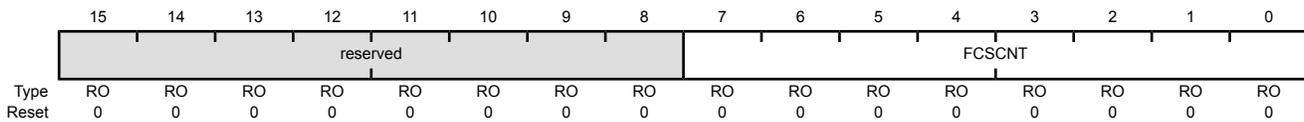

This counter provides information required to implement the False Carriers attribute within the MAU managed object class of Clause 30 of the IEEE 802.3u specification.

Ethernet PHY False Carrier Sense Counter - MR20 (EPHYFCSCR)

Base n/a

Address 0x014

Type RO, reset 0x0000

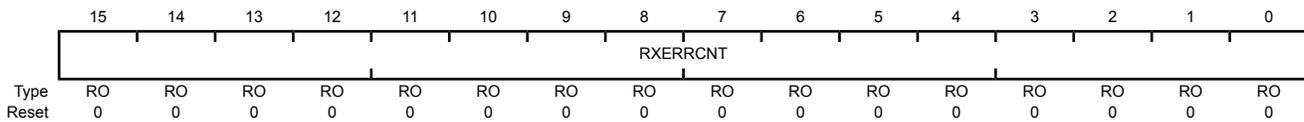

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|-------|---|
| 15:8 | reserved | RO | 0x0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 7:0 | FCSCNT | RO | 0x00 | False Carrier Event Counter This 8-bit counter increments on every false carrier event. This counter stops when it reaches its maximum count (0xFF). When the counter exceeds half full (0x7F), an interrupt event is generated. This register is cleared on read. |

Register 91: Ethernet PHY Receive Error Count - MR21 (EPHYRXERCNT), address 0x015

This counter provides information required to implement the Symbol Error During Carrier attribute within the PHY managed object class of Clause 30 of the IEEE 802.3u specification.

Ethernet PHY Receive Error Count - MR21 (EPHYRXERCNT)

Base n/a
 Address 0x015
 Type RO, reset 0x0000.0000

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|-------|--|
| 15:0 | RXERRCNT | RO | 0x0 | <p>Receive Error Count</p> <p>When a valid carrier is present (while <code>EN0RXDV</code> is active), and there is at least one occurrence of an invalid data symbol, this 16-bit counter increments for each receive error detected. The EPHYRXERCNT counter does not count in MII loopback mode. The counter stops when it reaches its maximum count of 0xFFFF. When the counter exceeds half-full (0x7FFF), an interrupt is generated. This register is cleared on read.</p> |

Register 92: Ethernet PHY BIST Control - MR22 (EPHYBISTCR), address 0x016

This register is used for Build-In Self Test (BIST) configuration. The BIST functionality provides Pseudo Random Bit Stream (PRBS) mechanism including packet generation generator and checker. Selection of the exact loopback point in the signal chain is also done in this register.

Ethernet PHY BIST Control - MR22 (EPHYBISTCR)

Register 96: Ethernet PHY BIST Control and Status 1 - MR27 (EPHYBICSR1), address 0x01B

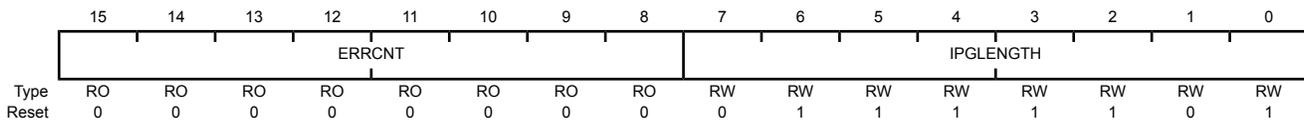

This register provides the total number of error bytes that are received by the PRBS checker and defines the Inter-Packet Gap (IPG) for the packet generator.

Ethernet PHY BIST Control and Status 1 - MR27 (EPHYBICSR1)

Base n/a

Address 0x01B

Type RW, reset 0x007D

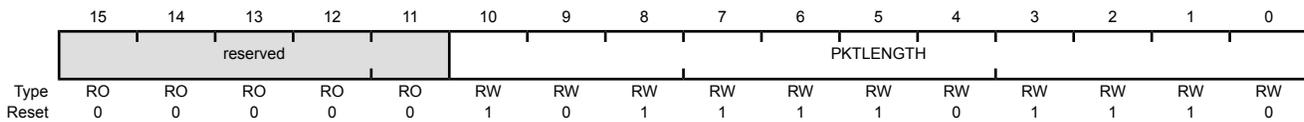

| Bit/Field | Name | Type | Reset | Description |
|-----------|-----------|------|-------|--|
| 15:8 | ERRCNT | RO | 0x00 | <p>BIST Error Count</p> <p>This field holds the number of erroneous bytes that were received by the PRBS checker. The value in this register is locked when a write is done to bit 15.</p> <p>When the PRBSM field in the EPHYBISCR register (0x0016) is set to zero, the count stops at 0xFF. See the EPHYBISCR register for further details.</p> |
| 7:0 | IPGLENGTH | RW | 0x7D | <p>BIST IPG Length</p> <p>Inter Packet Gap (IPG) Length defines the size of the gap (in bytes) between any 2 successive packets generated by the BIST. Default value is 0x7D, which is equal to 125 bytes.</p> |

Register 97: Ethernet PHY BIST Control and Status 2 - MR28 (EPHYBICSR2), address 0x01C

This register allows programming the length of the generated packets in bytes for the BIST mechanism

Ethernet PHY BIST Control and Status 2 - MR28 (EPHYBICSR2)

Base n/a
 Address 0x01C
 Type RW, reset 0x05EE

| Bit/Field | Name | Type | Reset | Description |
|-----------|-----------|------|-------|---|
| 15:11 | reserved | RO | 0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 10:0 | PKTLENGTH | RW | 0x5EE | BIST Packet Length The value of this register defines the size (in bytes) of every packet that is generated by the BIST. Default value is 0x5EE, which is equal to 1518 bytes. |

Register 98: Ethernet PHY Cable Diagnostic Control - MR30 (EPHYCDRCR), address 0x01E

This register provides the ability to start cable diagnostics and monitor its status.

Ethernet PHY Cable Diagnostic Control - MR30 (EPHYCDRCR)

Base n/a

Address 0x01E

Type RO, reset 0x0102

| | | | | | | | | | | | | | | | | |
|-------|-------|----------|----|----|----|----------|----|----|----------|----|----|----|------|------|----|----|
| | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | START | reserved | | | | LINKQUAL | | | reserved | | | | DONE | FAIL | | |
| Type | RW | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 |

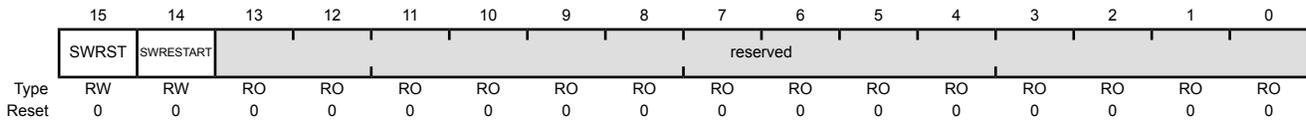

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|-------|---|
| 15 | START | RW | 0 | <p>Cable Diagnostic Process Start</p> <p>Diagnostic Start bit is cleared with raise of Diagnostic Done indication.</p> <p>Value Description</p> <p>0 Cable Diagnostic is disabled</p> <p>1 Start cable diagnostic measurement</p> |
| 14:10 | reserved | RO | 0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 9:8 | LINKQUAL | RO | 0x1 | <p>Link Quality Indication</p> <p>The value of these bits are valid only when link is active (when the LINK bit in the EPHYSTS register is a 0x1).</p> <p>Value Description</p> <p>0x0 reserved</p> <p>0x1 Good Quality Link Indication</p> <p>0x2 Mid- Quality Link Indication</p> <p>0x3 Poor Quality Link Indication</p> |
| 7:2 | reserved | RO | 0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 1 | DONE | RO | 1 | <p>Cable Diagnostic Process Done</p> <p>Value Description</p> <p>0 Diagnostic has not completed</p> <p>1 Indicates that the cable measurement process completed</p> |
| 0 | FAIL | RO | 0 | <p>Cable Diagnostic Process Fail</p> <p>Value Description</p> <p>0 Diagnostic has not failed</p> <p>1 Indicates that the cable measurement process failed</p> |

Register 99: Ethernet PHY Reset Control - MR31 (EPHYRCR), address 0x01F

This register allows the system to reset or restart the PHY by register access.

Ethernet PHY Reset Control - MR31 (EPHYRCR)

Base n/a
 Address 0x01F
 Type RW, reset 0x0000

| Bit/Field | Name | Type | Reset | Description |
|-----------|-----------|------|-------|--|
| 15 | SWRST | RW | 0 | Software Reset Value Description 0 Normal Operation. 1 Soft reset. This mode resets the digital portion of the PHY and all of the registers. This bit self clears after completion. |
| 14 | SWRESTART | RW | 0 | Software Restart Value Description 0 Normal Operation. 1 Restart PHY. This mode resets the digital portion of the PHY but no the registers. This bit self clears after completion of the restart. |
| 13:0 | reserved | RO | 0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |

Register 100: Ethernet PHY LED Configuration - MR37 (EPHYLEDCFG), address 0x025

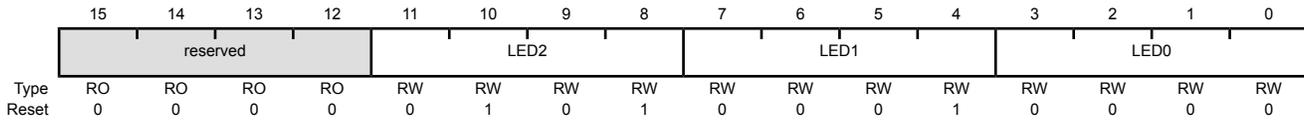

This register configures the LEDs provided in the PHY.

Ethernet PHY LED Configuration - MR37 (EPHYLEDCFG)

Base n/a

Address 0x025

Type RW, reset 0x0000.0510

| Bit/Field | Name | Type | Reset | Description | | | | | | | | | | | | | | | | | | | | | | |

25 Universal Serial Bus (USB) Controller

Important: The full USB chapter is under NDA. This chapter describes the module features at a high level. For a copy of the full NDA data sheet, follow the instructions in the *Non-Disclosure Agreement for the Tiva C Series TM4C129XKCZAD Microcontroller Data Sheet* (literature number [SPMS425](#)).

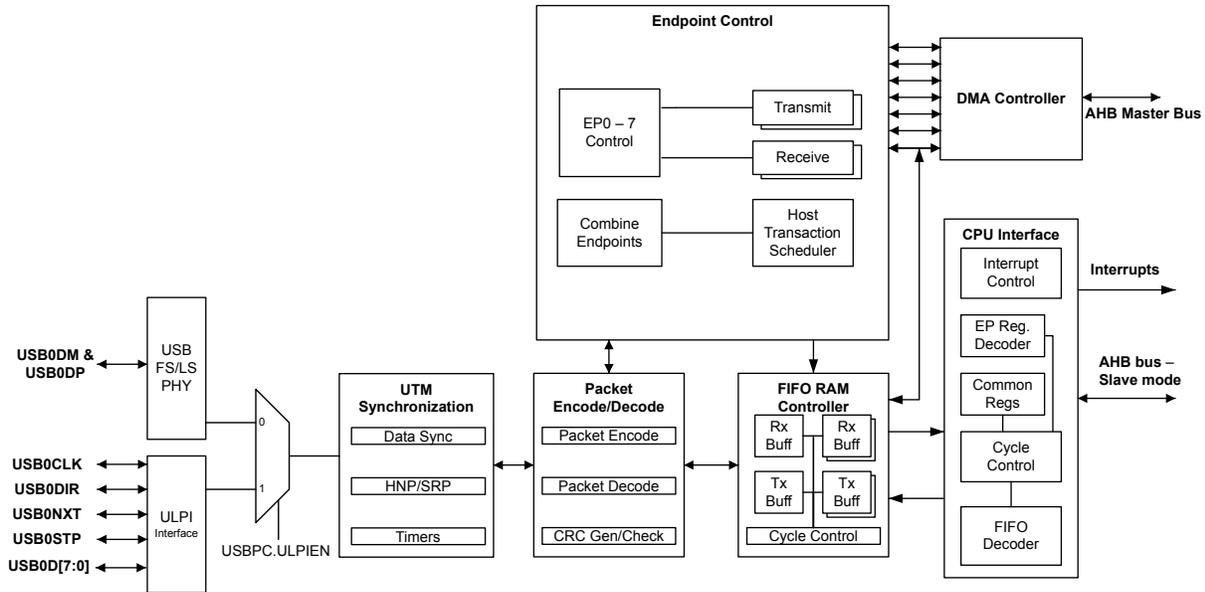

The TM4C129XKCZAD USB controller operates as a full-speed or low-speed function controller during point-to-point communications with USB Host, Device, or OTG functions. If the integrated ULPI interface is utilized, the USB can operate at high-speed. The controller complies with the USB 2.0 standard, which includes SUSPEND and RESUME signaling. 16 endpoints including two hard-wired for control transfers (one endpoint for IN and one endpoint for OUT) plus 14 endpoints defined by firmware along with a dynamic sizable FIFO support multiple packet queueing. USB DMA access to the FIFO allows minimal interference from system software. Software-controlled connect and disconnect allows flexibility during USB device start-up. The controller complies with OTG Standard's Session Request Protocol (SRP) and Host Negotiation Protocol (HNP).

The TM4C129XKCZAD USB module has the following features:

- Complies with USB-IF (Implementer's Forum) certification standards
- USB 2.0 high-speed (480 Mbps) operation with the integrated ULPI interface communicating with an external PHY
- Link Power Management support which uses link-state awareness to reduce power usage
- 4 transfer types: Control, Interrupt, Bulk, and Isochronous
- 16 endpoints
 - 1 dedicated control IN endpoint and 1 dedicated control OUT endpoint
 - 7 configurable IN endpoints and 7 configurable OUT endpoints
- 4 KB dedicated endpoint memory: one endpoint may be defined for double-buffered 1023-byte isochronous packet size
- VBUS droop detection and interrupt
- Integrated USB DMA with bus master capability
 - Up to eight RX Endpoint channels and up to eight TX Endpoint channels are available.
 - Each channel can be separately programmed to operate in different modes
 - Incremental burst transfers of 4-, 8-, 16- or unspecified length supported

25.1 Block Diagram

Figure 25-1. USB Module Block Diagram

25.2 Signal Description

The following table lists the external signals of the USB controller and describes the function of each. Some USB controller signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for these USB signals. The `AFSEL` bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 803) should be set to choose the USB function. The number in parentheses is the encoding that must be programmed into the `PMCn` field in the **GPIO Port Control (GPIOPCTL)** register (page 820) to assign the USB signal to the specified GPIO port pin. The `USB0VBUS` and `USB0ID` signals are configured by clearing the appropriate `DEN` bit in the **GPIO Digital Enable (GPIODEN)** register. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 772. The remaining signals (with the word "fixed" in the Pin Mux/Pin Assignment column) have a fixed pin assignment and function.

Note: When used in OTG mode, `USB0VBUS` and `USB0ID` do not require any configuration as they are dedicated pins for the USB controller and directly connect to the USB connector's VBUS and ID signals. If the USB controller is used as either a dedicated Host or Device, the `DEVMOD` field in the **USB General-Purpose Control and Status (USBGPCS)** register can be used to connect the `USB0VBUS` and/or `USB0ID` inputs to fixed levels internally, freeing the `PB0` and `PB1` pins for GPIO use. Note that `PB1` (`USB0VBUS`) is a 5-V tolerant signal as required. For proper self-powered Device operation, the VBUS value must still be monitored to assure that if the Host removes VBUS, the self-powered Device disables the D+/D- pull-up resistors. This function can be accomplished by connecting a standard GPIO to VBUS.

The termination resistors for the USB PHY have been added internally, and thus there is no need for external resistors. For a device, there is a 1.5 KOhm pull-up on the D+ and for a host there are 15 KOhm pull-downs on both D+ and D-.

Note: Port pins `PL6` and `PL7` operate as Fast GPIO pads, but have 4-mA drive capability only. GPIO register controls for drive strength, slew rate and open drain have no effect on these pins. The registers which have no effect are as follows: **GPIODR2R**, **GPIODR4R**, **GPIODR8R**, **GPIODR12R**, **GPIOSLR**, and **GPIOODR**. Refer to “General-Purpose Input/Outputs (GPIOs)” on page 772 and “Recommended GPIO Operating Characteristics” on page 2097 for more information.

Table 25-1. USB Signals (212BGA)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description |
|----------|----------------|--------------------------------|----------|-------------|---|
| USB0CLK | B17 | PB3 (14) | O | TTL | 60-MHz clock to the external PHY. |
| USB0D0 | G16 | PL0 (14) | I/O | TTL | USB data 0. |
| USB0D1 | H19 | PL1 (14) | I/O | TTL | USB data 1. |
| USB0D2 | G18 | PL2 (14) | I/O | TTL | USB data 2. |
| USB0D3 | J18 | PL3 (14) | I/O | TTL | USB data 3. |
| USB0D4 | H18 | PL4 (14) | I/O | TTL | USB data 4. |
| USB0D5 | G19 | PL5 (14) | I/O | TTL | USB data 5. |
| USB0D6 | B12 | PP5 (14) | I/O | TTL | USB data 6. |
| USB0D7 | D8 | PP4 (14) | I/O | TTL | USB data 7. |
| USB0DIR | C12 | PP3 (14) | O | TTL | Indicates that the external PHY is able to accept data from the USB controller. |
| USB0DM | B18 | PL7 | I/O | Analog | Bidirectional differential data pin (D- per USB specification) for USB0. |
| USB0DP | C18 | PL6 | I/O | Analog | Bidirectional differential data pin (D+ per USB specification) for USB0. |
| USB0EPEN | V5 R7 B3 | PA6 (5) PA7 (11) PD6 (5) | O | TTL | Optionally used in Host mode to control an external power source to supply power to the USB bus. |
| USB0ID | A16 | PB0 | I | Analog | This signal senses the state of the USB ID signal. The USB PHY enables an integrated pull-up, and an external element (USB connector) indicates the initial state of the USB controller (pulled down is the A side of the cable and pulled up is the B side). |
| USB0NXT | B13 | PP2 (14) | O | TTL | Asserted by the external PHY to throttle all data types. |
| USB0PFLT | R7 B2 | PA7 (5) PD7 (5) | I | TTL | Optionally used in Host mode by an external power source to indicate an error state by that power source. |
| USB0STP | A17 | PB2 (14) | O | TTL | Asserted by the USB controller to signal the end of a USB transmit packet or register write operation. |
| USB0VBUS | B16 | PB1 | I/O | Analog | This signal is used during the session request protocol. This signal allows the USB PHY to both sense the voltage level of VBUS, and pull up VBUS momentarily during VBUS pulsing. |

25.3 Register Map

Table 25-2 on page 1834 lists the registers. All addresses given are relative to the USB base address of 0x4005.0000. Note that the USB controller clock must be enabled before the registers can be programmed (see page 410). There must be a delay of 3 system clocks after the USB module clock is enabled before any USB module registers are accessed.

Note: Descriptions for all these registers can be found in the NDA version of the data sheet.

Table 25-2. List of Registers

| Offset | Name | Description |
|--------|----------------|--|
| 0x000 | USBFADDR | USB Device Functional Address |
| 0x001 | USBPOWER | USB Power |
| 0x002 | USBTXIS | USB Transmit Interrupt Status |

26 LCD Controller

The Liquid Crystal Display (LCD) Controller provides support for a variety of LCD and OLED panels. The TM4C129XKCZAD controller includes an LCD Controller with the following features:

- Character-based panels
 - Support for two character panels (CS0 and CS1) with independent and programmable bus timing parameters when in asynchronous Hitachi, Motorola, and Intel modes
 - Support for one character panel (CS0) with programmable bus timing parameters when in synchronous Motorola and Intel modes
 - Can be used as a generic 16-bit address/data interleaved MPU bus master with no external stall
- Passive matrix LCD panels
 - Panel types including STN, DSTN, and C-DSTN
 - AC Bias Control
- Active matrix LCD panels
 - Panel types including TN TFT
 - 1, 2, 4, or 8 bits per pixel with palette RAM and 16 or 24 bits per pixel without palette RAM
- OLED Panels
 - Passive Matrix (PM OLED) with frame buffer and controller IC inside the panel
 - Active Matrix (AM OLED)
- Bus mastering capability from either system SRAM or EPI memory.

26.1 Block Diagram

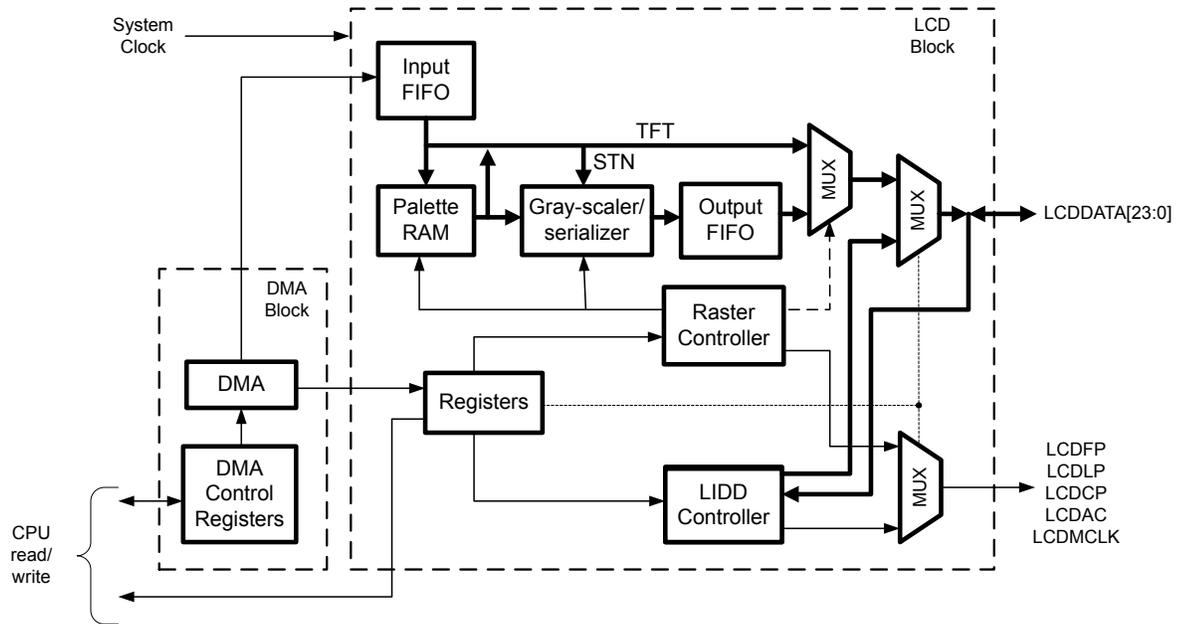

The LCD controller consists of two independent controllers, the Raster Controller and the LCD Interface Display Driver (LIDD) controller. Each controller operates independently from the other and only one of them is active at any given time.

- The Raster Controller provides a synchronous LCD interface. It provides timing and data for constant graphics refresh to a passive display. It supports a wide variety of monochrome and full-color display types and sizes by use of programmable timing controls, a built-in palette, and a gray-scale/serializer. Graphics data is processed and stored in frame buffers. A frame buffer is a contiguous memory block in the system. A built-in DMA engine supplies the graphics data to the Raster engine which, in turn, outputs to the external LCD device.
- The LIDD controller provides an asynchronous and/or synchronous interface depending on the mode the LIDD controller is operating in. It provides full-timing programmability of control signals (chip selects, read/write strobes, enable, direction) and output data.

Figure 26-1 on page 1841 shows the LCD controller details. The raster and LIDD Controllers are responsible for generating the correct external timing. The LCD DMA engine provides a constant flow of data from the frame buffer(s) to the external LCD panel via the Raster and LIDD Controllers. In addition, CPU access is provided to read and write registers.

The solid, thick lines in Figure 13-1 indicate the data path. For more information on the Raster Controller data path, see Figure 26-3 on page 1850 .

Figure 26-1. LCD Block Diagram

26.2 Signal Description

The following table lists the external signals of the LCD controller and describes the function of each.

Table 26-1. LCD Signals (212BGA)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description |
|-----------|------------|--------------------------|----------|-------------|--|
| LCDAC | N1 | PJ6 (15) | O | TTL | LCD AC bias or latch enable in Raster mode; Primary chip select (CS0)/Primary Enable (E0) in LIDD MPU/Hitachi mode |
| LDCDP | N5 | PR0 (15) | O | TTL | LCD Pixel Clock in Raster mode; read strobe or read/write strobe in LIDD mode |
| LCDDATA00 | P3 | PR4 (15) | I/O | TTL | LCD Data Pin 0 input/output. |
| LCDDATA01 | P2 | PR5 (15) | I/O | TTL | LCD Data Pin 1 input/output. |
| LCDDATA02 | U8 | PF7 (15) | I/O | TTL | LCD Data Pin 2 input/output. |
| LCDDATA03 | V8 | PR3 (15) | I/O | TTL | LCD Data Pin 3 input/output. |
| LCDDATA04 | W9 | PR6 (15) | I/O | TTL | LCD Data Pin 4 input/output. |
| LCDDATA05 | R10 | PR7 (15) | I/O | TTL | LCD Data Pin 5 input/output. |

Table 26-1. LCD Signals (212BGA) (continued)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description |
|-----------|------------|--------------------------|----------|-------------|---|
| LCDDATA06 | V9 | PS4 (15) | I/O | TTL | LCD Data Pin 6 input/output. |
| LCDDATA07 | T13 | PS5 (15) | I/O | TTL | LCD Data Pin 7 input/output. |
| LCDDATA08 | U10 | PS6 (15) | I/O | TTL | LCD Data Pin 8 input/output. |
| LCDDATA09 | R13 | PS7 (15) | I/O | TTL | LCD Data Pin 9 input/output. |
| LCDDATA10 | W10 | PT0 (15) | I/O | TTL | LCD Data Pin 10 input/output. |
| LCDDATA11 | V10 | PT1 (15) | I/O | TTL | LCD Data Pin 11 input/output. |
| LCDDATA12 | U12 | PN7 (15) | I/O | TTL | LCD Data Pin 12 input/output. |
| LCDDATA13 | T12 | PN6 (15) | I/O | TTL | LCD Data Pin 13 input/output. |
| LCDDATA14 | H17 | PJ2 (15) | I/O | TTL | LCD Data Pin 14 input/output. |
| LCDDATA15 | F16 | PJ3 (15) | I/O | TTL | LCD Data Pin 15 input/output. |
| LCDDATA16 | F18 | PJ4 (15) | O | TTL | LCD Data Pin 16 output. |
| LCDDATA17 | E17 | PJ5 (15) | O | TTL | LCD Data Pin 17 output. |
| LCDDATA18 | E18 | PT2 (15) | O | TTL | LCD Data Pin 18 output. |
| LCDDATA19 | F17 | PT3 (15) | O | TTL | LCD Data Pin 19 output. |
| LCDDATA20 | D12 | PS0 (15) | O | TTL | LCD Data Pin 20 output. |
| LCDDATA21 | D13 | PS1 (15) | O | TTL | LCD Data Pin 21 output. |
| LCDDATA22 | B14 | PS2 (15) | O | TTL | LCD Data Pin 22 output. |
| LCDDATA23 | A14 | PS3 (15) | O | TTL | LCD Data Pin 23 output. |
| LCDFP | N4 | PR1 (15) | O | TTL | LCD Frame Clock or VSYNC in Raster mode; Address Latch Enable in LIDD mode |
| LCDLP | N2 | PR2 (15) | O | TTL | LCD Line Clock or HSYNC in Raster mode; Write Strobe or Direction bit in LIDD mode |
| LCDMCLK | T8 | PF6 (15) | O | TTL | LCD Memory Clock/Secondary chip Select (CS1)/Secondary Enable (E1) in LIDD Synchronous/Async MPU/Hitachi mode |

The following table gives a more detailed summary of how the signals are used in each mode. These features are also discussed in the functional description section.

Table 26-2. LCD External Signal Details

| Signal | Type | Mode | Function |
|------------------|--------|-------------|--|
| LCDFP (VSYNC) | Output | Raster Mode | This signal functions as a frame clock the LCD uses to signal the start of a new frame of pixels. This signal is also used by TFT displays as the vertical synchronization signal. |
| | | LIDD Mode | This signal functions as an Address Latch Enable (ALE) |
| LCDLP (HSYNC) | Output | Raster Mode | This signal functions as a line clock the LCD uses to signal the end of a line of pixels. This signal is also used by TFT displays as the horizontal synchronization signal. |
| | | LIDD Mode | This signal functions as a write strobe or direction bit depending on the interface mode. |

Table 26-2. LCD External Signal Details (continued)

| Signal | Type | Mode | Function |
|------------------------|--------------|-------------|--|
| LCDCP (Pixel clock) | Output | Raster Mode | This signal functions as the pixel clock the LCD uses to clock the pixel data into the line shift register. In passive mode, the pixel clock transitions only when valid data is available on the data lines. In active mode, the pixel clock transitions continuously, and the LCDAC pin is used as an output enable to signal when data is available on the LCD pin. |
| | | LIDD Mode | This signal functions as a read strobe (RS) or read/write strobe (RS/WS) depending on the interface mode. |
| LCDAC | Output | Raster Mode | This signal functions as the AC-bias used to trigger the LCD to switch the polarity of the power supplies to the row and column axis of the screen to counteract DC offset. The signal is used in TFT mode as the output enable to signal when data is latched from the data pins using the pixel clock. LIDD Character: Primary Enable Strobe (E0) LIDD Graphics: Chip Select 0 (CS0) |
| | | LIDD Mode | This signal functions as the primary enable (E0) or Hitachi mode and the primary chip select (CS0) depending on the interface mode. |
| LCDMCLK | OUT | LIDD Mode | This signal is not used in Raster mode, but is used as a secondary Enable Strobe (E1) or Chip Select (CS1) depending on the interface mode. |
| LCDDATA | Output | Raster Mode | These signals function as the LCD data bus providing 4-, 8-, 16-, or 24-bit data path. For monochrome displays, each signal represents a pixel; for passive color displays, groupings of three signals represent one pixel (red, green, and blue). LCDDATA[3:0] are used for monochrome displays of 2, 4, and 8 BPP; LCDDATA[7:0] are used for color STN displays and LCDDATA[15:0] or LCDDATA[23:0] are used for active (TFT) mode. |
| | Output/Input | LIDD Mode | These signals function as the read and write path for the command and data registers. |

Table 26-3 on page 1843 details MODESEL programming for the alternate pin functions in LIDD mode. For further programming information refer to the LCDLIDDCTL register.

Table 26-3. LCD Alternate Signal Functions in LIDD Mode

| PIN | MODE = 0x0 | MODE = 0x1 | MODE = 0x2 | MODE = 0x3 | MODE = 0x4 |
|---------|------------|------------|------------|------------|------------|
| LDCP | RS/WS | RS/WS | RS | RS | N/A |
| LCDLP | DIR | DIR | WS | WS | DIR |
| LCDFP | ALE | ALE | ALE | ALE | ALE |
| LCDAC | CS0 | CS0 | CS0 | CS0 | E0 |
| LCDMCLK | MCLK | CS1 | MCLK | CS1 | E1 |

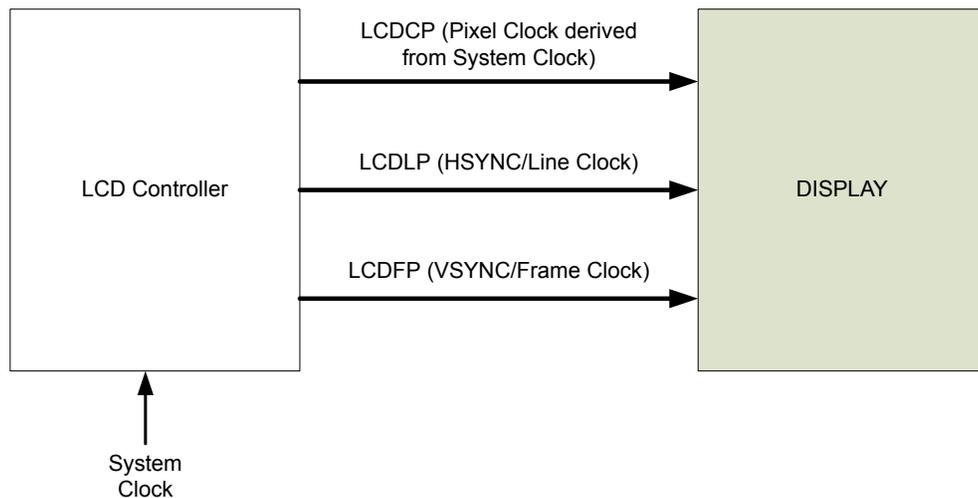

26.3 Functional Description

The following sections describe the functional capability of the LCD Controller

26.3.1 Clocking

This section details the various clocks and signals. Figure 26-2 on page 1844 shows the input and output LCD controller clocks.

Figure 26-2. Input and Output Clocks

26.3.1.1 Pixel Clock (LCDCP signal)

The pixel clock (LCDCP) frequency is derived from the system clock, which is the internal reference clock (MCLK) to the LCD module. The pixel clock is used by the LCD display to clock the pixel data into the line shift register. The formula used for the pixel clock is:

$$\text{LCDCP} = \text{System Clock} / \text{CLKDIV}$$

where CLKDIV is a field in the **LCD Control (LCDCTL)** register. The value of CLKDIV should not be 0 or 1 in Raster Mode. The pixel clock operates differently depending on the mode of the LCD controller:

- Passive (STN) mode: LCDCP only transitions when valid data is available for output. It does not transition when the horizontal clock (HSYNC) is asserted or during wait state insertion.
- Active (TFT) mode: LCDCP continuously toggles as long as the Raster Controller is enabled.

26.3.1.2 HSYNC Horizontal Clock (LCDLP signal)

HSYNC (LCDLP signal) toggles after all pixels in a horizontal line have been transmitted to the LCD and a programmable number of pixel clock wait states have elapsed both at the beginning and end of each line. The **LCD Raster Timing 0 (LCDRASTRIM0)** register, offset 0x02C, fully defines the behavior of this signal.

HSYNC can be programmed to be synchronized with the rising or falling edge of the pixel clock (LCDCP). The PXLCLKCTL and PSYNCRF bits in the **LCD Raster Timing 2 (LCDRASTRIM2)** register, offset 0x034, are used to configure the synchronization.

- Active (TFT) mode: The horizontal clock or the line clock is also used by TFT displays as the horizontal synchronization signal (HSYNC).

The timings of the horizontal clock (line clock) pins are programmable to support:

- Delay insertion both at the beginning and end of each line

- Line clock polarity
- Line clock pulse width, driven on rising or falling edge of pixel clock

26.3.1.3 VSYNC Vertical Clock (LCDFP signal)

VSYNC (LCDFP signal) toggles after all lines in a frame have been transmitted to the LCD and a programmable number of line clock cycles has elapsed both at the beginning and end of each frame. The **LCD Raster Timing 1 (LCDRASTRIM1)** register, offset 0x030, fully defines the behavior of this signal.

VSYNC can be programmed to be synchronized with the rising or falling edge of LCDCP pixel clock. The `PXLCLKCTL` and `PSYNCRF` bits in the **LCD Raster Timing 2 (LCDRASTRIM2)** register, offset 0x034, are used to configure the synchronization.

- Passive (STN) mode: The vertical, or frame, clock toggles during the first line of the screen.
- Active (TFT) mode: The vertical, or frame, clock is also used by TFT displays as the vertical synchronization signal (VSYNC). The timings of the vertical clock pins are programmable to support:
 - Delay insertion both at the beginning and end of each frame
 - Frame clock polarity

26.3.1.4 LCD AC Bias Enable (LCDAC)

- Passive (STN) mode: To prevent a DC charge within the screen pixels, the power and ground supplies of the display are periodically switched. The Raster Controller signals the LCD to switch the polarity by toggling this pin.
- Active (TFT) mode: This signal acts as an output enable (OE) signal. It is used to signal the external LCD that the data is valid on the data bus.

26.3.2 LCD DMA Engine

The LCD DMA engine provides the capability to output graphics data to constantly refresh the external LCD display, without burdening the CPU, via interrupts or a firmware timer. It operates on one or two frame buffers, which are set up during initialization. Using two frame buffers (ping-pong buffers) enables the simultaneous operation of outputting the current video frame to the external display and updating the next video frame. The ping-pong buffering approach is preferred in most applications.

When the Raster Controller is used, the LCD DMA engine reads data from a frame buffer and writes it to the input FIFO. The Raster Controller requests data from the FIFO for frame refresh, so the DMA is used to keep the FIFO filled.

When the LIDD controller is used, the LCD DMA engine accesses the LIDD controller's address and/or data registers. The following steps are needed to configure the DMA engine:

1. Configure the data format in the **LCD DMA Control (LCDDMACTL)** register, offset 0x040.
2. Configure frame buffer 0 by programming the **LCD DMA Frame Buffer 0 Base Address (LCDDMABAFB0)** register, offset 0x044, and the **LCD DMA Frame Buffer 0 Ceiling Address (LCDDMACAFB0)** register, offset 0x048

3. Configure frame buffer 1 by programming the **LCD DMA Frame Buffer 1 Base Address (LCDDMABAFB1)** register, offset 0x04C, and the **LCD DMA Frame Buffer 1 Ceiling Address (LCDDMACAFB1)** register, offset 0x050.

In addition, depending on whether the application is operating in LIDD mode or Raster Mode, the **LCDLIDDCTL** or the **LCDRASTRCTL** register should be configured appropriately, along with all of the timing registers. To enable DMA transfers, the **DMAEN** bit in the **LCDLIDDCTL** or the **LCDEN** bit in the **LCDRASTRCTL** register should be written with a 1.

26.3.2.1 Interrupts

Interrupts in this LCD module are related to DMA engine operation. Five registers are used to control and monitor the interrupts:

- **LCDLIDDCTL** and **LCDRASTRCTL** registers enable and disable individual features that can generate interrupts.
- The **LCD Interrupt Raw Status and Set Register (LCDRISSET)** register, offset 0x058, collects all of the interrupt status information.
- The **LCD Interrupt Status and Clear (LCDMISCLR)** register, offset 0x05C, is used to read and clear the status of the masked interrupt triggers.
- The **LCD Interrupt Mask (LCDIM)** register, offset 0x060, is used to control whether an interrupt source is masked or not.

LIDD Mode

When operating in LIDD mode, the DMA engine generates one interrupt signal every time the specified frame buffer has been transferred completely. The **EOF1**, **EOF0** and **DONE** bits of the **LCDRISSET** register reflect the interrupt signal, regardless of whether or not the interrupt is enabled.

Raster Mode

When operating in Raster mode, the DMA engine can generate the interrupts in the following scenarios:

- **Output FIFO under-run:** This interrupt occurs when the DMA engine cannot keep up with the data rate consumed by the LCD (which is determined by the **LCDCP**.) This is likely due to a system memory throughput issue or an incorrect **LCDCP** setting. The **FIFOU** bit in **LCD Interrupt Raw Status and Set Register (LCDRISSET)** register is set when this error occurs. This bit is cleared by disabling the Raster Controller, that is clearing the **LCDEN** bit in **LCD Raster Control (LCDRASTRCTL)** register.
- **Frame Synchronization lost:** This error happens when the DMA engine attempts to read what it believes to be the first word of the video buffer but the data cannot be recognized as such. This situation can be caused by an invalid frame buffer address or an invalid BPP value. The **SYNC** bit in the **IRQSTATUS_RAW** register is set when such an error is detected. This field is cleared by disabling the Raster Controller (clearing the **LCDEN** bit in **LCD Raster Control (LCDRASTRCTL)** register).
- **Palette loaded:** This interrupt can be generated when the palette is loaded into the memory by the DMA engine. At the same time, the **PALLOAD** bit in the **LCD Interrupt Raw Status and Set Register (LCDRISSET)** register is set. In data-only (**PALMODE** = 0x2) and palette-plus-data (**PALMODE** = 0x0) modes, writing 0 to this bit clears the interrupt. In the palette-only (**PALMODE**

= 0x1) mode, this bit is cleared by disabling the Raster Controller (clearing the `LCDEN` bit in the **LCD Raster Control (LCDRASTRCTL)** register).

- **AC Bias transition:** If the `ACBI` field in the **LCD Raster Timing 2 (LCDRASTRTIM2)** register is programmed with a nonzero value, an internal counter is loaded with this value and starts to decrement each time `LCDAC` (AC-bias signal) switches its state. When the counter reaches zero, the `ACBS` bit in the **LCD Interrupt Raw Status and Set Register (LCDRISSET)** register is set, which delivers an interrupt signal to the system interrupt controller (if the interrupt is enabled.) The counter reloads the value in `ACBI` field, but does not start to decrement until the `ABC` bit is cleared by writing 0 to this bit.
- **Frame transfer completed:** When one frame of data is transferred completely, the `DONE` bit in the **LCD Interrupt Raw Status and Set Register (LCDRISSET)** register is set. This bit is cleared by disabling the Raster Controller (clearing the `LCDEN` bit in **LCD Raster Control (LCDRASTRCTL)** register). The `EOF0` and `EOF1` bits in **LCD Interrupt Raw Status and Set Register (LCDRISSET)** register are set accordingly.

Note that the function enable bits are in the in **LCD Raster Control (LCDRASTRCTL)** register and must be set in order to generate an interrupt to the CPU.

26.3.3 LIDD Bus Operation

The integrated LCD Interface Display Drive (LIDD) Controller has programmable timing parameters that support a wide variety of character-based LCD panels. Alternatively, the DMA module can be used to mimic the CPU and perform a sequence of write-only data bus transactions to the character-based LCD panel.

LIDD mode is enabled by clearing the `LCDMODE` bit in the **LCD Control (LCDCTL)** register.

LIDD Controller operation is summarized as follows:

- During initialization, the **LCD LIDD CS0 Configuration (LIDDCS0CFG)** and **LCD LIDD CS1 Configuration (LIDDCS1CFG)** registers are configured to match the requirements of the LCD panel being used.
- During normal operation, the CPU writes display data to the **LIDD CS0 Data Read/Write Initiation (LIDDCS0DATA)** and **LIDD CS1 Data Read/Write Initiation (LIDDCS1DATA)** registers. The LIDD interface converts the CPU write into the proper signal transition sequence for the display, as programmed earlier. Note that the first CPU write should send the beginning address of the update to the LCD panel and the subsequent writes update data at display locations starting from the first address and continuing sequentially. Note that DMA may be used instead of CPU.
- The LIDD Controller is also capable of reading back status or data from the LCD panel, if the latter has this capability. This is set up and activated in a similar manner to the write function described above.

Table 26-4 on page 1848 describes how the signals are used to interface to external LCD modules, which are configured by the **LCDLIDDCTL** register.

Table 26-4. LIDD I/O Name Map

| Display Type | Interface Type | Data Bits | LCDLIDCTL[2:0] | Signal Name | LCD Display I/O Name | LCD Display I/O Description |
|---------------------------------|----------------|-----------|----------------|---------------|---------------------------------------|--|
| Character Display | HD44780 Type | 4 | 0x4 | LCDDATA[7:4] | DATA[7:4] | LCD Data Bus (length defined by instruction) |
| | | | | LCDAC | E (or E0) | Enable Strobe (first display) |
| | | | | LCDLP | R/ \bar{W} | Read/Write |
| | | | | LCDFP | RS | Register Select (Data/not Instruction) |
| | | | | LCDMCLK | E1 | Enable Strobe (second display optional) |
| Character Display | HD44780 Type | 8 | 0x4 | LCDDATA[7:0] | DATA[7:0] | LCD Data Bus (length defined by instruction) |
| | | | | LCDAC | E (or E0) | Enable Strobe (first display) |
| | | | | LCDLP | R/ \bar{W} | Read/Write |
| | | | | LCDFP | RS | Register Select (Data/not Instruction) |
| | | | | LCDMCLK | E1 | Enable Strobe (second display optional) |
| Micro Interface Graphic Display | 6800 Family | Up to 16 | 0x1 | LCDDATA[15:0] | DATA[15:0] | LCD Data Bus (16 bits always available) |
| | | | | LCDCP | E | Enable Clock |
| | | | | LCDLP | R/ \bar{W} | Read/Write |
| | | | | LCDFP | A0 | Address/Data Select |
| | | | | LCDAC | CS (or CS0) | Chip Select (first display) |
| | | | LCDMCLK | CS1 | Chip Select (second display optional) | |
| | | | 0x0 | LCDMCLK | None | Synchronous Clock (optional) |
| Micro Interface Graphic Display | 8080 Family | Up to 16 | 0x3 | LCDDATA[15:0] | DATA[15:0] | LCD Data Bus (16 bits always available) |
| | | | | LCDCP | RD | Read Strobe |
| | | | | LCDLP | WR | Write Strobe |
| | | | | LCDFP | A0 | Address/Data Select |
| | | | | LCDAC | CS (or CS0) | Chip Select (first display) |
| | | | LCDMCLK | CS1 | Chip Select (second display optional) | |
| | | | 0x2 | LCDMCLK | None | Synchronous Clock (optional) |

26.3.4 Raster Control

The Raster mode is enabled by setting the MODESEL bit in the **LCD Control (LCDCTL)** register. The following table shows the active external signals when this mode is active:

Table 26-5. Operation Modes Supported by Raster Controller

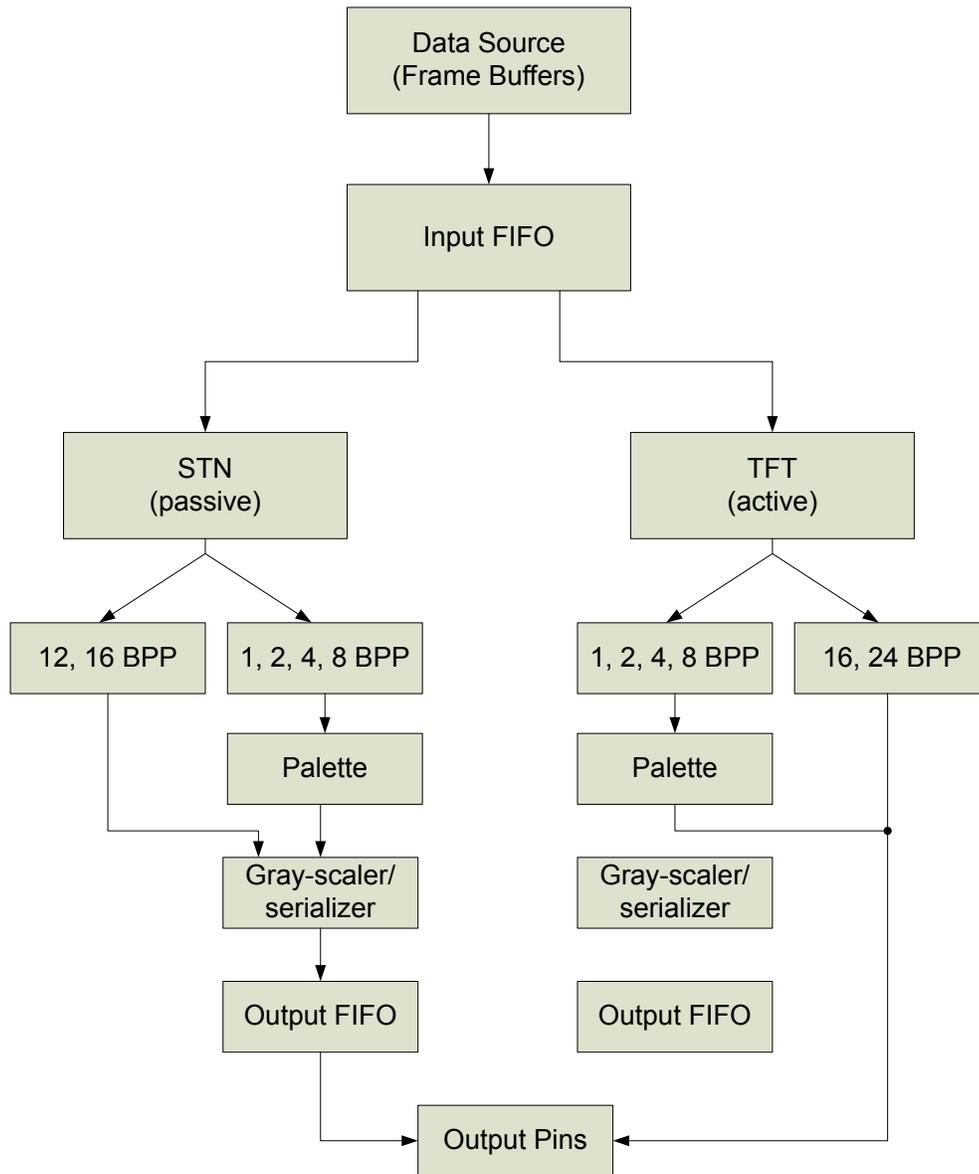

| Interface | Data Bus Width | RASTERCTRL [9, 7, 1] | Signal Name | Description |
|--------------------------|----------------|----------------------|-------------------|-------------------------------|
| Passive (STN) Mono 4-bit | 4 | 001 | LCDDATA[3 : 0] | Data Bus |
| | | | LCDCP | Pixel Clock |
| | | | LCDLDP | Horizontal clock (line clock) |
| | | | LCDFP | Vertical clock (frame clock) |
| | | | LCDAC | AC Bias |
| | | | LCDMCLK | Not used |
| Passive (STN) Mono 8-bit | 8 | 101 | LCDDATA[7 : 0] | Data Bus |
| | | | LCDCP | Pixel Clock |
| | | | LCDLDP | Horizontal clock (line clock) |
| | | | LCDFP | Vertical clock (frame clock) |
| | | | LCDAC | AC Bias |
| | | | LCDMCLK | Not used |
| Passive (STN) Color | 8 | 100 | LCDDATA[7 : 0] | Data Bus |
| | | | LCDCP | Pixel Clock |
| | | | LCDLDP | Horizontal clock (line clock) |
| | | | LCDFP | Vertical clock (frame clock) |
| | | | LCDAC | AC Bias |
| | | | LCDMCLK | Not used |
| Active (TFT) Color | 16 | x10 | LCDDATA[15 : 0] | Data Bus |
| | | | LCDCP | Pixel Clock |
| | | | LCDLDP | Horizontal clock (line clock) |
| | | | LCDFP | Vertical clock (frame clock) |
| | | | LCDAC | AC Bias |
| | | | LCDMCLK | Not used |

26.3.4.1 Logical Data Path

The block diagram of the Raster controller is shown in Figure 26-1 on page 1841. Figure 26-3 on page 1850 illustrates its logical data path for various operation modes (passive (STN) versus active (TFT) and various BPP size). Figure 26-3 on page 1850 shows that:

- The gray-scaler/serializer and output FIFO blocks are bypassed in active (TFT) modes.
- The palette is bypassed in both 12- and 16-BPP modes.

Figure 26-3. LCD Raster Data Path

In summary:

- The display image is stored in frame buffers.
- The built-in DMA engine constantly transfers the data stored in the frame buffers to the input FIFO.
- The Raster Controller relays data to the external pins according to the specified format.

26.3.5 LCD Frame Buffer

The LCD controller has the option to use the internal SRAM memory or external memory through the EPI interface to hold the frame buffer. The frame buffer is a contiguous memory block, storing enough data to fill a full LCD screen. The frame buffer contains the palette look-up table (palette RAM) and the frame data for a given source image. When moving data into the LCD, the `PALMODE` bit in the **LCD Raster Control (LCDRASTRCTL)** register can be configured for palette and data loading, palette loading only or data loading only.

Note: When using the LCD with EPI to interface to external memory, the external code address space 0x1000.0000 must be selected by programming the `ECADR` field to 0x1 in the **EPI Address Map (EPIADDRMAP)** register at EPI offset 0x01C.

26.3.6 Palette RAM

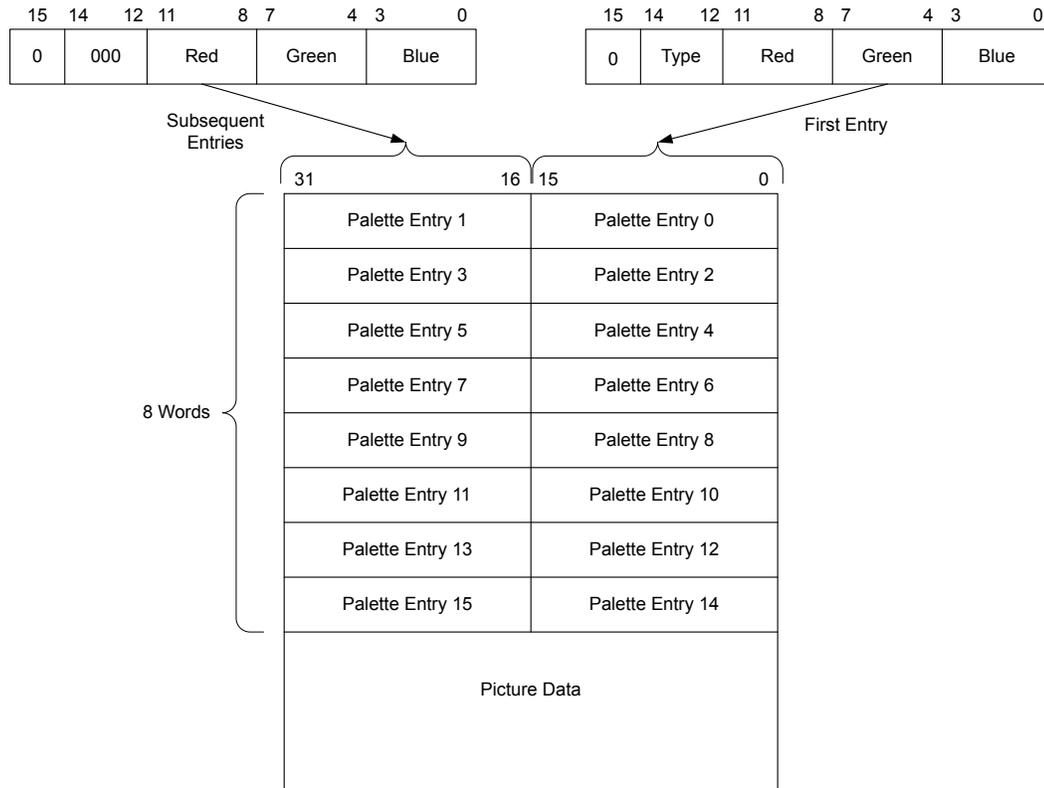

The palette RAM is a programmable cross reference table that maps a small set of input codes into a larger set of output codes. For active matrix displays, the palette RAM programmed in the LCD is used only for color source images. For passive matrix displays, the palette RAM is used for both grayscale and color source images. For color components, the passive matrix mode only supports, 4 bits per color component. 1, 2, 4, and 8 bit per pixel (bpp) source images always use the palette. 12, 16, and 24 bits per pixel do not use the palette RAM, since raw data transfers occur.

The LCD palette RAM uses a 12-bit output code such that there is a possibility of 4096 color options to choose from. Depending on the bpp frame storage of palette RAM, two, four, 16, or 256 palette colors can be stored in the palette RAM.

26.3.6.1 Palette RAM Structure for 1, 2, and 4 Bits Per Pixel

When palette RAM is enabled for 1, 2, and 4 bpp frame storage, the palette buffer is 16 word entries, where the upper half of the word is unused. The first entry of the palette RAM contains the encoding for the palette type (1, 2, 3, 6, or 12/16/24) of the stored picture on bits [14:12], as well as the first input code for one palette entry (bits [11:0]). Subsequent entries only contain the input codes for next palette entries. Figure 26-4 on page 1852 shows the frame buffer structure.

Figure 26-4. Palette RAM Structure for 1, 2, and 4 Bits Per Pixel

Note that for 1 bpp source pictures, the first two palette entries are valid; for 2 bpp sources, the first four palette entry sources are valid; for 4 bpp, all 16 palette entries are valid. Even if the palette entries are not valid for a particular type, there is a fixed number of 8 words reserved for the palette RAM.

The first palette entry represents the RGB value for the source pixel encoded as 0x0. The second palette entry represents the RGB value for the source pixel encoded as 0x1, and so on, such that the sixteenth palette entry is used to represent the RGB value for a pixel encoded as 0xF.

Source data encoded as 12, 16, or 24 bpp do not use the palette RAM since the encoded data already represents the actual RGB values. However, 16 palette RAM entries still precede the picture data in this case and the first palette entry must still define the bpp in bits [14:12]. The type field encoding is defined below in Table 26-6 on page 1852

Table 26-6. Type Encoding in Palette Entry 0 Buffer

| First Palette RAM Entry [14:12] | Source Image Type |
|---------------------------------|-------------------|
| 0x0 | 1 bpp |
| 0x1 | 2 bpp |
| 0x2 | 4 bpp |
| 0x3 | 8 bpp |
| 0x4 | 12, 16, or 24 bpp |

26.3.6.2 Palette RAM Structure for 8 Bits Per Pixel

For image sources that are 8 bpp, 256 palette entries (2^8) are required. This structure of the palette RAM is similar to the one described for 1, 2, 4, or 4 bpp except that the palette requires 256 entries (128 words), instead of 16. The first palette entry again contains the "type" definition of the picture along with the RGB values in bits [11:0].

LCD RAM Configuration

The LCD RAM can be configured to hold palette only, picture data only or both palette and picture data. Depending on the mode, the RAM is used differently:

- **Palette Only:** The `PALMODE` field in the **LCD Raster Control (LCDRASTRCTL)** register is programmed to 0x01. If the type field in the first palette entry is for 1, 2, 4, or 12/16/24 bpp, an 8 word palette buffer will be read from DDR by the DMA. If the bpp field in the first entry is 8 bpp, a 128 word palette will be loaded by the DMA. Note that the **DMA Frame Buffer n Base Address (LCDDMABAn)** and **LCD DMA Frame Buffer n Ceiling Address (LCDMACAn)** registers must encompass the palette information size. Note that although an 8 word buffer is created for 12/16/24 bpp, it is ignored during data transfers.
- **Data Only:** When `PALMODE` is programmed to 0x10, the bpp field from the last palette read is used. Thus, a single palette in DDR can be associated with multiple stored pictures in DDR, enabling the palette loading to occur once (`PALMODE` = 0x01) and subsequent data-only frame buffers to be transferred by the DMA into the RAM (`PALMODE` = 0x10). For 12/16/24 bpp frames the bpp field in the previously read palette RAM buffer is irrelevant.
- **Palette and Data:** When the `PALMODE` encoding is 0x00, the frame buffer is comprised of palette data followed immediately by pixel information. For 12, 14, and 24 bit (packed or unpacked) raw formats, an 8 word palette is prepended to the pixel data. Thus, palette information will be read from DDR even though it is not applicable data and the configuration will look similar to Figure 26-4 on page 1852.

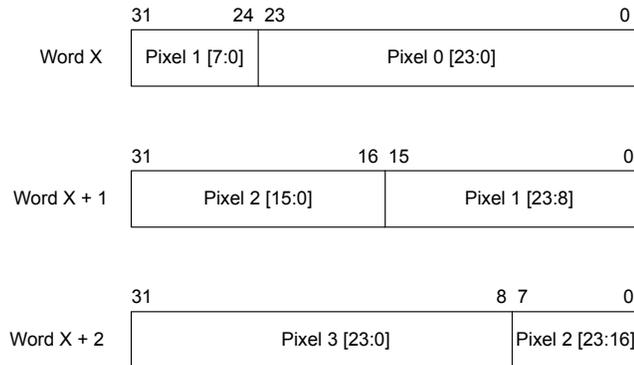

Raw Data and Color Component Formats

Depending on the value programmed in the raster control register you can have different color formats. Raw data formats are used for active matrix panels. The LCD controller supports, 24 bpp, 16 bpp and 12 bpp raw formats.

Note: The TYPE code in the first palette entry must be set to "1XX" for 12/16/24 bpp raw data formats.

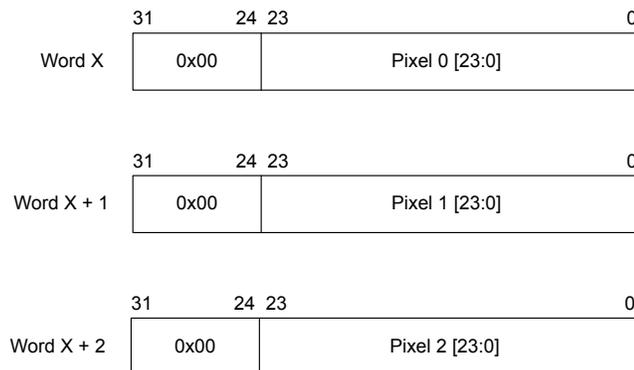

Data Format for 24 bpp

For raw formats used in active matrix panels, the palette RAM provides a 12 bpp output, or a color depth of 12 bits (4096 colors per pixel). Data formats of 24 bpp can be stored in packed or unpacked format. In packed format, four 24 bit pixels are stored in 3 contiguous 32-bit words (also called a quad-pixel triplet) in DDR, as show in Figure 26-5 on page 1854.

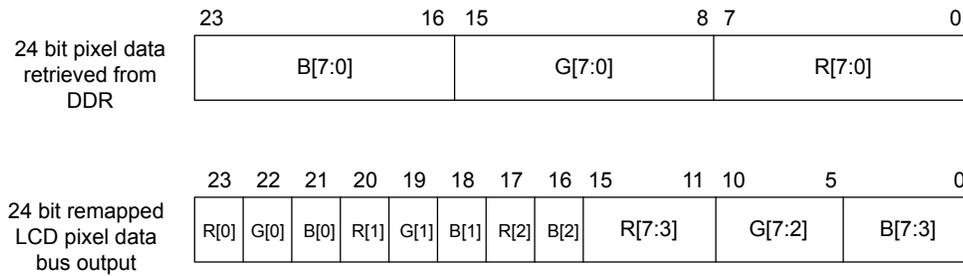

Figure 26-5. 24 bpp Packed Data Format

When using a 24 bit packed format, four consecutive pixels provide three word-aligned accesses for the DMA. If the `MSBPPL` and `PPL` bits in the `LCDRASTRTIM0` register are programmed to a multiple of 16, then the `MSBLPP` and `LPP` bits of the `LCDRASTRTIM1` and `LCDRASTRTIM2` register must follow a multiple of 16 so that the DMA can access the data using word-aligned accesses.

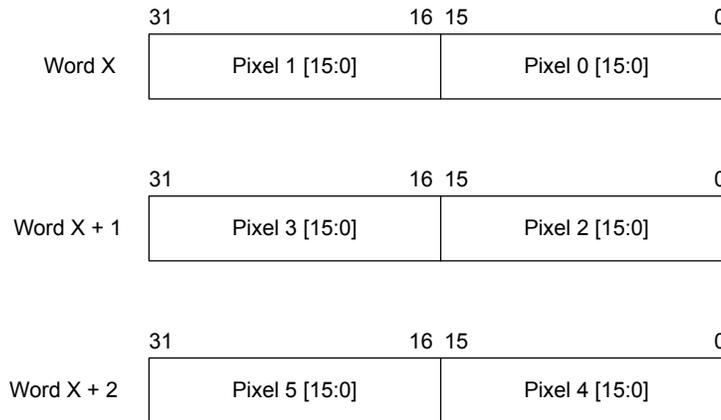

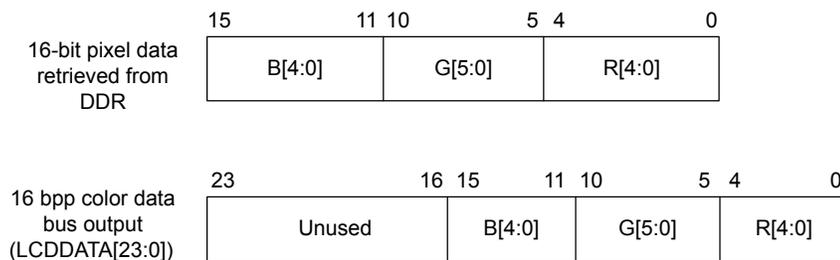

When `LCDTFT = 0x1`, `TFT24UPCK = 0x1` and `TFT24 = 0x1` in the `LCDRASTRCTL` register, 24 bit unpacked format is used. In this mode, each 24 bpp data is stored in a 32 bit word, with the upper 8 bits unused. Figure 26-6 on page 1854 shows the unpacked implementation.

Figure 26-6. 24 bpp Unpacked Data Format

For 24 bpp color components, data is stored in the DDR in B-G-R order with each color representing 8 bits. When the data is transferred to the LCD pixel data bus (`LCDDATA[23:0]`), the output is transposed such that a portion of the color components are now displayed on `LCDDATA [15:0]` in RGB565 format. The three least significant bits of the RGB 24-bit data are prepended to RGB565 data on `LCDDATA[23:15]`. The transposition of data is shown in Figure 26-7 on page 1855.

Figure 26-7. 24 bpp Color RGB Remapping on LCDDATA[23:0]**Data format for 16 bpp**

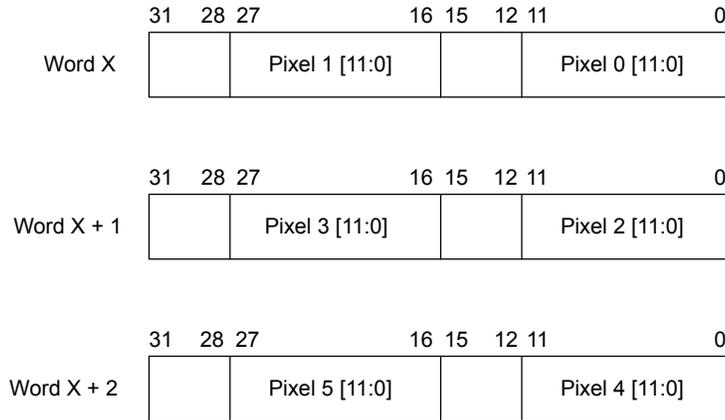

The LCD controller is configured to support 16 bpp raw data format when `TFT24 = 0x0`, `LCDTFT = 0x1`, `TFTMAP = 0x0` in the `LCDRSTRCTL` register. Two 16 bpp raw data pixels can be stored in one word in DDR. The configuration is shown in Figure 26-8 on page 1855. For color component ordering, pixel data is in a RGB565 configuration and is output on the LCD pixel data bus `LCDDATA [15:0]` in the same order. `LCDDATA` bits [23:16] are undefined in 16 bpp mode. Figure 26-9 on page 1855 shows the configuration of the pixel data retrieved from memory and LCD bus output.

Figure 26-8. 16 bpp Data Format**Figure 26-9. 16 bpp Color Component Ordering**

Data Format for 12 bpp

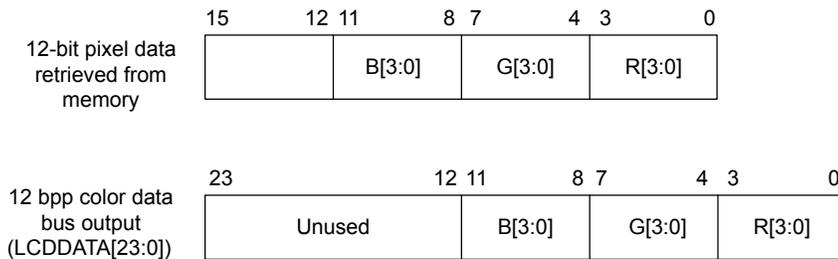

Two pixel data are stored in each 32-bit word in memory. The upper four bits in each 16-bit halfword are unused. Figure 26-10 on page 1856 shows the 12bpp data format.

Figure 26-10. 12 bpp Data Format

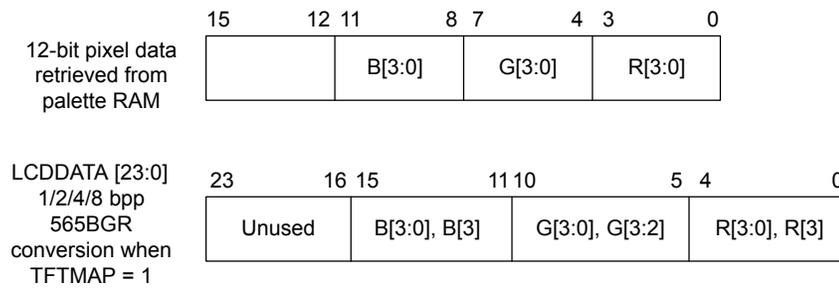

12 bpp color format has 4 pixels per Red, Green and Blue color component. The BGR configuration is output on LCDDATA [11:0] as shown in Figure 26-11 on page 1856. LCDDATA [23:12] are unused.

Figure 26-11. 12 bpp Color Component Ordering

1/2/4/8 bpp Data Format

The Palette frame buffer for 1/2/4/8 bpp data supports passive and active matrix displays. Active matrix is enabled by setting the T_{FT} bit in the **LCD Raster Control (LCDRASTRCTL)** register. When the T_{FTMAP} is set to 0, the output from the palette look-up is a 12 bpp BGR pixel as shown in Figure 26-4 on page 1852, where each color is a 4 bit value. This output is sent to LCDDATA [11:0]. By setting T_{FTMAP} to 1, the pixel data output is converted to a 16-bit BGR565 format. The extra least significant are dithered by replication of the component values' most significant bits. This conversion is shown in Figure 26-12 on page 1857.

Figure 26-12. 1/2/4/8 bpp Dither Output

26.3.7 Palette

As explained in the previous section, the pixel data is an index of palette entry (when palette is used). The number of colors supported is given by 2^{number of BPP}. However, due to a limitation of the grayscale/serializer block, fewer grayscales or colors may be supported.

The `PALMODE` field in the **LCD Raster Control (LCDRASTRCTL)** register affects the palette loading:

- If `PALMODE` is 0x0 (palette-plus-data mode) or 0x1 (palette-only mode), the palette is loaded by the DMA engine at the very beginning, which is followed by the loading of pixel data.
- If `PALMODE` is 0x2 (data-only mode), the palette is not loaded. Instead, the DMA engine loads the pixel data immediately.

26.3.8 Gray-Scaler/Serializer - Passive (STN) Mode

Once a palette entry is selected from the look-up palette by the pixel data, its content is sent to the grayscale/serializer. If it is monochrome data, it is encoded as 4 bits. If it is color data, it is encoded as 4 bits (Red), 4 bits (Green), and 4 bits (Blue). These 4-bit values are used to select one of the 16 intensity levels, as shown in Table 13-10. A patented algorithm is used during this processing to provide an optimized intensity value that matches the eye's visual perception of color/gray gradations.

26.3.9 Gray-Scaler/Serializer - Active (TFT) Mode

The gray-scaler/serializer is bypassed in this mode.

26.3.10 Color/Grayscale Intensities and Modulation Rates

The following table details the intensities and modulation rates for varying dither values.

Table 26-7. Intensities and Modulation Rates

| Dither Value (4-Bit Value from Palette) | Intensity (0% is White) | Modulation Rate (Ratio of ON to ON+OFF Pixels) |
|---|-------------------------|--|
| 0x0 | 0.0% | 0 |
| 0x1 | 14.3% | 1/7 |
| 0x2 | 20.0% | 1/5 |
| 0x3 | 25% | 1/4 |
| 0x4 | 33.3% | 3/9 |
| 0x5 | 40.0% | 2/5 |
| 0x6 | 44.4% | 4/9 |

Table 26-7. Intensities and Modulation Rates (continued)

| Dither Value (4-Bit Value from Palette) | Intensity (0% is White) | Modulation Rate (Ratio of ON to ON+OFF Pixels) |
|---|-------------------------|--|
| 0x7 | 50.0% | 1/2 |
| 0x8 | 55.6% | 5/9 |
| 0x9 | 60.0% | 3/5 |
| 0xA | 66.6% | 6/9 |
| 0xB | 75% | 3/4 |
| 0xC | 80.0% | 4/5 |
| 0xD | 85.7% | 6/7 |
| 0xE | 93.3% | 14/15 |
| 0xF | 100.0% | 1 |

26.3.11 Summary of Color Depth

summarizes the color depths depending on the number of BPP.

Table 26-8. Number of Colors/Shades of Gray Available on Screen

| Number of BPP | Passive Mode (LCDTFT = 0) | | Active Mode (LCDTFT = 1) |
|---------------|---|---|---|
| | Monochrome (LCDBW = 1) | Color (LCDBW = 0) | Color Only (LCDBW = 0) |
| 1 | 2 palette entries to select within 15 grayscales | 2 palette entries to select within 3375 possible colors | 2 palette entries to select within 4096 possible colors |
| 2 | 4 palette entries to select within 15 grayscales | 4 palette entries to select within 3375 possible colors | 4 palette entries to select within 4096 possible colors |
| 4 | 16 palette entries to select within 15 grayscales | 16 palette entries to select within 3375 possible colors | 16 palette entries to select within 4096 possible colors |
| 8 | Not relevant because it would consist in 256 palette entries to select within 15 grayscales, but exists anyways | 256 palette entries to select within 3375 possible colors | 256 palette entries to select within 4096 possible colors |
| 12 | X | 3375 possible colors | 4096 possible colors |
| 16 | X | 3375 possible colors (STN_565 = 1) | Up to 65536 possible colors |
| 24 | X | X | Up to 16.7 million colors |

26.3.12 Output Format

The following section describes the output format for both passive and active LCD modes.

26.3.12.1 Passive (STN) Mode

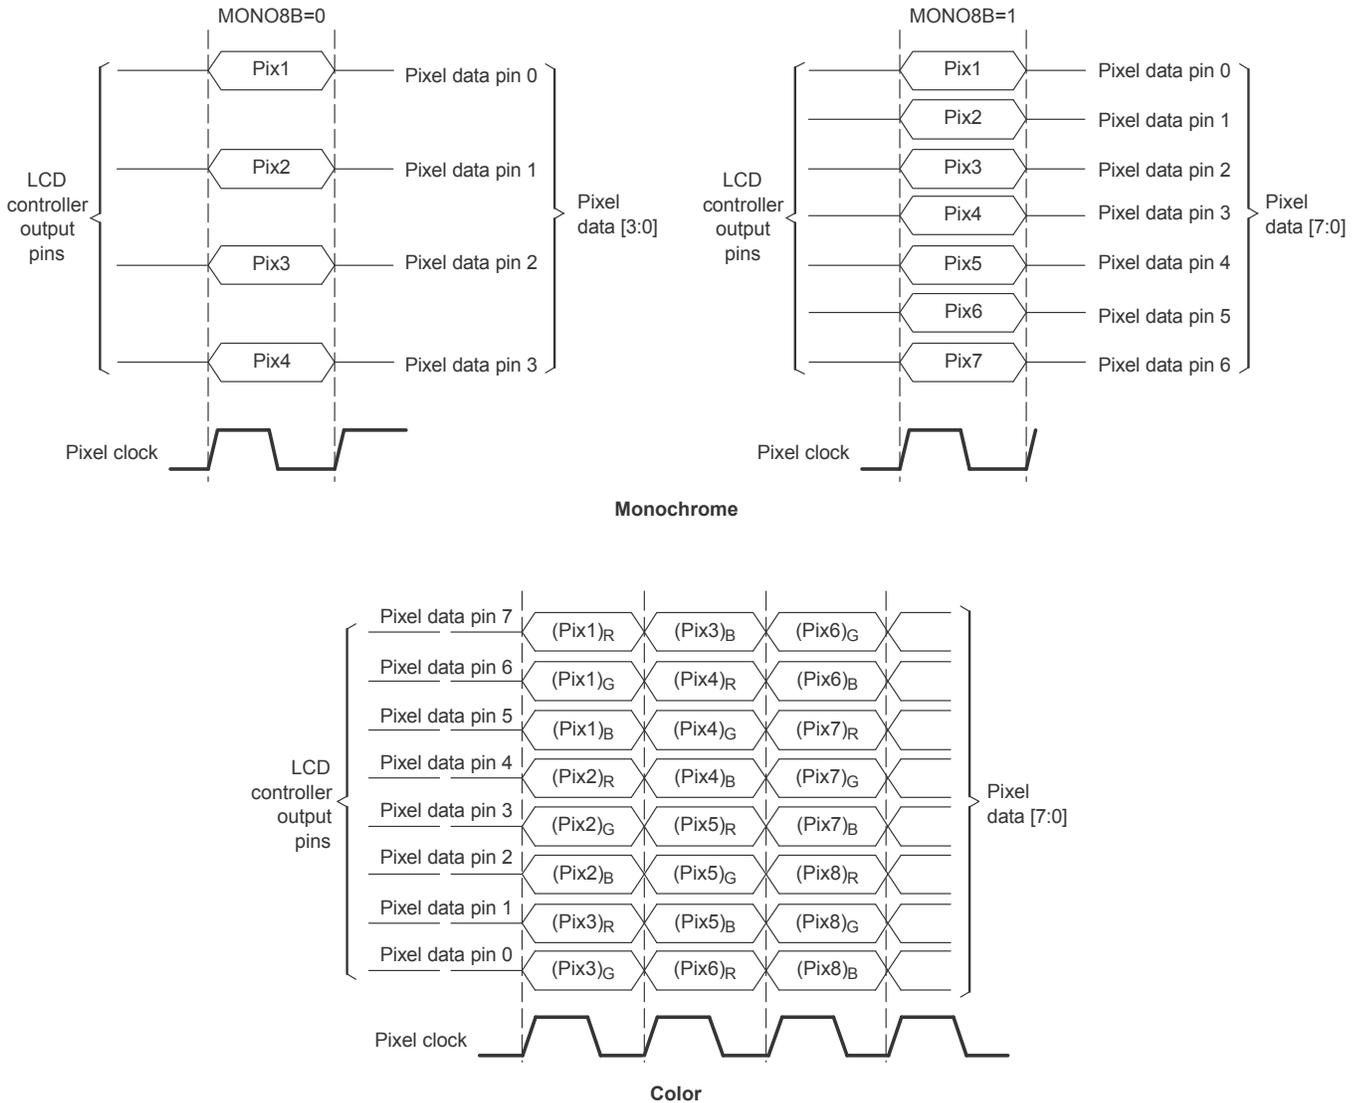

As shown in Figure 26-13 on page 1859, the pixel data stored in frame buffers go through palette (if applicable) and grayscale/serializer before reaching the Output FIFO. As a result, it is likely that the data fed to the output FIFO is numerically different from the data in the frame buffers. (However, they represent the same color or grayscale.)

The output FIFO formats the received data according to display modes (see Table 13-7). Figure 26-13 on page 1859, shows the actual data output on the external pins.

26.3.12.2 Active (TFT) Mode

As shown in Figure 26-13 on page 1859, the gray-scaler/serializer and output FIFO are bypassed in active (TFT) mode. Namely, at each pixel clock, one pixel data (16 bits) is output to the external LCD.

Figure 26-13. Monochrome and Color Output

26.3.13 Subpicture Feature

A feature exists in the LCD to cover either the top or lower portion of the display with a default color. This feature is called a subpicture and is illustrated in Figure 26-14 on page 1860. Subpictures are only allowed for Active Matrix Mode (when `LCDTFT = 0x1` in the **LCD Raster Control (LCDRASTRCTL)** register).

Subpicture reduce the bandwidth since lines containing default pixel data are not read from memory. For example, suppose the panel has 100 lines of which 50 are default pixel data lines. Then, only 50 lines of data are DMAed from DDR for this subpicture setup. That is, the **LCD DMA Frame Buffer**

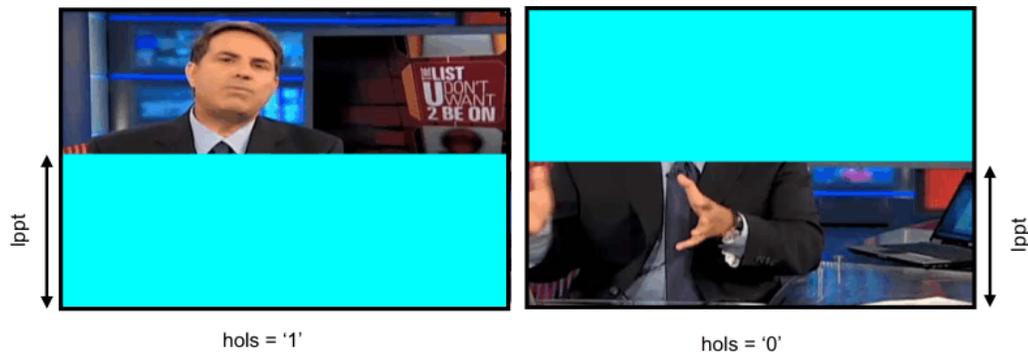

n Base Address (LCDDMABAFBn) and LCD DMA Frame Buffer n Base Address (LCDDMABAFBn) registers only encompass 50 lines of data instead of 100.

Figure 26-14. Example of Subpicture

The subpicture feature is enabled when the *SPEN* control bit in the **LCD Raster Subpanel Display n (LCDRASTRSUBPn)** register is set to 1. The *HOLS* bit, when programmed to 0, puts the Default Pixel Data lines at the top of the screen and the active video lines at the bottom of the screen. When the *HOLS* bit is set to 1, Active video lines are at the top of the screen and Default Pixel Data lines are at the bottom of the screen. The *HOLS* bit behavior is shown in Figure 26-15 on page 1860.

Figure 26-15. Subpicture Output with HOLS Bit Variations

The *LPPT* (lines per panel threshold) bitfield defines the number of lines at the bottom of the picture for both *HOLS* = 1 or 0. *LPPT* is an encoded value in the range {0:2047} used to represent the number of lines in the range {1:2048}.

26.4 Interrupts

The application can program the LCD controller to trigger an interrupt for the following events:

- DMA end-of-frame 1: The DMA end-of-frame 1 (*EOF1*) interrupt is triggered when the DMA module has completed transferring the contents of a bounded frame buffer 1.
- DMA end-of-frame 0: The DMA end-of-frame 0 (*EOF0*) interrupt is triggered when the DMA module has completed transferring the contents of a bounded frame buffer 0.

- **DMA palette loaded:** When `PALMODE` is set to Palette-only or Palette+data, the palette loaded interrupt is triggered when the palette portion of the DMA transfer has been stored in the Palette RAM.
- **DMA FIFO Underflow:** The FIFO Underflow (`FIFOU`) interrupt is triggered when the real-time output needs to send a value for pixel data but one cannot be found in the FIFO.
- **AC Bias Count Decrement to Zero:** For Passive Matrix displays, a count can be kept of the number of times the AC Bias line toggles. Once the specified number of transitions has been seen, the AC Bias Count (`ACBS`) interrupt is triggered. The module does not post any further interrupts or keep counting AC Bias transitions until the interrupt has been cleared.
- **Frame synchronization lost:** When the DMA module reads a frame buffer and stores it in the FIFO, it sets a start frame and an end frame indicator embedded with the data. On retrieving the data from the FIFO, the Sync Lost (`SYNCS`) interrupt is triggered if the start indicator is not found at the first pixel of a new frame.
- **Recurrent Raster mode frame done:** In raster mode, the Recurrent Frame Done (`RRASTRDONE`) interrupt is triggered each time a complete frame has been sent to the interface pins.
- **Raster or LIDD frame done (shared interrupt):** In LIDD DMA mode, a frame buffer of data is sent. When the frame buffer has completed, the LIDD Frame Done (`DONE`) interrupt is triggered. In order to do another LIDD DMA, the DMA engine must be disabled and then re-enabled.

In Raster mode, the interrupt is triggered after `LCDEN` bit is programmed to 0 in the **LCD Raster Control (LCDRASTRCTL)** register and after the last frame is sent to the pins. After the Raster mode DMA is running, the interrupt occurs only once after the module is disabled.

The interrupts are enabled in the **LCD Interrupt Mask register (LCDIM)** register. All pending interrupts in the LCD module must be serviced by the Host's Interrupt Service Routine before it exits.

26.5 Bus Transaction Modes

The LCD Controller supports character-based LCD panels by ensuring the bus cycles for reading/writing commands and data are met. The LIDD (LCD Interface Display Driver) provides this support. The LIDD interfaces with an ARM CPU in the SOC using a VBUS slave port. Abundant programmable timing parameters can be configured such that the off-chip interface can support a wide variety of character based LCD panels. Alternatively, the DMA module can be used to mimic the CPU and perform a sequence of write-only data bus transactions to the character based LCD panel. The Motorola and Intel interfaces support asynchronous and synchronous modes. The only difference between the two is that, for synchronous mode, the internal bus clock is output on a pin that replaces CS1. In other words, only one character panel can be supported under synchronous mode while two panels can be supported for asynchronous mode.

26.6 Initialization and Configuration

Basic configuration of the LCD controller is as follows:

1. Enable the LCD Controller in the System Control module using the **RCGCLCD** register. See page 419.
2. Enable the DMA, core and LIDD controller (if required) in the **LCDCCLKEN** register.

3. Select the LCD mode (LIDD or Raster) by programming the `LCDMODE` bit in the **LCDCCTL** register. In addition, configure the LCDCP or LCDMCLK frequency through the `CLKDIV` field.
4. When operating in LIDD mode:
 - a. Program the **LCDLIDDCTL** register along with the chip select configuration register, **LIDDCSnCFG**.
 - b. Select the DMA parameters in the **LCDDMACTL** register. Program the frame buffer boundaries in the **LCDDMABAFB0** and **LCDDMACAFB0** registers.
 - c. Enable any required interrupts in the **LCDIM** register.
 - d. Initiate LIDD mode transactions by setting the `DMAEN` bit in the **LCDLIDDCTL** register.
5. When operating in Raster Mode:
 - a. Program the **LCDRASTRCTL** register along with the raster timings in the **LCDRASTRTIMn** registers.
 - b. Configure the subpanel display in the **LCDRASTRSUBPn** registers.
 - c. Select the DMA parameters such as burst size, and memory layout in the **LCDDMACTL** register. Program the frame buffer boundaries in the **LCDDMABAFBn** and **LCDDMACAFBn** registers.
 - d. Enable any required interrupts in the **LCDIM** register.
 - e. Initiate Raster mode transactions by setting the `LCDEN` bit in the **LCDRASTRCTL** register.

The LCD DMA may interface to internal SRAM or the external memory through EPI for transfer of data. To configure the EPI for use with LCD, refer to “External Peripheral Interface (EPI)” on page 848.

Note: When using the LCD with EPI to interface to external memory, the external code address space 0x1000.0000 must be selected by programming the `ECADR` field to 0x1 in the **EPI Address Map (EPIADDRMAP)** register at EPI offset 0x01C.

26.7 Register Map

Table 26-9 on page 1862 lists the LCD registers. The offset listed is a hexadecimal increment to the register's address, relative to the LCD module's base address of 0x4405.0000.

Table 26-9. LCD Register Map

| Offset | Name | Type | Reset | Description | See page |
|--------|-------------|------|-------------|-------------------------------------|----------|
| 0x000 | LCDPID | RO | 0x4F20.1000 | LCD PID Register Format | 1864 |
| 0x004 | LCDCCTL | RW | 0x0000.0000 | LCD Control | 1865 |
| 0x00C | LCDLIDDCTL | RW | 0x0000.0000 | LCD LIDD Control | 1867 |
| 0x010 | LIDDCS0CFG | RW | 0x0044.0044 | LCD LIDD CS0 Configuration | 1870 |
| 0x014 | LIDDCS0ADDR | RW | 0x0000.0000 | LIDD CS0 Read/Write Address | 1871 |
| 0x018 | LIDDCS0DATA | RW | 0x0000.0000 | LIDD CS0 Data Read/Write Initiation | 1872 |

26.8 Register Descriptions

Following is a description of the individual registers of the LCD controller.

Register 1: LCD PID Register Format (LCDPID), offset 0x000

This register contains information regarding the Peripheral ID (PID) of the LCD module.

LCD PID Register Format (LCDPID)

Base 0x4405.0000

Offset 0x000

Type RO, reset 0x4F20.1000

| | | | | | | | | | | | | | | | | |
|-------|----------|----|----|----|-------|----|----|----|----------|----|----|----|-------|----|----|----|
| | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | reserved | | | | | | | | | | | | | | | |
| Type | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

| Type | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|-------|---|
| 31:11 | reserved | RO | 0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 10:8 | MAJOR | RO | 0x0 | Major Release Number This field contains the major release number for the IP. |
| 7:6 | reserved | RO | 0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 5:0 | MINOR | RO | 0x00 | Minor Release Number This field contains the minor release number for the IP. |

Register 2: LCD Control (LCDCTL), offset 0x004

The **LCD Control (LCDCTL)** register configures the mode, clock frequencies and restart behavior of the LCD Controller.

LCD Control (LCDCTL)

Base 0x4405.0000
Offset 0x004
Type RW, reset 0x0000.0000

| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|-----------|--|
| 31:10 | reserved | RO | 0x0000.00 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 9 | DMACS | RW | 0 | CS0/CS1 Select for LIDD DMA Writes Value Description 0 DMA writes to LIDD CS0 (LCDAC). 1 DMA writes to LIDD CS1 (LCDMCLK). Note: In Motorola 6800 or Intel 8080 synchronous modes, CS1 is not used and thus, DMACS should not be set to 0x1. |
| 8 | DMAEN | RW | 0 | LIDD DMA Enable Value Description 0 Deactivate DMA control of LIDD interface. DMA control is released upon completion of transfer of the current frame of data (LIDD Frame Done) when this bit is clear. The microcontroller has direct read/write access to the panel in this mode. 1 Activate DMA to drive LIDD interface to support streaming data to smart panels. The microcontroller cannot access the panel directly in this mode. |
| 7 | CS1E1 | RW | 0 | Chip Select 1 (CS1)/Enable 1(E1) Polarity Control CS1 is active low by default. EN1 is active high by default. Value Description 0 CS1/E1 (LCDMCLK) are not inverted. CS1 remains active low and E1 remains active high. 1 Invert CS1/E1 (LCDMCLK). CS1 is active high and E1 is active low. |

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|-------|---|
| 6 | CS0E0 | RW | 0 | <p>Chip Select 0 (CS0)/Enable 0 (E0) Polarity Control CS0 is active low by default. E0 is active high by default.</p> <p>Value Description</p> <p>0 CS0/E0 (<i>LCDAC</i>) are not inverted. CS0 remains active low and E0 remains active high.</p> <p>1 Invert CS0/E0. CS0 is active high and E0 is active low.</p> |
| 5 | WRDIRINV | RW | 0 | <p>Write Strobe (WR) /Direction (DIR) Polarity Control WR active low by default. DIR is write low/read high by default.</p> <p>Value Description</p> <p>0 WR/DIR (<i>LCDLP</i>) are not inverted. WR remains active low and DIR is write low/read high.</p> <p>1 Invert WR/DIR. WR is active high and DIR is write high/read low.</p> |
| 4 | RDEN | RW | 0 | <p>Read Strobe (RD) /Direct Enable (EN) Polarity Control RD is active low by default. EN is active high by default.</p> <p>Value Description</p> <p>0 RD/EN (<i>LCDCP</i>) are not inverted. RD is active low and EN is active high.</p> <p>1 Invert RD/EN (<i>LCDCP</i>). RD is active high and EN is active low.</p> |
| 3 | ALE | RW | 0 | <p>Address Latch Enable (ALE) Polarity Control ALE is active low by default.</p> <p>Value Description</p> <p>0 ALE (<i>LCDFP</i>) is not inverted.</p> <p>1 Invert ALE (<i>LCDFP</i>) . ALE is active high.</p> |
| 2:0 | MODE | RW | 0x0 | <p>LIDD Mode Select. Selects type of LCD display interface for the LIDD to drive. See Table 26-3 on page 1843 for external pin assignments based on <i>MODE</i> encoding.</p> <p>Value Description</p> <p>0x0 Synchronous Motorola 6800 Mode</p> <p>0x1 Asynchronous Motorola 6800 Mode</p> <p>0x2 Synchronous Intel 8080 mode</p> <p>0x3 Asynchronous Intel 8080 mode</p> <p>0x4 Asynchronous Hitachi mode</p> <p>0x5-0x7 reserved</p> |

The *MODE* bit field described above defines the function of the LCD external pins as follows:

Table 26-11. LCD Alternate Signal Functions in LIDD Mode

| PIN | MODE = 0x0 | MODE = 0x1 | MODE = 0x2 | MODE = 0x3 | MODE = 0x4 |
|---------|------------|------------|------------|------------|------------|
| LCDCP | RS/WS | RS/WS | RS | RS | N/A |
| LCDLP | DIR | DIR | WS | WS | DIR |
| LCDFP | ALE | ALE | ALE | ALE | ALE |
| LCDAC | CS0 | CS0 | CS0 | CS0 | E0 |
| LCDMCLK | MCLK | CS1 | MCLK | CS1 | E1 |

Register 4: LCD LIDD CS0 Configuration (LIDDCS0CFG), offset 0x010

The **LIDD CS0 Configuration (LIDDCS0CFG)** register defines the timings for the read and write strobes with respect to CS0.

LCD LIDD CS0 Configuration (LIDDCS0CFG)

Base 0x4405.0000
Offset 0x010
Type RW, reset 0x0044.0044

| | | | | | | | | | | | | | | | | |
|-------|------|----|----|----|-------|-------|----|----|----|----|--------|--------|----|----|-----|------|

| Bit/Field | Name | Type | Reset | Description |
|-----------|--------|------|-------|---|
| 31:27 | WRSU | RW | 0x0 | Write Strobe (WR) Set-Up Cycles When performing a write access, this field defines the number of MCLK cycles that the LCDDATA bus, output enable, ADE, DIR and CS0 signals have to be ready before the write strobe. The minimum value is 0x0. |
| 26:21 | WRDUR | RW | 0x2 | Write Strobe (WR) Duration Cycles This field value defines the number of MCLK cycles for which the write strobe is held active when performing a write access. The minimum value is 0x1. |
| 20:17 | WRHOLD | RW | 0x2 | Write Strobe (WR) Hold cycles. This field value defines the number of MCLK cycles for which the LCDDATA bus, output enable, ALE, DIR and CS0 signals are held after the write strobe is deasserted when performing a write access. The minimum value is 0x1. |
| 16:12 | RDSU | RW | 0x0 | Read Strobe (RD) Set-Up cycles. When performing a read access, this field defines the number of MCLK cycles that the LCDDATA bus, output enable, ALE, DIR and CS0 signals have to be ready before the read strobe is asserted. |
| 11:6 | RDDUR | RW | 0x1 | Read Strobe (RD) Duration cycles. This field defines the number of MCLK cycles for which the read strobe is held active when performing a read access. The minimum value is 0x1. |
| 5:2 | RDHOLD | RW | 0x1 | Read Strobe (RD) Hold cycles. This field defines of MCLK cycles for which the LCDDATA bus, output enable, ALE, DIR and CS0 signals are held after the read strobe is deasserted when performing a read access. The minimum value is 0x1. |
| 1:0 | GAP | RW | 0x0 | Field value defines the number of LCDMCLK cycles (GAP +1) between the end of one CS0 (LCDAC) device access and the start of another CS0 (LCDAC) device access unless the two accesses are both reads. In this case, this delay is not incurred. The minimum value is 0x0. |

Register 5: LIDD CS0 Read/Write Address (LIDDCS0ADDR), offset 0x014

This register contains the read and write address of the current access enabled by CS0 (LCDAC).

LIDD CS0 Read/Write Address (LIDDCS0ADDR)

Base 0x4405.0000
Offset 0x014
Type RW, reset 0x0000.0000

| | | | | | | | | | | | | | | | | |

| Bit/Field | Name | Type | Reset | Description |
|-----------|--------|------|-------|--|
| 31:27 | WRSU | RW | 0x0 | Write Strobe (WR) Set-Up Cycles When performing a write access, this field defines the number of L _{CDMCLK} cycles that Data Bus/Pad Output Enable, ALE, DIR, and CS1 have to be ready before WR (L _{CDLP}) is asserted. The minimum value is 0x0. |
| 26:21 | WRDUR | RW | 0x2 | Write Strobe (WR) Duration Cycles Field value defines the number of L _{CDMCLK} cycles for which WR (L _{CDLP}) is held active when performing a write access. The minimum value is 0x1. |
| 20:17 | WRHOLD | RW | 0x2 | Write Strobe (WR) Hold cycles. Field value defines the number of L _{CDMCLK} cycles for which Data Bus/Pad Output Enable, ALE, the DIR, and CS1 signals are held after WR (L _{CDLP}) is deasserted when performing a write access. The minimum value is 0x1. |
| 16:12 | RDSU | RW | 0x0 | Read Strobe (RD) Set-Up cycles. When performing a read access, this field defines the number of L _{CDMCLK} cycles that Data Bus/Pad Output Enable, ALE, the DIR, and CS1 signals have to be ready before RD (L _{CDCP}) is asserted. |
| 11:6 | RDDUR | RW | 0x1 | Read Strobe (RD) Duration cycles. Field value defines the number of L _{CDMCLK} cycles for which RD (L _{CDCP}) is held active when performing a read access. The minimum value is 0x1. |
| 5:2 | RDHOLD | RW | 0x1 | Read Strobe (RD) Hold cycles. Field value defines the number of L _{CDMCLK} cycles for which Data Bus/Pad Output Enable, ALE, DIR, and CS1 signals are held after RD (L _{CDCP}) is deasserted when performing a read access. The minimum value is 0x1. |
| 1:0 | GAP | RW | 0x0 | Field value defines the number of L _{CDMCLK} cycles (GAP + 1) between the end of one CS1 (L _{CDAC}) device access and the start of another CS0 (L _{CDAC}) device access unless the two accesses are both reads. In this case, this delay is not incurred. The minimum value is 0x0. |

Register 8: LIDD CS1 Address Read/Write Initiation (LIDDCS1ADDR), offset 0x020

This register contains the read and write address of the current access enabled by CS1 (LCDAC).

| 25 | TFT24 | RW | 0 | <p>24-Bit TFT Mode</p> <p>Value Description</p> <p>0 24-Bit TFT Mode disabled. Palette RAM lookup is used for output pixel data.</p> <p>1 24-Bit TFT Mode enabled. 24-bit data in TFT Active mode. The format of the framebuffer data depends on TFT24UPCK.</p> |
| 24 | FRMBUFSZ | RW | 0 | <p>Frame Buffer Select</p> <p>This mode is valid when LCDTFT is 0 and there are 16 bpp raw data frame buffers (bpp=00)</p> <p>Only for this case, this bit selects whether the frame buffer format is 16 bpp 565 or 12bpp.</p> <p>The Grayscale can only take 12 bits per pixel. The frame buffer data is 16 bits per pixel 565 when FRMBUFSZ is set to 1 and only the 4 most significant bits of each color component are sent to the Grayscale input.</p> <p>Value Description</p> <p>0 Framebuffer is 12 bpp packed in bits [11:0]</p> <p>1 Framebuffer is 16 bpp 565</p> |
| 23 | TFTMAP | RW | 0 | <p>TFT Mode Alternate Signal Mapping for Palettized Framebuffer</p> <p>This bit be 0 for all 12/16/24-bpp raw data formats. This bit can only be 1 for 1/2/4/8-bpp Palette Lookup data. Valid only in Active Matrix mode when LCDTFT=1.</p> <p>Value Description</p> <p>0 4 bits per component output data for 1, 2, 4, and 8 bpp modes will be right aligned on LCDDATA[11:0]</p> <p>1 4 bits per component output data for 1, 2, 4, and 8 bpp will be converted to 5,6,5, format and use LCDDATA[15:0]={R3 R2 R1 R0 R3 G3 G2 G1 G0 G3 G2 B3 B2 B1 B0 B3}</p> |
| 22 | NIBMODE | RW | 0 | <p>Nibble Mode</p> <p>This bit is used to determine palette indexing and is used in conjunction with RDORDER.</p> <p>Value Description</p> <p>0 Nibble mode is disabled</p> <p>1 Nibble mode is enabled</p> |
| 21:20 | PALMODE | RW | 0x0 | <p>Palette Loading Mode</p> <p>For Raw Data (12/16/24 bpp) frame buffers, no Palette lookup is employed. Thus, these frame buffers use the Data-Only loading mode.</p> <p>Value Description</p> <p>0x0 Palette and data loading, reset value</p> <p>0x1 Palette loading only</p> <p>0x2 Data loading only.</p> |

| Bit/Field | Name | Type | Reset | Description | | | | |
|-----------|--|------|-------|---|---|--|---|--|
| 19:12 | REQDLY | RW | 0x00 | <p>Palette Loading Delay</p> <p>This 8-bit parameter pauses reading of the Palette data from the asynchronous FIFO between each burst of 16 words. The delay is in terms of system clock (SYSCLK) cycles. The value (0-255) used to specify the number of system clock cycles that should be paused between bursts of 16 word reads from the asynchronous FIFO while loading the Palette SRAM. Programming REQDLY=0x00 disables this pause when loading the Palette table.</p> <p>When loading the Palette from system memory, palette data is burst into the internal Palette SRAM from the Asynchronous FIFO. 1, 2, and 4-bit per pixel frame buffer encodings use a fixed 16-word entry palette residing above the video data.</p> <p>The 8-bit per pixel frame buffer encoding uses a 256-word entry palette residing above the video data. Likewise, 12, 16, and 24-bit per pixel frame buffer encodings also define a 256-word entry palette even though these encodings will not do a full bit-depth palette lookup. However, the 256-word palette entry must still be read from DDR as a frame buffer is fetched.</p> <p>Bursting in 256 words in sequential SYSCLK cycles may cause the asynchronous FIFO to underflow depending on the DDR burst bandwidth.</p> | | | | |
| 11:10 | reserved | RO | 0x0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. | | | | |

Register 22: LCD Interrupt Raw Status and Set Register (LCDRISSET), offset 0x058

This register contains the raw interrupt status. In addition to providing the Raw Interrupt Status on a read, a 1 to a bit will set the associated interrupt.

LCD Interrupt Raw Status and Set Register (LCDRISSET)

Base 0x4405.0000

|-----------|----------|------|------------|---|
| 31:4 | reserved | RO | 0x0000.000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 3 | MAIN | RW | 0 | Software Reset for the entire LCD module. This reset affects the L3 clk and lcd_clk domain. Value Description 0 Reset Disabled 1 Reset Enabled |
| 2 | DMA | RW | 0 | Software Reset for the DMA submodule. This reset affects the L3 clk domain. Value Description 0 Reset Disabled 1 Reset Enabled |
| 1 | LIDD | RW | 0 | Software Reset for the LIDD submodule (character displays). This reset affects the LIDD logic in the lcd_clk domain. Value Description 0 Reset Disabled 1 Reset Enabled |
| 0 | CORE | RW | 0 | Software Reset for the Core, which encompasses the Raster Active Matrix and Passive Matrix logic. This reset affects the Core (active matrix and passive matrix raster mode) logic in the lcd_clk domain. Value Description 0 Reset Disabled 1 Reset Enabled |

27 Analog Comparators

An analog comparator is a peripheral that compares two analog voltages and provides a logical output that signals the comparison result.

Note: Not all comparators have the option to drive an output pin. See “Signal Description” on page 1910 for more information.

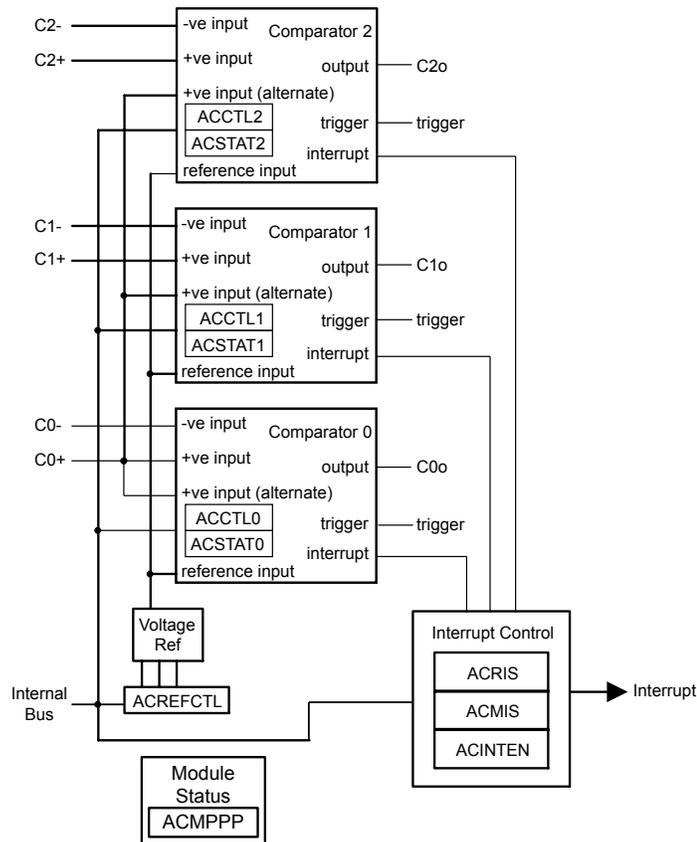

The comparator can provide its output to a device pin, acting as a replacement for an analog comparator on the board. In addition, the comparator can signal the application via interrupts or trigger the start of a sample sequence in the ADC. The interrupt generation and ADC triggering logic is separate and independent. This flexibility means, for example, that an interrupt can be generated on a rising edge and the ADC triggered on a falling edge.

The TM4C129XKCZAD microcontroller provides three independent integrated analog comparators with the following functions:

- Compare external pin input to external pin input or to internal programmable voltage reference
- Compare a test voltage against any one of the following voltages:
 - An individual external reference voltage
 - A shared single external reference voltage
 - A shared internal reference voltage

27.1 Block Diagram

Figure 27-1. Analog Comparator Module Block Diagram

Note: This block diagram depicts the maximum number of analog comparators and comparator outputs for the family of microcontrollers; the number for this specific device may vary. See page 1923 for what is included on this device.

27.2 Signal Description

The following table lists the external signals of the Analog Comparators and describes the function of each. The Analog Comparator output signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for the Analog Comparator signals. The `AFSEL` bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 803) should be set to choose the Analog Comparator function. The number in parentheses is the encoding that must be programmed into the `PMCn` field in the **GPIO Port Control (GPIOPCTL)** register (page 820) to assign the Analog Comparator signal to the specified GPIO port pin. The positive and negative input signals are configured by clearing the `DEN` bit in the **GPIO Digital Enable (GPIODEN)** register. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 772.

Table 27-1. Analog Comparators Signals (212BGA)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description |
|----------|------------|--------------------------|----------|-------------|-------------------------------------|
| C0+ | L2 | PC6 | I | Analog | Analog comparator 0 positive input. |

Table 27-1. Analog Comparators Signals (212BGA) (continued)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description |
|----------|------------|--------------------------|----------|-------------|-------------------------------------|
| C0- | K3 | PC7 | I | Analog | Analog comparator 0 negative input. |
| C0o | C2 G18 | PD0 (5) PL2 (5) | O | TTL | Analog comparator 0 output. |
| C1+ | M1 | PC5 | I | Analog | Analog comparator 1 positive input. |
| C1- | M2 | PC4 | I | Analog | Analog comparator 1 negative input. |
| C1o | C1 J18 | PD1 (5) PL3 (5) | O | TTL | Analog comparator 1 output. |
| C2+ | D6 | PP0 | I | Analog | Analog comparator 2 positive input. |
| C2- | D7 | PP1 | I | Analog | Analog comparator 2 negative input. |
| C2o | D2 | PD2 (5) | O | TTL | Analog comparator 2 output. |

27.3 Functional Description

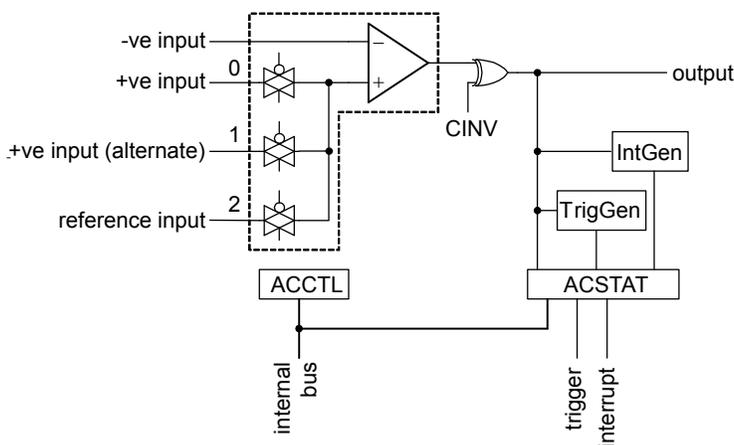

The comparator compares the VIN- and VIN+ inputs to produce an output, VOUT.

$$VIN- < VIN+, VOUT = 1$$

$$VIN- > VIN+, VOUT = 0$$

As shown in Figure 27-2 on page 1911, the input source for VIN- is an external input, Cn-, where n is the analog comparator number. In addition to an external input, Cn+, input sources for VIN+ can be the C0+ or an internal reference, V_{IREF}.

Figure 27-2. Structure of Comparator Unit

A comparator is configured through two status/control registers, **Analog Comparator Control (ACCTL)** and **Analog Comparator Status (ACSTAT)**. The internal reference is configured through one control register, **Analog Comparator Reference Voltage Control (ACREFCTL)**. Interrupt status and control are configured through three registers, **Analog Comparator Masked Interrupt Status (ACMIS)**, **Analog Comparator Raw Interrupt Status (ACRIS)**, and **Analog Comparator Interrupt Enable (ACINTEN)**.

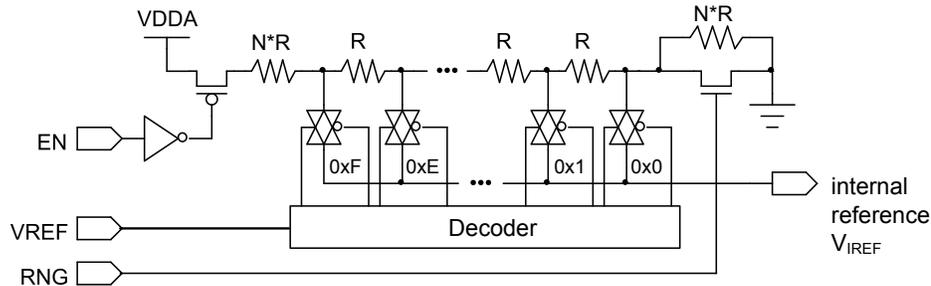

Typically, the comparator output is used internally to generate an interrupt as controlled by the I_{SEN} bit in the **ACCTL** register. The output may also be used to drive one of the external pins (C_{no}), or generate an analog-to-digital converter (ADC) trigger.

Important: The `ASRCP` bits in the `ACCTL` register must be set before using the analog comparators.

27.3.1 Internal Reference Programming

The structure of the internal reference is shown in Figure 27-3 on page 1912. The internal reference is controlled by a single configuration register (`ACREFCTL`).

Figure 27-3. Comparator Internal Reference Structure

Note: In the figure above, $N \cdot R$ represents a multiple of the R value that produces the results specified in Table 27-2 on page 1912.

The internal reference can be programmed in one of two modes (low range or high range) depending on the `RNG` bit in the `ACREFCTL` register. When `RNG` is clear, the internal reference is in high-range mode, and when `RNG` is set the internal reference is in low-range mode.

In each range, the internal reference, V_{IREF} , has 16 preprogrammed thresholds or step values. The threshold to be used to compare the external input voltage against is selected using the `VREF` field in the `ACREFCTL` register.

In the high-range mode, the V_{IREF} threshold voltages start at the ideal high-range starting voltage of $V_{DDA}/4.2$ and increase in ideal constant voltage steps of $V_{DDA}/29.4$.

In the low-range mode, the V_{IREF} threshold voltages start at 0 V and increase in ideal constant voltage steps of $V_{DDA}/22.12$. The ideal V_{IREF} step voltages for each mode and their dependence on the `RNG` and `VREF` fields are summarized in Table 27-2.

Table 27-2. Internal Reference Voltage and `ACREFCTL` Field Values

| ACREFCTL Register | | Output Reference Voltage Based on <code>VREF</code> Field Value |
|---------------------------|----------------------------|---|
| <code>EN</code> Bit Value | <code>RNG</code> Bit Value | |
| <code>EN=0</code> | <code>RNG=X</code> | 0 V (GND) for any value of <code>VREF</code> . It is recommended that <code>RNG=1</code> and <code>VREF=0</code> to minimize noise on the reference ground. |

Table 27-2. Internal Reference Voltage and ACREFACTL Field Values (continued)

| ACREFACTL Register | | Output Reference Voltage Based on VREF Field Value |
|--------------------|---------------|---|
| EN Bit Value | RNG Bit Value | |
| EN=1 | RNG=0 | <p>V_{IREF} High Range: 16 voltage threshold values indexed by VREF = 0x0 .. 0xF Ideal starting voltage (VREF=0): V_{DDA} / 4.2 Ideal step size: V_{DDA} / 29.4 Ideal V_{IREF} threshold values: V_{IREF} (VREF) = V_{DDA} / 4.2 + VREF * (V_{DDA} / 29.4), for VREF = 0x0 .. 0xF For minimum and maximum V_{IREF} threshold values, see Table 27-3 on page 1913.</p> |
| | RNG=1 | <p>V_{IREF} Low Range: 16 voltage threshold values indexed by VREF = 0x0 .. 0xF Ideal starting voltage (VREF=0): 0 V Ideal step size: V_{DDA} / 22.12 Ideal V_{IREF} threshold values: V_{IREF} (VREF) = VREF * (V_{DDA} / 22.12), for VREF = 0x0 .. 0xF For minimum and maximum V_{IREF} threshold values, see Table 27-4 on page 1914.</p> |

Note that the values shown in Table 27-2 are the ideal values of the V_{IREF} thresholds. These values actually vary between minimum and maximum values for each threshold step, depending on process and temperature. The minimum and maximum values for each step are given by:

- V_{IREF}(VREF) [Min] = Ideal V_{IREF}(VREF) – (Ideal Step size – 2 mV) / 2
- V_{IREF}(VREF) [Max] = Ideal V_{IREF}(VREF) + (Ideal Step size – 2 mV) / 2

Examples of minimum and maximum V_{IREF} values for V_{DDA} = 3.3V for high and low ranges, are shown in Table 27-3 and Table 27-4. Note that these examples are only valid for V_{DDA} = 3.3V; values scale up and down with V_{DDA}.

Table 27-3. Analog Comparator Voltage Reference Characteristics, V_{DDA} = 3.3V, EN= 1, and RNG = 0

| VREF Value | V _{IREF} Min | Ideal V _{IREF} | V _{IREF} Max | Unit |
|------------|-----------------------|-------------------------|-----------------------|------|
| 0x0 | 0.731 | 0.786 | 0.841 | V |

27.4 Initialization and Configuration

The following example shows how to configure an analog comparator to read back its output value from an internal register.

1. Enable the analog comparator clock by writing a value of 0x0000.0001 to the **RCGCACMP** register in the System Control module (see page 414).
2. Enable the clock to the appropriate GPIO modules via the **RCGCGPIO** register (see page 399). To find out which GPIO ports to enable, refer to Table 31-5 on page 2081.
3. In the GPIO module, enable the GPIO port/pin associated with the input signals as GPIO inputs. To determine which GPIO to configure, see Table 31-4 on page 2064.
4. Configure the **PMC_n** fields in the **GPIOPCTL** register to assign the analog comparator output signals to the appropriate pins (see page 820 and Table 31-5 on page 2081).
5. Configure the internal voltage reference to 1.65 V by writing the **ACREFCTL** register with the value 0x0000.030C.
6. Configure the comparator to use the internal voltage reference and to *not* invert the output by writing the **ACCTL_n** register with the value of 0x0000.040C.
7. Delay for 10 μ s.
8. Read the comparator output value by reading the **ACSTAT_n** register's **OVAL** value.

Change the level of the comparator negative input signal **C-** to see the **OVAL** value change.

27.5 Register Map

Table 27-5 on page 1915 lists the comparator registers. The offset listed is a hexadecimal increment to the register's address, relative to the Analog Comparator base address of 0x4003.C000. Note that the analog comparator clock must be enabled before the registers can be programmed (see page 414). There must be a delay of 3 system clocks after the analog comparator module clock is enabled before any analog comparator module registers are accessed.

Table 27-5. Analog Comparators Register Map

| Offset | Name | Type | Reset | Description | See page |
|--------|----------|------|-------------|---|----------|
| 0x000 | ACMIS | RW1C | 0x0000.0000 | Analog Comparator Masked Interrupt Status | 1916 |

27.6 Register Descriptions

The remainder of this section lists and describes the Analog Comparator registers, in numerical order by address offset.

Register 1: Analog Comparator Masked Interrupt Status (ACMIS), offset 0x000

This register provides a summary of the interrupt status (masked) of the comparators.

Analog Comparator Masked Interrupt Status (ACMIS)

Base 0x4003.C000
 Offset 0x000
 Type RW1C, reset 0x0000.0000

| | | | | | | | | | | | | | | | | |
|-------|----------|----|----|----|----|----|----|----|----|----|----|----|----|------|------|------|
| | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | reserved | | | | | | | | | | | | | | | |
| Type | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | reserved | | | | | | | | | | | | | IN2 | IN1 | IN0 |
| Type | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RW1C | RW1C | RW1C |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|------------|---|
| 31:3 | reserved | RO | 0x0000.000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 2 | IN2 | RW1C | 0 | <p>Comparator 2 Masked Interrupt Status</p> <p>Value Description</p> <p>0 No interrupt has occurred or the interrupt is masked.</p> <p>1 The IN2 bits in the ACRIS register and the ACINTEN registers are set, providing an interrupt to the interrupt controller.</p> <p>This bit is cleared by writing a 1. Clearing this bit also clears the IN2 bit in the ACRIS register.</p> |
| 1 | IN1 | RW1C | 0 | <p>Comparator 1 Masked Interrupt Status</p> <p>Value Description</p> <p>0 No interrupt has occurred or the interrupt is masked.</p> <p>1 The IN1 bits in the ACRIS register and the ACINTEN registers are set, providing an interrupt to the interrupt controller.</p> <p>This bit is cleared by writing a 1. Clearing this bit also clears the IN1 bit in the ACRIS register.</p> |
| 0 | IN0 | RW1C | 0 | <p>Comparator 0 Masked Interrupt Status</p> <p>Value Description</p> <p>0 No interrupt has occurred or the interrupt is masked.</p> <p>1 The IN0 bits in the ACRIS register and the ACINTEN registers are set, providing an interrupt to the interrupt controller.</p> <p>This bit is cleared by writing a 1. Clearing this bit also clears the IN0 bit in the ACRIS register.</p> |

Register 2: Analog Comparator Raw Interrupt Status (ACRIS), offset 0x004

This register provides a summary of the interrupt status (raw) of the comparators. The bits in this register must be enabled to generate interrupts using the **ACINTEN** register.

Analog Comparator Raw Interrupt Status (ACRIS)

Base 0x4003.C000

Offset 0x004

Type RO, reset 0x0000.0000

28 Pulse Width Modulator (PWM)

Pulse width modulation (PWM) is a powerful technique for digitally encoding analog signal levels. High-resolution counters are used to generate a square wave, and the duty cycle of the square wave is modulated to encode an analog signal. Typical applications include switching power supplies and motor control.

The TM4C129XKCZAD microcontroller contains one PWM module, with four PWM generator blocks and a control block, for a total of 8 PWM outputs. The control block determines the polarity of the PWM signals, and which signals are passed through to the pins.

Each PWM generator block produces two PWM signals that share the same timer and frequency and can either be programmed with independent actions or as a single pair of complementary signals with dead-band delays inserted. The output signals, `pwmA'` and `pwmB'`, of the PWM generation blocks are managed by the output control block before being passed to the device pins as `MnPWM0` and `MnPWM1` or `MnPWM2` and `MnPWM3`, and so on.

The TM4C129XKCZAD PWM module provides a great deal of flexibility and can generate simple PWM signals, such as those required by a simple charge pump as well as paired PWM signals with dead-band delays, such as those required by a half-H bridge driver. Three generator blocks can also generate the full six channels of gate controls required by a 3-phase inverter bridge.

Each PWM generator block has the following features:

- Four fault-condition handling inputs to quickly provide low-latency shutdown and prevent damage to the motor being controlled
- One 16-bit counter
 - Runs in Down or Up/Down mode
 - Output frequency controlled by a 16-bit load value
 - Load value updates can be synchronized
 - Produces output signals at zero and load value
- Two PWM comparators
 - Comparator value updates can be synchronized
 - Produces output signals on match
- PWM signal generator
 - Output PWM signal is constructed based on actions taken as a result of the counter and PWM comparator output signals
 - Produces two independent PWM signals
- Dead-band generator
 - Produces two PWM signals with programmable dead-band delays suitable for driving a half-H bridge
 - Can be bypassed, leaving input PWM signals unmodified

- Can initiate an ADC sample sequence

The control block determines the polarity of the PWM signals and which signals are passed through to the pins. The output of the PWM generation blocks are managed by the output control block before being passed to the device pins. The PWM control block has the following options:

- PWM output enable of each PWM signal
- Optional output inversion of each PWM signal (polarity control)
- Optional fault handling for each PWM signal
- Synchronization of timers in the PWM generator blocks
- Synchronization of timer/comparator updates across the PWM generator blocks
- Extended PWM synchronization of timer/comparator updates across the PWM generator blocks
- Interrupt status summary of the PWM generator blocks
- Extended PWM fault handling, with multiple fault signals, programmable polarities, and filtering
- PWM generators can be operated independently or synchronized with other generators

28.1 Block Diagram

Figure 28-1 on page 1927 provides the TM4C129XKCZAD PWM module diagram and Figure 28-2 on page 1927 provides a more detailed diagram of a TM4C129XKCZAD PWM generator. The TM4C129XKCZAD controller contains four generator blocks that generate eight independent PWM signals or four paired PWM signals with dead-band delays inserted.

Figure 28-1. PWM Module Diagram

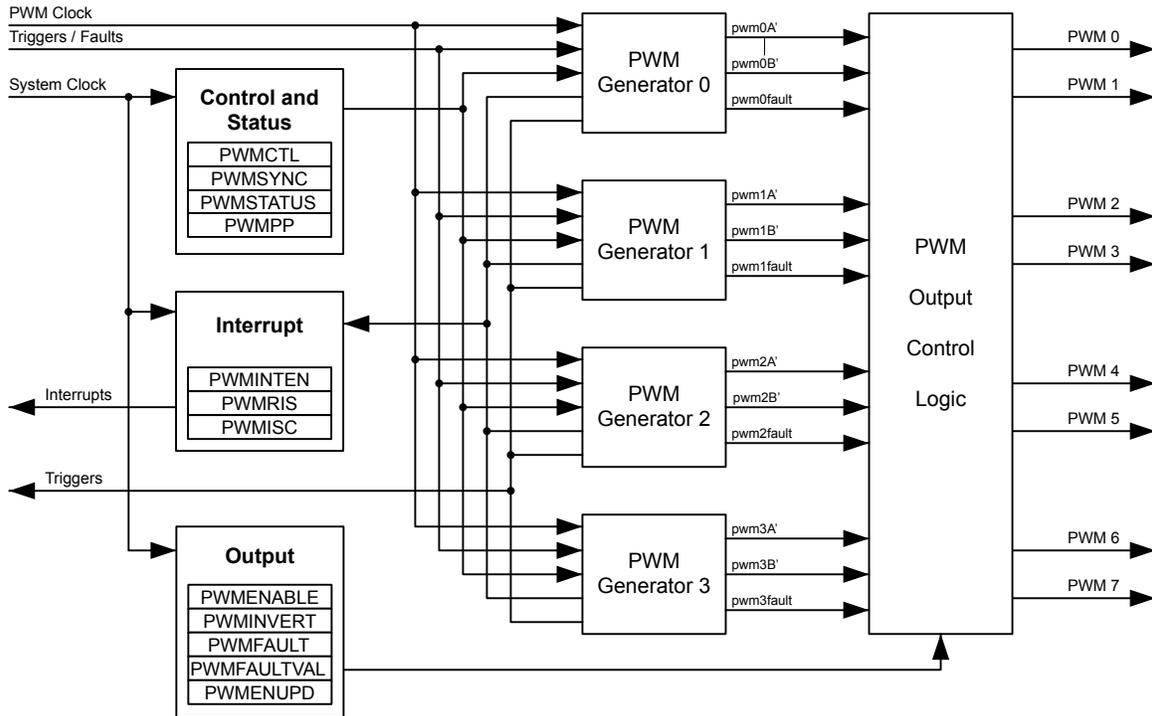

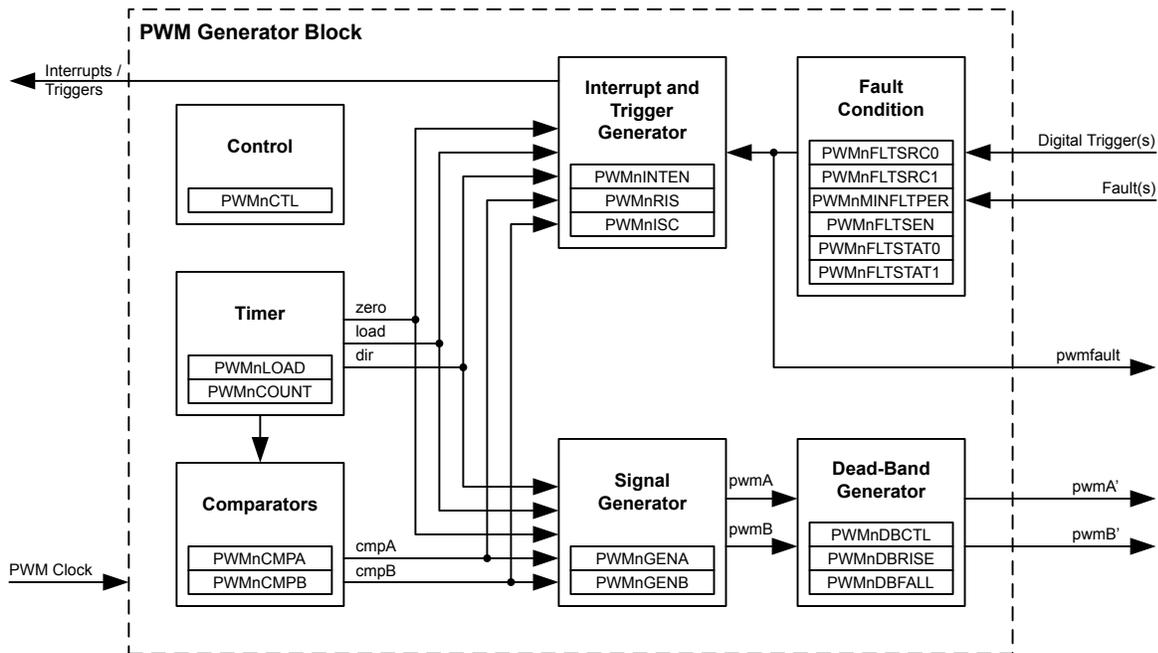

Figure 28-2. PWM Generator Block Diagram

28.2 Signal Description

The following table lists the external signals of the PWM module and describes the function of each. The PWM controller signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for these PWM signals. The `AFSEL` bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 803) should be set to choose the PWM function. The number in parentheses is the encoding that must be programmed into the `PMCn` field in the **GPIO Port Control (GPIOPTL)** register (page 820) to assign the PWM signal to the specified GPIO port pin. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 772.

Table 28-1. PWM Signals (212BGA)

28.3 Functional Description

28.3.1 Clock Configuration

The PWM has two clock source options:

- The System Clock
- A predivided System Clock

The clock source is selected by programming the `USEPWM` bit in the **PWM Clock Configuration (PWMCC)** register. The `PWMDIV` bitfield specifies the divisor of the System Clock that is used to create the PWM Clock.

28.3.2 PWM Timer

The timer in each PWM generator runs in one of two modes: Count-Down mode or Count-Up/Down mode. In Count-Down mode, the timer counts from the load value to zero, goes back to the load value, and continues counting down. In Count-Up/Down mode, the timer counts from zero up to the load value, back down to zero, back up to the load value, and so on. Generally, Count-Down mode is used for generating left- or right-aligned PWM signals, while the Count-Up/Down mode is used for generating center-aligned PWM signals.

The timers output three signals that are used in the PWM generation process: the direction signal (this is always Low in Count-Down mode, but alternates between Low and High in Count-Up/Down mode), a single-clock-cycle-width High pulse when the counter is zero, and a single-clock-cycle-width High pulse when the counter is equal to the load value. Note that in Count-Down mode, the zero pulse is immediately followed by the load pulse. In the figures in this chapter, these signals are labelled "dir," "zero," and "load."

28.3.3 PWM Comparators

Each PWM generator has two comparators that monitor the value of the counter; when either comparator matches the counter, they output a single-clock-cycle-width High pulse, labeled "cmpA" and "cmpB" in the figures in this chapter. When in Count-Up/Down mode, these comparators match both when counting up and when counting down, and thus are qualified by the counter direction signal. These qualified pulses are used in the PWM generation process. If either comparator match value is greater than the counter load value, then that comparator never outputs a High pulse.

Figure 28-3 on page 1930 shows the behavior of the counter and the relationship of these pulses when the counter is in Count-Down mode. Figure 28-4 on page 1930 shows the behavior of the counter and the relationship of these pulses when the counter is in Count-Up/Down mode. In these figures, the following definitions apply:

- LOAD is the value in the **PWMnLOAD** register
- COMPA is the value in the **PWMnCMPA** register
- COMPB is the value in the **PWMnCMPB** register
- 0 is the value zero
- load is the internal signal that has a single-clock-cycle-width High pulse when the counter is equal to the load value
- zero is the internal signal that has a single-clock-cycle-width High pulse when the counter is zero
- cmpA is the internal signal that has a single-clock-cycle-width High pulse when the counter is equal to **COMPA**
- cmpB is the internal signal that has a single-clock-cycle-width High pulse when the counter is equal to **COMPB**
- dir is the internal signal that indicates the count direction

Figure 28-3. PWM Count-Down Mode

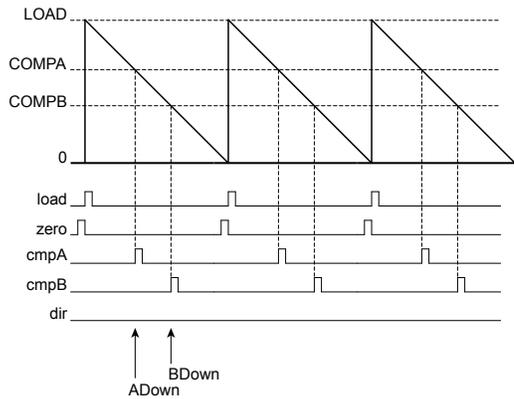

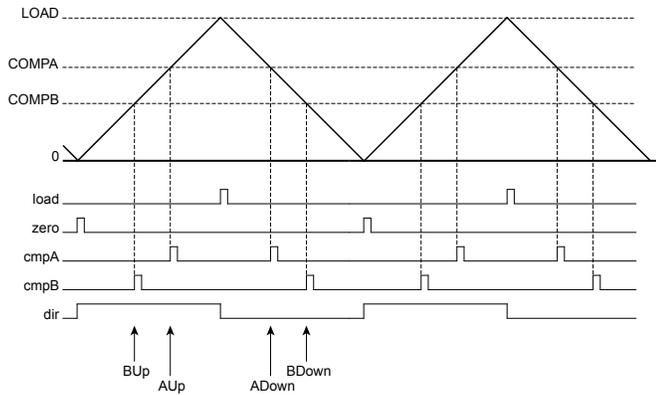

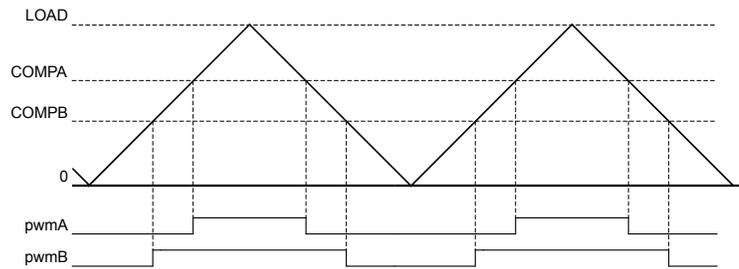

Figure 28-4. PWM Count-Up/Down Mode

28.3.4 PWM Signal Generator

Each PWM generator takes the load, zero, cmpA, and cmpB pulses (qualified by the dir signal) and generates two internal PWM signals, pwmA and pwmB. In Count-Down mode, there are four events that can affect these signals: zero, load, match A down, and match B down. In Count-Up/Down mode, there are six events that can affect these signals: zero, load, match A down, match A up, match B down, and match B up. The match A or match B events are ignored when they coincide with the zero or load events. If the match A and match B events coincide, the first signal, pwmA, is generated based only on the match A event, and the second signal, pwmB, is generated based only on the match B event.

For each event, the effect on each output PWM signal is programmable: it can be left alone (ignoring the event), it can be toggled, it can be driven Low, or it can be driven High. These actions can be used to generate a pair of PWM signals of various positions and duty cycles, which do or do not overlap. Figure 28-5 on page 1931 shows the use of Count-Up/Down mode to generate a pair of center-aligned, overlapped PWM signals that have different duty cycles. This figure shows the pwmA and pwmB signals before they have passed through the dead-band generator.

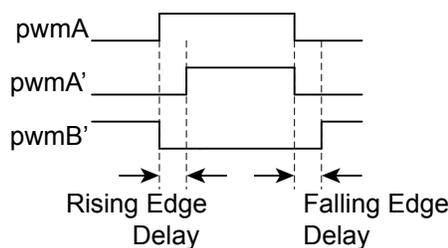

Figure 28-5. PWM Generation Example In Count-Up/Down Mode

In this example, the first generator is set to drive High on match A up, drive Low on match A down, and ignore the other four events. The second generator is set to drive High on match B up, drive Low on match B down, and ignore the other four events. Changing the value of comparator A changes the duty cycle of the pwmA signal, and changing the value of comparator B changes the duty cycle of the pwmB signal.

28.3.5 Dead-Band Generator

The pwmA and pwmB signals produced by each PWM generator are passed to the dead-band generator. If the dead-band generator is disabled, the PWM signals simply pass through to the pwmA' and pwmB' signals unmodified. If the dead-band generator is enabled, the pwmB signal is lost and two PWM signals are generated based on the pwmA signal. The first output PWM signal, pwmA' is the pwmA signal with the rising edge delayed by a programmable amount. The second output PWM signal, pwmB', is the inversion of the pwmA signal with a programmable delay added between the falling edge of the pwmA signal and the rising edge of the pwmB' signal.

The resulting signals are a pair of active High signals where one is always High, except for a programmable amount of time at transitions where both are Low. These signals are therefore suitable for driving a half-H bridge, with the dead-band delays preventing shoot-through current from damaging the power electronics. Figure 28-6 on page 1931 shows the effect of the dead-band generator on the pwmA signal and the resulting pwmA' and pwmB' signals that are transmitted to the output control block.

Figure 28-6. PWM Dead-Band Generator

28.3.6 Interrupt/ADC-Trigger Selector

Each PWM generator also takes the same four (or six) counter events and uses them to generate an interrupt or an ADC trigger. Any of these events or a set of these events can be selected as a source for an interrupt; when any of the selected events occur, an interrupt is generated. Additionally, the same event, a different event, the same set of events, or a different set of events can be selected as a source for an ADC trigger; when any of these selected events occur, an ADC trigger pulse is generated. The selection of events allows the interrupt or ADC trigger to occur at a specific position

within the pwmA or pwmB signal. Note that interrupts and ADC triggers are based on the raw events; delays in the PWM signal edges caused by the dead-band generator are not taken into account.

28.3.7 Synchronization Methods

The PWM module provides four PWM generators, each providing two PWM outputs that may be used in a wide variety of applications. Generally speaking, the PWM is used in one of two categories of operation:

- **Unsynchronized.** The PWM generator and its two output signals are used alone, independent of other PWM generators.
- **Synchronized.** The PWM generator and its two outputs signals are used in conjunction with other PWM generators using a common, unified time base. If multiple PWM generators are configured with the same counter load value, synchronization can be used to guarantee that they also have the same count value (the PWM generators must be configured before they are synchronized). With this feature, more than two $MnPWMn$ signals can be produced with a known relationship between the edges of those signals because the counters always have the same values. Other states in the module provide mechanisms to maintain the common time base and mutual synchronization.

The counter in a PWM generator can be reset to zero by writing the **PWM Time Base Sync (PWMSYNC)** register and setting the $SYNCn$ bit associated with the generator. Multiple PWM generators can be synchronized together by setting all necessary $SYNCn$ bits in one access. For example, setting the $SYNC0$ and $SYNC1$ bits in the **PWMSYNC** register causes the counters in PWM generators 0 and 1 to reset together.

Additional synchronization can occur between multiple PWM generators by updating register contents in one of the following three ways:

- **Immediately.** The write value has immediate effect, and the hardware reacts immediately.
- **Locally Synchronized.** The write value does not affect the logic until the counter reaches the value zero at the end of the PWM cycle. In this case, the effect of the write is deferred, providing a guaranteed defined behavior and preventing overly short or overly long output PWM pulses.
- **Globally Synchronized.** The write value does not affect the logic until two sequential events have occurred: (1) the Update mode for the generator function is programmed for global synchronization in the **PWMnCTL** register, and (2) the counter reaches zero at the end of the PWM cycle. In this case, the effect of the write is deferred until the end of the PWM cycle following the end of all updates. This mode allows multiple items in multiple PWM generators to be updated simultaneously without odd effects during the update; everything runs from the old values until a point at which they all run from the new values. The Update mode of the load and comparator match values can be individually configured in each PWM generator block. It typically makes sense to use the synchronous update mechanism across PWM generator blocks when the timers in those blocks are synchronized, although this is not required in order for this mechanism to function properly.

The following registers provide either local or global synchronization based on the state of various Update mode bits and fields in the **PWMnCTL** register ($LOADUPD$; $CMPAUPD$; $CMPBUPD$):

- Generator Registers: **PWMnLOAD**, **PWMnCMPA**, and **PWMnCMPB**

The following registers default to immediate update, but are provided with the optional functionality of synchronously updating rather than having all updates take immediate effect:

- Module-Level Register: **PWMENABLE** (based on the state of the `ENUPDn` bits in the `PWMENUPD` register).
- Generator Register: **PWMnGENA**, **PWMnGENB**, **PWMnDBCTL**, **PWMnDBRISE**, and **PWMnDBFALL** (based on the state of various Update mode bits and fields in the **PWMnCTL** register (`GENAUPD`; `GENBUPD`; `DBCTLUPD`; `DBRISEUPD`; `DBFALLUPD`)).

All other registers are considered statically provisioned for the execution of an application or are used dynamically for purposes unrelated to maintaining synchronization and therefore do not need synchronous update functionality.

28.3.8 Fault Conditions

A fault condition is one in which the controller must be signaled to stop normal PWM function and then set the `MnPWMn` signals to a safe state. Two basic situations cause fault conditions:

- The microcontroller is stalled and cannot perform the necessary computation in the time required for motion control
- An external error or event is detected

The PWM generator can use the following inputs to generate a fault condition, including:

- `MnFAULTn` pin assertion
- A stall of the controller generated by the debugger
- The trigger of an ADC digital comparator

Fault conditions are calculated on a per-PWM generator basis. Each PWM generator configures the necessary conditions to indicate a fault condition exists. This method allows the development of applications with dependent and independent control.

Four fault input pins (`MnFAULTn`) are available. These inputs may be used with circuits that generate an active High or active Low signal to indicate an error condition. A `MnFAULTn` pins may be individually programmed for the appropriate logic sense using the **PWMnFLTSEN** register.

The PWM generator's mode control, including fault condition handling, is provided in the **PWMnCTL** register. This register determines whether the input or a combination of `MnFAULTn` input signals and/or digital comparator triggers (as configured by the **PWMnFLTSRC0** and **PWMnFLTSRC1** registers) is used to generate a fault condition. The **PWMnCTL** register also selects whether the fault condition is maintained as long as the external condition lasts or if it is latched until the fault condition until cleared by software. Finally, this register also enables a counter that may be used to extend the period of a fault condition for external events to assure that the duration is a minimum length. The minimum fault period count is specified in the **PWMnMINFLTPER** register.

Note: When using an ADC digital comparator as a fault source, the `LATCH` and `MINFLTPER` bits in the **PWMnCTL** register should be set to 1 to ensure trigger assertions are captured.

Status regarding the specific fault cause is provided in the **PWMnFLTSTAT0** and **PWMnFLTSTAT1** registers. Note that the fault status registers, **PWMnFLTSTAT0** and **PWMnFLTSTAT1**, reflect the status of all fault sources, regardless of what fault sources are enabled for that particular generator.

PWM generator fault conditions may be promoted to a controller interrupt using the **PWMINTEN** register.

28.3.9 Output Control Block

The output control block takes care of the final conditioning of the `pwmA'` and `pwmB'` signals before they go to the pins as the `MnPWMn` signals. Via a single register, the **PWM Output Enable (PWENABLE)** register, the set of PWM signals that are actually enabled to the pins can be modified. This function can be used, for example, to perform commutation of a brushless DC motor with a single register write (and without modifying the individual PWM generators, which are modified by the feedback control loop). In addition, the updating of the bits in the **PWMENABLE** register can be configured to be immediate or locally or globally synchronized to the next synchronous update using the **PWM Enable Update (PWMENUUPD)** register.

During fault conditions, the PWM output signals, `MnPWMn`, usually must be driven to safe values so that external equipment may be safely controlled. The **PWMFAULT** register specifies whether during a fault condition, the generated signal continues to be passed driven or to an encoding specified in the **PWMFAULTVAL** register.

A final inversion can be applied to any of the `MnPWMn` signals, making them active Low instead of the default active High using the **PWM Output Inversion (PWMINVERT)**. The inversion is applied even if a value has been enabled in the **PWMFAULT** register and specified in the **PWMFAULTVAL** register. In other words, if a bit is set in the **PWMFAULT**, **PWMFAULTVAL**, and **PWMINVERT** registers, the output on the `MnPWMn` signal is 0, not 1 as specified in the **PWMFAULTVAL** register.

28.4 Initialization and Configuration

The following example shows how to initialize PWM Generator 0 with a 25-kHz frequency, a 25% duty cycle on the `MnPWM0` pin, and a 75% duty cycle on the `MnPWM1` pin. This example assumes the system clock is 20 MHz.

1. Enable the PWM clock by setting its corresponding bit in the **RCGCPWM** register in the System Control module (see page 415).
2. Enable the clock to the appropriate GPIO module via the **RCGCGPIO** register in the System Control module (see page 399).
3. In the GPIO module, enable the appropriate pins for their alternate function using the **GPIOAFSEL** register. To determine which GPIOs to configure, see Table 31-4 on page 2064.
4. Configure the `PMCn` fields in the **GPIOPCTL** register to assign the PWM signals to the appropriate pins (see page 820 and Table 31-5 on page 2081).
5. Configure the **PWM Clock Configuration (PWMCC)** register to use the PWM divide (`USEPWMDIV`) and set the divider (`PWMDIV`) to divide by 2 (`0x0`).
6. Configure the PWM generator for countdown mode with immediate updates to the parameters.
 - Write the **PWM0CTL** register with a value of `0x0000.0000`.
 - Write the **PWM0GENA** register with a value of `0x0000.008C`.
 - Write the **PWM0GENB** register with a value of `0x0000.080C`.
7. Set the period. For a 25-KHz frequency, the period = $1/25,000$, or 40 microseconds. The PWM clock source is 10 MHz; the system clock divided by 2. Thus there are 400 clock ticks per period. Use this value to set the **PWM0LOAD** register. In Count-Down mode, set the `LOAD` field in the **PWM0LOAD** register to the requested period minus one.

- Write the **PWM0LOAD** register with a value of 0x0000.018F.
8. Set the pulse width of the M_n PWM0 pin for a 25% duty cycle.
 - Write the **PWM0CMPA** register with a value of 0x0000.012B.
 9. Set the pulse width of the M_n PWM1 pin for a 75% duty cycle.
 - Write the **PWM0CMPB** register with a value of 0x0000.0063.
 10. Start the timers in PWM generator 0.
 - Write the **PWM0CTL** register with a value of 0x0000.0001.
 11. Enable PWM outputs.
 - Write the **PWMENABLE** register with a value of 0x0000.0003.

28.5 Register Map

Table 28-2 on page 1935 lists the PWM registers. The offset listed is a hexadecimal increment to the register's address, relative to the PWM module's base address:

- PWM0: 0x4002.8000

Note that the PWM module clock must be enabled before the registers can be programmed. There must be a delay of 3 system clocks after the PWM module clock is enabled before any PWM module registers are accessed.

Table 28-2. PWM Register Map

| Offset | Name | Type | Reset | Description | See page |
|--------|-------------|------|-------------|-----------------------------------|----------|
| 0x000 | PWMCTL | RW | 0x0000.0000 | PWM Master Control | 1939 |

28.6 Register Descriptions

The remainder of this section lists and describes the PWM registers, in numerical order by address offset.

Register 1: PWM Master Control (PWMCTL), offset 0x000

This register provides master control over the PWM generation blocks.

PWM Master Control (PWMCTL)

PWM0 base: 0x4002.8000

Offset 0x000

Type RW, reset 0x0000.0000

| | | | | | | | | | | | | | | | | | |
|-------|----------|----|----|----|----|----|----|----|----|----|----|----|-------------|-------------|-------------|-------------|----|
| | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | |

| 1 | GLOBALSYNC1 | RW | 0 | <p>Update PWM Generator 1</p> <p>Value Description</p> <p>0 No effect.</p> <p>1 Any queued update to a load or comparator register in PWM generator 1 is applied the next time the corresponding counter becomes zero.</p> <p>This bit automatically clears when the updates have completed; it cannot be cleared by software.</p> |
| 0 | GLOBALSYNC0 | RW | 0 | <p>Update PWM Generator 0</p> <p>Value Description</p> <p>0 No effect.</p> <p>1 Any queued update to a load or comparator register in PWM generator 0 is applied the next time the corresponding counter becomes zero.</p> <p>This bit automatically clears when the updates have completed; it cannot be cleared by software.</p> |

Register 2: PWM Time Base Sync (PWMSYNC), offset 0x004

This register provides a method to perform synchronization of the counters in the PWM generation blocks. Setting a bit in this register causes the specified counter to reset back to 0; setting multiple bits resets multiple counters simultaneously. The bits auto-clear after the reset has occurred; reading them back as zero indicates that the synchronization has completed.

PWM Time Base Sync (PWMSYNC)

PWM0 base: 0x4002.8000

Offset 0x004

Type RW, reset 0x0000.0000

| | | | | | | | | | | | | | | | | | |

|-----------|----------|------|------------|---|
| 31:4 | reserved | RO | 0x0000.000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 3 | SYNC3 | RW | 0 | Reset Generator 3 Counter Value Description 0 No effect. 1 Resets the PWM generator 3 counter. |
| 2 | SYNC2 | RW | 0 | Reset Generator 2 Counter Value Description 0 No effect. 1 Resets the PWM generator 2 counter. |
| 1 | SYNC1 | RW | 0 | Reset Generator 1 Counter Value Description 0 No effect. 1 Resets the PWM generator 1 counter. |
| 0 | SYNC0 | RW | 0 | Reset Generator 0 Counter Value Description 0 No effect. 1 Resets the PWM generator 0 counter. |

Register 3: PWM Output Enable (PWMENABLE), offset 0x008

This register provides a master control of which generated pwmA' and pwmB' signals are output to the M_nPWM_n pins. By disabling a PWM output, the generation process can continue (for example, when the time bases are synchronized) without driving PWM signals to the pins. When bits in this register are set, the corresponding pwmA' or pwmB' signal is passed through to the output stage. When bits are clear, the pwmA' or pwmB' signal is replaced by a zero value which is also passed to the output stage. The **PWMINVERT** register controls the output stage, so if the corresponding bit is set in that register, the value seen on the M_nPWM_n signal is inverted from what is configured by the bits in this register. Updates to the bits in this register can be immediate or locally or globally synchronized to the next synchronous update as controlled by the $ENUPD_n$ fields in the **PWMENUPD** register.

PWM Output Enable (PWMENABLE)

PWM0 base: 0x4002.8000
 Offset 0x008
 Type RW, reset 0x0000.0000

Register 4: PWM Output Inversion (PWMINVERT), offset 0x00C

This register provides a master control of the polarity of the M_nPWM_n signals on the device pins. The $pwmA'$ and $pwmB'$ signals generated by the PWM generator are active High; but can be made active Low via this register. Disabled PWM channels are also passed through the output inverter (if so configured) so that inactive signals can be High. In addition, if the **PWMFAULT** register enables a specific value to be placed on the M_nPWM_n signals during a fault condition, that value is inverted if the corresponding bit in this register is set.

Register 5: PWM Output Fault (PWMFAULT), offset 0x010

This register controls the behavior of the M_nPWM_n outputs in the presence of fault conditions. Both the fault inputs (M_nFAULT_n pins and digital comparator outputs) and debug events are considered fault conditions. On a fault condition, each pwmA' or pwmB' signal can be passed through unmodified or driven to the value specified by the corresponding bit in the **PWMFAULTVAL** register. For outputs that are configured for pass-through, the debug event handling on the corresponding PWM generator also determines if the pwmA' or pwmB' signal continues to be generated.

Fault condition control occurs before the output inverter, so PWM signals driven to a specified value on fault are inverted if the channel is configured for inversion (therefore, the pin is driven to the logical complement of the specified value on a fault condition).

Register 6: PWM Interrupt Enable (PWMINTEN), offset 0x014

This register controls the global interrupt generation capabilities of the PWM module. The events that can cause an interrupt are the fault input and the individual interrupts from the PWM generators.

Note: The "n" in the INTFAULT_n and INTPWM_n bits in this register correspond to the PWM generators, not to the FAULT_n signals.

Register 7: PWM Raw Interrupt Status (PWMRIS), offset 0x018

This register provides the current set of interrupt sources that are asserted, regardless of whether they are enabled to cause an interrupt to be asserted to the interrupt controller. The fault interrupt is asserted based on the fault condition source that is specified by the **PWMnCTL**, **PWMnFLTSRC0** and **PWMnFLTSRC1** registers. The fault interrupt is latched on detection and must be cleared through the **PWM Interrupt Status and Clear (PWMISC)** register. The actual value of the $M_nFAULTn$ signals can be observed using the **PWMSTATUS** register.

The PWM generator interrupts simply reflect the status of the PWM generators and are cleared via the interrupt status register in the PWM generator blocks. If a bit is set, the event is active; if a bit is clear the event is not active.

|-----------|---------|------|-------|-------------------------|
| 0 | INTPWM0 | RO | 0 | PWM0 Interrupt Asserted |

Value Description

0 The PWM generator 0 block interrupt has not been asserted.

1 The PWM generator 0 block interrupt is asserted.

The **PWM0RIS** register shows the source of this interrupt. This bit is cleared by writing a 1 to the corresponding bit in the **PWM0ISC** register.

Register 8: PWM Interrupt Status and Clear (PWMISC), offset 0x01C

This register provides a summary of the interrupt status of the individual PWM generator blocks. If a fault interrupt is set, the corresponding M_nFAULT_n input has caused an interrupt. For the fault interrupt, a write of 1 to that bit position clears the latched interrupt status. If an block interrupt bit is set, the corresponding generator block is asserting an interrupt. The individual interrupt status registers, **PWMnISC**, in each block must be consulted to determine the reason for the interrupt and used to clear the interrupt.

| | | | | 0 The PWM generator 0 block interrupt is not asserted or is not enabled. |
| | | | | 1 An enabled interrupt for the PWM generator 0 block is asserted. |
| | | | | The PWM0RIS register shows the source of this interrupt. This bit is cleared by writing a 1 to the corresponding bit in the PWM0ISC register. |

Register 9: PWM Status (PWMSTATUS), offset 0x020

This register provides the unlatched status of the PWM generator fault condition.

PWM Status (PWMSTATUS)

PWM0 base: 0x4002.8000

Offset 0x020

Type RO, reset 0x0000.0000

| | | | | Value Description |
| | | | | 0 The fault condition for PWM generator 0 is not asserted. |
| | | | | 1 The fault condition for PWM generator 0 is asserted. If the <code>FLTSRC</code> bit in the <code>PWM0CTL</code> register is clear, the input is the source of the fault condition, and is therefore asserted. |

Register 10: PWM Fault Condition Value (PWMFAULTVAL), offset 0x024

This register specifies the output value driven on the M_nPWM_n signals during a fault condition if enabled by the corresponding bit in the **PWMFAULT** register. Note that if the corresponding bit in the **PWMINVERT** register is set, the output value is driven to the logical NOT of the bit value in this register.

PWM Fault Condition Value (PWMFAULTVAL)

Register 11: PWM Enable Update (PWMENUPD), offset 0x028

This register specifies when updates to the PWM_nEN bit in the **PWMENABLE** register are performed. The PWM_nEN bit enables the pwmA' or pwmB' output to be passed to the microcontroller's pin. Updates can be immediate or locally or globally synchronized to the next synchronous update.

PWM Enable Update (PWMENUPD)

Register 12: PWM0 Control (PWM0CTL), offset 0x040

Register 13: PWM1 Control (PWM1CTL), offset 0x080

Register 14: PWM2 Control (PWM2CTL), offset 0x0C0

Register 15: PWM3 Control (PWM3CTL), offset 0x100

These registers configure the PWM signal generation blocks (PWM0CTL controls the PWM generator 0 block, and so on). The Register Update mode, Debug mode, Counting mode, and Block Enable mode are all controlled via these registers. The blocks produce the PWM signals, which can be either two independent PWM signals (from the same counter), or a paired set of PWM signals with dead-band delays added.

The PWM0 block produces the M_n PWM0 and M_n PWM1 outputs, the PWM1 block produces the M_n PWM2 and M_n PWM3 outputs, the PWM2 block produces the M_n PWM4 and M_n PWM5 outputs, and the PWM3 block produces the M_n PWM6 and M_n PWM7 outputs.

| 18 | LATCH | RW | 0 | Latch Fault Input |
| | | | | Value Description |
| | | | 0 | Fault Condition Not Latched A fault condition is in effect for as long as the generating source is asserting. |
| | | | 1 | Fault Condition Latched A fault condition is set as the result of the assertion of the faulting source and is held (latched) while the PWMISC INTFAULTn bit is set. Clearing the INTFAULTn bit clears the fault condition. |
| | Note: | | | When using an ADC digital comparator as a fault source, the LATCH and MINFLTPER bits in the PWMnCTL register should be set to 1 to ensure trigger assertions are captured. |

| Bit/Field | Name | Type | Reset | Description |
|-----------|-----------|------|-------|--|
| 17 | MINFLTPER | RW | 0 | <p>Minimum Fault Period</p> <p>This bit specifies that the PWM generator enables a one-shot counter to provide a minimum fault condition period.</p> <p>The timer begins counting on the rising edge of the fault condition to extend the condition for a minimum duration of the count value. The timer ignores the state of the fault condition while counting.</p> <p>The minimum fault delay is in effect only when the MINFLTPER bit is set. If a detected fault is in the process of being extended when the MINFLTPER bit is cleared, the fault condition extension is aborted.</p> <p>The delay time is specified by the PWMnMINFLTPER register MFP field value. The effect of this is to pulse stretch the fault condition input.</p> <p>The delay value is defined by the PWM clock period. Because the fault input is not synchronized to the PWM clock, the period of the time is $PWMClock * (MFP\ value + 1)$ or $PWMClock * (MFP\ value + 2)$.</p> <p>The delay function makes sense only if the fault source is unlatched. A latched fault source makes the fault condition appear asserted until cleared by software and negates the utility of the extend feature. It applies to all fault condition sources as specified in the FLTSRC field.</p> <p>Value Description</p> <p>0 The FAULT input deassertion is unaffected.</p> <p>1 The PWMnMINFLTPER one-shot counter is active and extends the period of the fault condition to a minimum period.</p> <p>Note: When using an ADC digital comparator as a fault source, the LATCH and MINFLTPER bits in the PWMnCTL register should be set to 1 to ensure trigger assertions are captured.</p> |

| Bit/Field | Name | Type | Reset | Description |
|--|--------|------|-------|--|
| 2 | DEBUG | RW | 0 | Debug Mode |
| | | | | Value Description |
| | | | | 0 The counter stops running when it next reaches 0 and continues running again when no longer in Debug mode. |
| 1 The counter always runs when in Debug mode. | | | | |
| 1 | MODE | RW | 0 | Counter Mode |
| | | | | Value Description |
| | | | | 0 The counter counts down from the load value to 0 and then wraps back to the load value (Count-Down mode). |
| 1 The counter counts up from 0 to the load value, back down to 0, and then repeats (Count-Up/Down mode). | | | | |
| 0 | ENABLE | RW | 0 | PWM Block Enable |
| | | | | Note: Disabling the PWM by clearing the <code>ENABLE</code> bit does not clear the <code>COUNT</code> field of the <code>PWMnCOUNT</code> register. Before re-enabling the PWM (<code>ENABLE = 0x1</code>), the <code>COUNT</code> field should be cleared by resetting the PWM registers through the <code>SRPWM</code> register in the System Control Module. |
| | | | | Value Description |
| 0 The entire PWM generation block is disabled and not clocked. | | | | |
| 1 The PWM generation block is enabled and produces PWM signals. | | | | |

Register 16: PWM0 Interrupt and Trigger Enable (PWM0INTEN), offset 0x044

Register 17: PWM1 Interrupt and Trigger Enable (PWM1INTEN), offset 0x084

Register 18: PWM2 Interrupt and Trigger Enable (PWM2INTEN), offset 0x0C4

Register 19: PWM3 Interrupt and Trigger Enable (PWM3INTEN), offset 0x104

These registers control the interrupt and ADC trigger generation capabilities of the PWM generators (**PWM0INTEN** controls the PWM generator 0 block, and so on). The events that can cause an interrupt, or an ADC trigger are:

- The counter being equal to the load register
- The counter being equal to zero
- The counter being equal to the **PWMnCMPA** register while counting up
- The counter being equal to the **PWMnCMPA** register while counting down
- The counter being equal to the **PWMnCMPB** register while counting up
- The counter being equal to the **PWMnCMPB** register while counting down

Any combination of these events can generate either an interrupt or an ADC trigger, though no determination can be made as to the actual event that caused an ADC trigger if more than one is specified. The **PWMnRIS** register provides information about which events have caused raw interrupts.

Register 20: PWM0 Raw Interrupt Status (PWM0RIS), offset 0x048

Register 21: PWM1 Raw Interrupt Status (PWM1RIS), offset 0x088

Register 22: PWM2 Raw Interrupt Status (PWM2RIS), offset 0x0C8

Register 23: PWM3 Raw Interrupt Status (PWM3RIS), offset 0x108

These registers provide the current set of interrupt sources that are asserted, regardless of whether they cause an interrupt to be asserted to the controller (**PWM0RIS** controls the PWM generator 0 block, and so on). If a bit is set, the event has occurred; if a bit is clear, the event has not occurred. Bits in this register are cleared by writing a 1 to the corresponding bit in the **PWMnISC** register.

Register 24: PWM0 Interrupt Status and Clear (PWM0ISC), offset 0x04C

Register 25: PWM1 Interrupt Status and Clear (PWM1ISC), offset 0x08C

Register 26: PWM2 Interrupt Status and Clear (PWM2ISC), offset 0x0CC

Register 27: PWM3 Interrupt Status and Clear (PWM3ISC), offset 0x10C

These registers provide the current set of interrupt sources that are asserted to the interrupt controller (**PWM0ISC** controls the PWM generator 0 block, and so on). A bit is set if the event has occurred and is enabled in the **PWMnINTEN** register; if a bit is clear, the event has not occurred or is not enabled. These are RW1C registers; writing a 1 to a bit position clears the corresponding interrupt reason.

Note: The interrupt status can only be cleared one PWM Clock cycle after the interrupt occurs. The larger the PWM Clock Divider (**PWMDIV**) value in **PWMCC** register, the longer the system delay is to clear the interrupt.

Register 28: PWM0 Load (PWM0LOAD), offset 0x050

Register 29: PWM1 Load (PWM1LOAD), offset 0x090

Register 30: PWM2 Load (PWM2LOAD), offset 0x0D0

Register 31: PWM3 Load (PWM3LOAD), offset 0x110

These registers contain the load value for the PWM counter (**PWM0LOAD** controls the PWM generator 0 block, and so on). Based on the counter mode configured by the **MODE** bit in the **PWMnCTL** register, this value is either loaded into the counter after it reaches zero or is the limit of up-counting after which the counter decrements back to zero. When this value matches the counter, a pulse is output which can be configured to drive the generation of the pwmA and/or pwmB signal (via the **PWMnGENA/PWMnGENB** register) or drive an interruptor ADC trigger (via the **PWMnINTEN** register).

If the Load Value Update mode is locally synchronized (based on the **LOADUPD** field encoding in the **PWMnCTL** register), the 16-bit **LOAD** value is used the next time the counter reaches zero. If the update mode is globally synchronized, it is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 1939). If this register is re-written before the actual update occurs, the previous value is never used and is lost.

|-----------|----------|------|--------|---|
| 31:16 | reserved | RO | 0x0000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 15:0 | LOAD | RW | 0x0000 | Counter Load Value The counter load value. |

Register 32: PWM0 Counter (PWM0COUNT), offset 0x054**Register 33: PWM1 Counter (PWM1COUNT), offset 0x094****Register 34: PWM2 Counter (PWM2COUNT), offset 0x0D4****Register 35: PWM3 Counter (PWM3COUNT), offset 0x114**

These registers contain the current value of the PWM counter (**PWM0COUNT** is the value of the PWM generator 0 block, and so on). When this value matches zero or the value in the **PWMnLOAD**, **PWMnCMPA**, or **PWMnCMPB** registers, a pulse is output which can be configured to drive the generation of a PWM signal or drive an interrupt or ADC trigger.

Note: Disabling the PWM by clearing the **ENABLE** bit does not clear the **COUNT** field of the **PWMnCOUNT** register. Before re-enabling the PWM (**ENABLE** = 0x1), the **COUNT** field should be cleared by resetting the PWM registers through the **SRPWM** register in the System Control Module.

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|--------|---|
| 31:16 | reserved | RO | 0x0000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 15:0 | COUNT | RO | 0x0000 | Counter Value The current value of the counter. |

Register 36: PWM0 Compare A (PWM0CMPA), offset 0x058

Register 37: PWM1 Compare A (PWM1CMPA), offset 0x098

Register 38: PWM2 Compare A (PWM2CMPA), offset 0x0D8

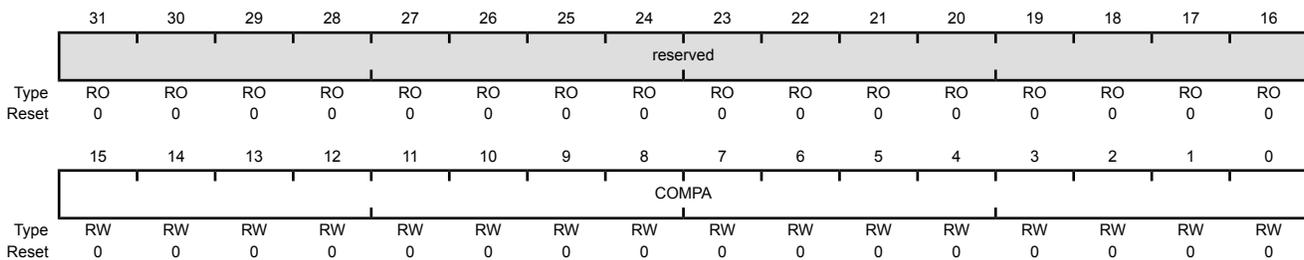

Register 39: PWM3 Compare A (PWM3CMPA), offset 0x118

These registers contain a value to be compared against the counter (**PWM0CMPA** controls the PWM generator 0 block, and so on). When this value matches the counter, a pulse is output which can be configured to drive the generation of the pwmA and pwmB signals (via the **PWMnGENA** and **PWMnGENB** registers) or drive an interrupt or ADC trigger (via the **PWMnINTEN** register). If the value of this register is greater than the **PWMnLOAD** register (see page 1976), then no pulse is ever output.

If the comparator A update mode is locally synchronized (based on the **COMPAUPD** bit in the **PWMnCTL** register), the 16-bit **COMPA** value is used the next time the counter reaches zero. If the update mode is globally synchronized, it is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 1939). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

| 31:16 | reserved | RO | 0x00 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 15:0 | COMPA | RW | 0x00 | Comparator A Value The value to be compared against the counter. |

Register 40: PWM0 Compare B (PWM0CMPB), offset 0x05C**Register 41: PWM1 Compare B (PWM1CMPB), offset 0x09C****Register 42: PWM2 Compare B (PWM2CMPB), offset 0x0DC****Register 43: PWM3 Compare B (PWM3CMPB), offset 0x11C**

These registers contain a value to be compared against the counter (**PWM0CMPB** controls the PWM generator 0 block, and so on). When this value matches the counter, a pulse is output which can be configured to drive the generation of the pwmA and pwmB signals (via the **PWMnGENA** and **PWMnGENB** registers) or drive an interrupt or ADC trigger (via the **PWMnINTEN** register). If the value of this register is greater than the **PWMnLOAD** register, no pulse is ever output.

If the comparator B update mode is locally synchronized (based on the **COMPBUPD** bit in the **PWMnCTL** register), the 16-bit **COMPB** value is used the next time the counter reaches zero. If the update mode is globally synchronized, it is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 1939). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

|-----------|----------|------|--------|---|
| 31:16 | reserved | RO | 0x0000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 15:0 | COMPB | RW | 0x0000 | Comparator B Value The value to be compared against the counter. |

Register 44: PWM0 Generator A Control (PWM0GENA), offset 0x060

Register 45: PWM1 Generator A Control (PWM1GENA), offset 0x0A0

Register 46: PWM2 Generator A Control (PWM2GENA), offset 0x0E0

Register 47: PWM3 Generator A Control (PWM3GENA), offset 0x120

These registers control the generation of the pwmA signal based on the load and zero output pulses from the counter, as well as the compare A and compare B pulses from the comparators (**PWM0GENA** controls the PWM generator 0 block, and so on). When the counter is running in Count-Down mode, only four of these events occur; when running in Count-Up/Down mode, all six occur. These events provide great flexibility in the positioning and duty cycle of the resulting PWM signal.

The **PWM0GENA** register controls generation of the pwm0A signal; **PWM1GENA**, the pwm1A signal; **PWM2GENA**, the pwm2A signal; and **PWM3GENA**, the pwm3A signal.

If a zero or load event coincides with a compare A or compare B event, the zero or load action is taken and the compare A or compare B action is ignored. If a compare A event coincides with a compare B event, the compare A action is taken and the compare B action is ignored.

If the Generator A update mode is immediate (based on the **GENAUPD** field encoding in the **PWMnCTL** register), the **ACTCMPBD**, **ACTCMPBU**, **ACTCMPAD**, **ACTCMPAU**, **ACTLOAD**, and **ACTZERO** values are used immediately. If the update mode is locally synchronized, these values are used the next time the counter reaches zero. If the update mode is globally synchronized, these values are used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 1939). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

Register 52: PWM0 Dead-Band Control (PWM0DBCTL), offset 0x068

Register 53: PWM1 Dead-Band Control (PWM1DBCTL), offset 0x0A8

Register 54: PWM2 Dead-Band Control (PWM2DBCTL), offset 0x0E8

Register 55: PWM3 Dead-Band Control (PWM3DBCTL), offset 0x128

The **PWMnDBCTL** register controls the dead-band generator, which produces the M_nP_{WMn} signals based on the *pwmA* and *pwmB* signals. When disabled, the *pwmA* signal passes through to the *pwmA'* signal and the *pwmB* signal passes through to the *pwmB'* signal. When dead-band control is enabled, the *pwmB* signal is ignored, the *pwmA'* signal is generated by delaying the rising edge(s) of the *pwmA* signal by the value in the **PWMnDBRISE** register (see page 1987), and the *pwmB'* signal is generated by inverting the *pwmA* signal and delaying the falling edge(s) of the *pwmA* signal by the value in the **PWMnDBFALL** register (see page 1988). The Output Control block outputs the *pwm0A'* signal on the M_nP_{WM0} signal and the *pwm0B'* signal on the M_nP_{WM1} signal. In a similar manner, M_nP_{WM2} and M_nP_{WM3} are produced from the *pwm1A'* and *pwm1B'* signals, M_nP_{WM4} and M_nP_{WM5} are produced from the *pwm2A'* and *pwm2B'* signals, and M_nP_{WM6} and M_nP_{WM7} are produced from the *pwm3A'* and *pwm3B'* signals.

If the Dead-Band Control mode is immediate (based on the **DBCTLUPD** field encoding in the **PWMnCTL** register), the **ENABLE** bit value is used immediately. If the update mode is locally synchronized, this value is used the next time the counter reaches zero. If the update mode is globally synchronized, this value is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 1939). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

| 0 | ENABLE | RW | 0 | Dead-Band Generator Enable |
| | | | | Value Description |
| | | | 0 | The <i>pwmA</i> and <i>pwmB</i> signals pass through to the <i>pwmA'</i> and <i>pwmB'</i> signals unmodified. |
| | | | 1 | The dead-band generator modifies the <i>pwmA</i> signal by inserting dead bands into the <i>pwmA'</i> and <i>pwmB'</i> signals. |

Register 56: PWM0 Dead-Band Rising-Edge Delay (PWM0DBRISE), offset 0x06C

Register 57: PWM1 Dead-Band Rising-Edge Delay (PWM1DBRISE), offset 0x0AC

Register 58: PWM2 Dead-Band Rising-Edge Delay (PWM2DBRISE), offset 0x0EC

Register 59: PWM3 Dead-Band Rising-Edge Delay (PWM3DBRISE), offset 0x12C

The **PWMnDBRISE** register contains the number of clock cycles to delay the rising edge of the pwmA signal when generating the pwmA' signal. If the dead-band generator is disabled through the **PWMnDBCTL** register, this register is ignored. If the value of this register is larger than the width of a High pulse on the pwmA signal, the rising-edge delay consumes the entire High time of the signal, resulting in no High time on the output. Care must be taken to ensure that the pwmA High time always exceeds the rising-edge delay.

If the Dead-Band Rising-Edge Delay mode is immediate (based on the **DBRISEUPD** field encoding in the **PWMnCTL** register), the 12-bit **RISEDELAY** value is used immediately. If the update mode is locally synchronized, this value is used the next time the counter reaches zero. If the update mode is globally synchronized, this value is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 1939). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

| Bit/Field | Name | Type | Reset | Description |
|-----------|-----------|------|----------|---|
| 31:12 | reserved | RO | 0x0000.0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 11:0 | RISEDELAY | RW | 0x000 | Dead-Band Rise Delay The number of clock cycles to delay the rising edge of pwmA' after the rising edge of pwmA. |

Register 60: PWM0 Dead-Band Falling-Edge-Delay (PWM0DBFALL), offset 0x070

Register 61: PWM1 Dead-Band Falling-Edge-Delay (PWM1DBFALL), offset 0x0B0

Register 62: PWM2 Dead-Band Falling-Edge-Delay (PWM2DBFALL), offset 0x0F0

Register 63: PWM3 Dead-Band Falling-Edge-Delay (PWM3DBFALL), offset 0x130

The **PWMnDBFALL** register contains the number of clock cycles to delay the rising edge of the pwmB' signal from the falling edge of the pwmA signal. If the dead-band generator is disabled through the **PWMnDBCTL** register, this register is ignored. If the value of this register is larger than the width of a Low pulse on the pwmA signal, the falling-edge delay consumes the entire Low time of the signal, resulting in no Low time on the output. Care must be taken to ensure that the pwmA Low time always exceeds the falling-edge delay.

If the Dead-Band Falling-Edge-Delay mode is immediate (based on the **DBFALLUP** field encoding in the **PWMnCTL** register), the 12-bit **FALLDELAY** value is used immediately. If the update mode is locally synchronized, this value is used the next time the counter reaches zero. If the update mode is globally synchronized, this value is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 1939). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

Register 64: PWM0 Fault Source 0 (PWM0FLTSRC0), offset 0x074**Register 65: PWM1 Fault Source 0 (PWM1FLTSRC0), offset 0x0B4****Register 66: PWM2 Fault Source 0 (PWM2FLTSRC0), offset 0x0F4****Register 67: PWM3 Fault Source 0 (PWM3FLTSRC0), offset 0x134**

This register specifies which fault pin inputs are used to generate a fault condition. Each bit in the following register indicates whether the corresponding fault pin is included in the fault condition. All enabled fault pins are ORed together to form the **PWMnFLTSRC0** portion of the fault condition. The **PWMnFLTSRC0** fault condition is then ORed with the **PWMnFLTSRC1** fault condition to generate the final fault condition for the PWM generator.

If the **FLTSRC** bit in the **PWMnCTL** register (see page 1964) is clear, only the **Fault0** signal affects the fault condition generated. Otherwise, sources defined in **PWMnFLTSRC0** and **PWMnFLTSRC1** affect the fault condition generated.

Register 68: PWM0 Fault Source 1 (PWM0FLTSRC1), offset 0x078**Register 69: PWM1 Fault Source 1 (PWM1FLTSRC1), offset 0x0B8****Register 70: PWM2 Fault Source 1 (PWM2FLTSRC1), offset 0x0F8****Register 71: PWM3 Fault Source 1 (PWM3FLTSRC1), offset 0x138**

This register specifies which digital comparator triggers from the ADC are used to generate a fault condition. Each bit in the following register indicates whether the corresponding digital comparator trigger is included in the fault condition. All enabled digital comparator triggers are ORed together to form the **PWMnFLTSRC1** portion of the fault condition. The **PWMnFLTSRC1** fault condition is then ORed with the **PWMnFLTSRC0** fault condition to generate the final fault condition for the PWM generator.

If the **FLTSRC** bit in the **PWMnCTL** register (see page 1964) is clear, only the PWM_{Fault0} pin affects the fault condition generated. Otherwise, sources defined in **PWMnFLTSRC0** and **PWMnFLTSRC1** affect the fault condition generated.

Register 72: PWM0 Minimum Fault Period (PWM0MINFLTPER), offset 0x07C

Register 73: PWM1 Minimum Fault Period (PWM1MINFLTPER), offset 0x0BC

Register 74: PWM2 Minimum Fault Period (PWM2MINFLTPER), offset 0x0FC

Register 75: PWM3 Minimum Fault Period (PWM3MINFLTPER), offset 0x13C

If the `MINFLTPER` bit in the `PWMnCTL` register is set, this register specifies the 16-bit time-extension value to be used in extending the fault condition. The value is loaded into a 16-bit down counter, and the counter value is used to extend the fault condition. The fault condition is released in the clock immediately after the counter value reaches 0. The fault condition is asynchronous to the PWM clock; and the delay value is the product of the PWM clock period and the (MFP field value + 1) or (MFP field value + 2) depending on when the fault condition asserts with respect to the PWM clock. The counter decrements at the PWM clock rate, without pause or condition.

Register 80: PWM0 Fault Status 0 (PWM0FLTSTAT0), offset 0x804

Register 81: PWM1 Fault Status 0 (PWM1FLTSTAT0), offset 0x884

Register 82: PWM2 Fault Status 0 (PWM2FLTSTAT0), offset 0x904

Register 83: PWM3 Fault Status 0 (PWM3FLTSTAT0), offset 0x984

Along with the **PWMnFLTSTAT1** register, this register provides status regarding the fault condition inputs.

If the **LATCH** bit in the **PWMnCTL** register is clear, the contents of the **PWMnFLTSTAT0** register are read-only (RO) and provide the current state of the **MnFAULTn** inputs.

If the **LATCH** bit in the **PWMnCTL** register is set, the contents of the **PWMnFLTSTAT0** register are read / write 1 to clear (RW1C) and provide a latched version of the **MnFAULTn** inputs. In this mode, the register bits are cleared by writing a 1 to a set bit. The **MnFAULTn** inputs are recorded after their sense is adjusted in the generator.

The contents of this register can only be written if the fault source extensions are enabled (the **FLTSRC** bit in the **PWMnCTL** register is set).

Note: The fault status registers, **PWMnFLTSTAT0** and **PWMnFLTSTAT1**, reflect the status of all fault sources, regardless of what fault sources are enabled for that particular generator.

Register 84: PWM0 Fault Status 1 (PWM0FLTSTAT1), offset 0x808

Register 85: PWM1 Fault Status 1 (PWM1FLTSTAT1), offset 0x888

Register 86: PWM2 Fault Status 1 (PWM2FLTSTAT1), offset 0x908

Register 87: PWM3 Fault Status 1 (PWM3FLTSTAT1), offset 0x988

Along with the **PWMnFLTSTAT0** register, this register provides status regarding the fault condition inputs.

If the **LATCH** bit in the **PWMnCTL** register is clear, the contents of the **PWMnFLTSTAT1** register are read-only (RO) and provide the current state of the digital comparator triggers.

If the **LATCH** bit in the **PWMnCTL** register is set, the contents of the **PWMnFLTSTAT1** register are read / write 1 to clear (RW1C) and provide a latched version of the digital comparator triggers. In this mode, the register bits are cleared by writing a 1 to a set bit. The contents of this register can only be written if the fault source extensions are enabled (the **FLTSRC** bit in the **PWMnCTL** register is set).

Note: The fault status registers, **PWMnFLTSTAT0** and **PWMnFLTSTAT1**, reflect the status of all fault sources, regardless of what fault sources are enabled for that particular generator.

29 Quadrature Encoder Interface (QEI)

A quadrature encoder, also known as a 2-channel incremental encoder, converts linear displacement into a pulse signal. By monitoring both the number of pulses and the relative phase of the two signals, you can track the position, direction of rotation, and speed. In addition, a third channel, or index signal, can be used to reset the position counter.

The TM4C129XKCZAD quadrature encoder interface (QEI) module interprets the code produced by a quadrature encoder wheel to integrate position over time and determine direction of rotation. In addition, it can capture a running estimate of the velocity of the encoder wheel.

The TM4C129XKCZAD microcontroller includes one QEI module with the following features:

- Position integrator that tracks the encoder position
- Programmable noise filter on the inputs
- Velocity capture using built-in timer
- The input frequency of the QEI inputs may be as high as 1/4 of the processor frequency (for example, 12.5 MHz for a 50-MHz system)
- Interrupt generation on:
 - Index pulse
 - Velocity-timer expiration
 - Direction change
 - Quadrature error detection

29.1 Block Diagram

Figure 29-1 on page 2005 provides an internal block diagram of a TM4C129XKCZAD QEI module. The PhA and PhB inputs shown in this diagram are the internal signals that enter the Quadrature Encoder after the external signals, $PhAn$ and $PhBn$, have passed through inversion and swapping logic shown in Figure 29-2 on page 2006. The QEI module has the option of inverting and/or swapping the incoming signals.

Note: Any references in this chapter to PhA and PhB refer to the internal PhA and PhB inputs that enter the Quadrature Encoder after the external signals, $PhAn$ and $PhBn$, have passed through inversion and swapping logic that is enabled through the **QEI Control (QEICTL)** register.

Figure 29-1. QEI Block Diagram

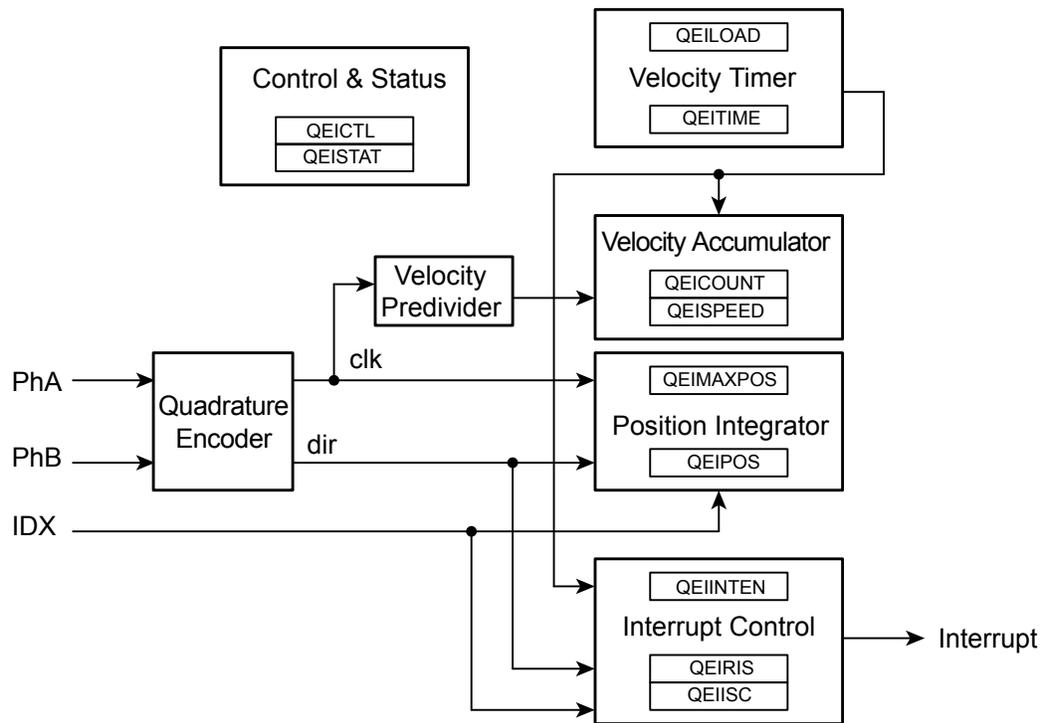

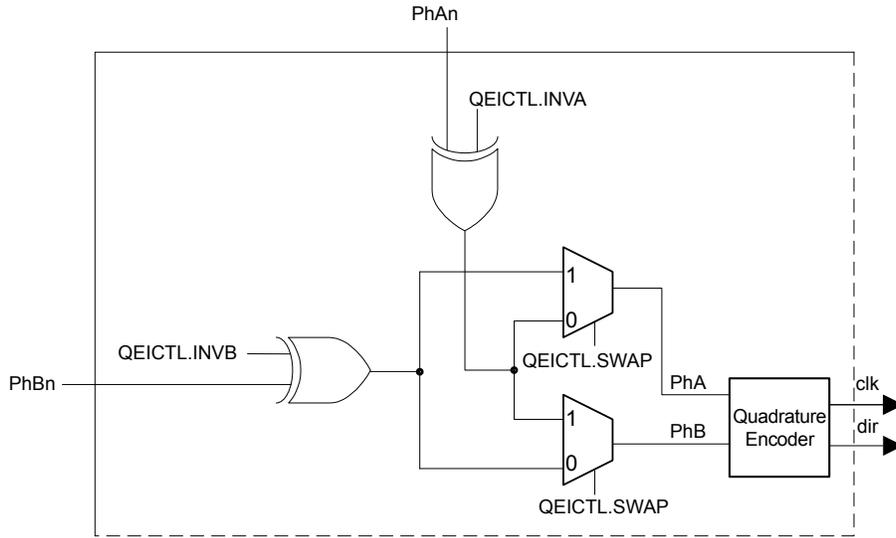

Figure 29-2 on page 2006 shows the logic that is provided to allow the `PhAn` and `PhBn` signals to be inverted and/or swapped.

Figure 29-2. QEI Input Signal Logic

29.2 Signal Description

The following table lists the external signals of the QEI module and describes the function of each. The QEI signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for these QEI signals. The **AFSEL** bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 803) should be set to choose the QEI function. The number in parentheses is the encoding that must be programmed into the **PMC_n** field in the **GPIO Port Control (GPIOCTL)** register (page 820) to assign the QEI signal to the specified GPIO port pin. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 772.

Table 29-1. QEI Signals (212BGA)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description |
|----------|------------|--------------------------|----------|-------------|-----------------------|
| IDX0 | J18 U10 | PL3 (6) PS6 (6) | I | TTL | QEI module 0 index. |
| PhA0 | H19 V9 | PL1 (6) PS4 (6) | I | TTL | QEI module 0 phase A. |
| PhB0 | G18 T13 | PL2 (6) PS5 (6) | I | TTL | QEI module 0 phase B. |

29.3 Functional Description

The QEI module interprets the two-bit gray code produced by a quadrature encoder wheel to integrate position over time and determine direction of rotation. In addition, it can capture a running estimate of the velocity of the encoder wheel.

The position integrator and velocity capture can be independently enabled, though the position integrator must be enabled before the velocity capture can be enabled. The two phase signals,

Ph_{An} and Ph_{Bn} , can be swapped before being interpreted by the QEI module to change the meaning of forward and backward and to correct for miswiring of the system. Alternatively, the phase signals can be interpreted as a clock and direction signal as output by some encoders.

The QEI module input signals have a digital noise filter on them that can be enabled to prevent spurious operation. The noise filter requires that the inputs be stable for a specified number of consecutive clock cycles before updating the edge detector. The filter is enabled by the `FILTEN` bit in the **QEI Control (QEICTL)** register. The frequency of the input update is programmable using the `FILTCNT` bit field in the **QEICTL** register.

The QEI module supports two modes of signal operation: quadrature phase mode and clock/direction mode. In quadrature phase mode, the encoder produces two clocks that are 90 degrees out of phase; the edge relationship is used to determine the direction of rotation. In clock/direction mode, the encoder produces a clock signal to indicate steps and a direction signal to indicate the direction of rotation. This mode is determined by the `SIGMODE` bit of the **QEICTL** register (see page 2011).

When the QEI module is set to use the quadrature phase mode (`SIGMODE` bit is clear), the capture mode for the position integrator can be set to update the position counter on every edge of the Ph_A signal or to update on every edge of both Ph_A and Ph_B . Updating the position counter on every Ph_A and Ph_B edge provides more positional resolution at the cost of less range in the positional counter.

When edges on Ph_A lead edges on Ph_B , the position counter is incremented. When edges on Ph_B lead edges on Ph_A , the position counter is decremented. When a rising and falling edge pair is seen on one of the phases without any edges on the other, the direction of rotation has changed.

The positional counter is automatically reset on one of two conditions: sensing the index pulse or reaching the maximum position value. The reset mode is determined by the `RESMODE` bit of the **QEICTL** register.

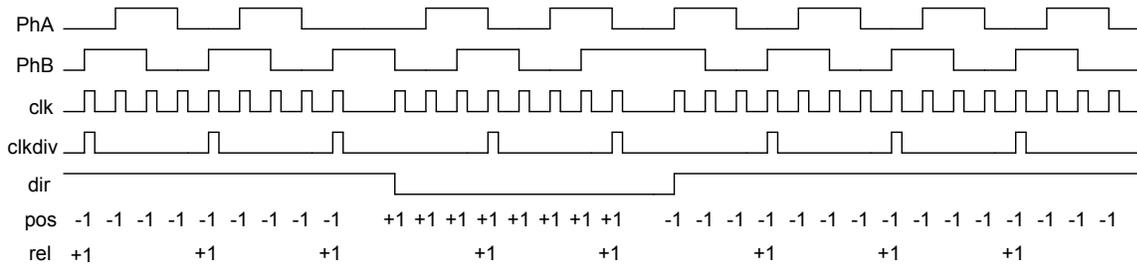

When `RESMODE` is set, the positional counter is reset when the index pulse is sensed. This mode limits the positional counter to the values $[0:N-1]$, where N is the number of phase edges in a full revolution of the encoder wheel. The **QEI Maximum Position (QEIMAXPOS)** register must be programmed with $N-1$ so that the reverse direction from position 0 can move the position counter to $N-1$. In this mode, the position register contains the absolute position of the encoder relative to the index (or home) position once an index pulse has been seen.

When `RESMODE` is clear, the positional counter is constrained to the range $[0:M]$, where M is the programmable maximum value. The index pulse is ignored by the positional counter in this mode.

Velocity capture uses a configurable timer and a count register. The timer counts the number of phase edges (using the same configuration as for the position integrator) in a given time period. The edge count from the previous time period is available to the controller via the **QEI Velocity (QEISPEED)** register, while the edge count for the current time period is being accumulated in the **QEI Velocity Counter (QEICOUNT)** register. As soon as the current time period is complete, the total number of edges counted in that time period is made available in the **QEISPEED** register (overwriting the previous value), the **QEICOUNT** register is cleared, and counting commences on a new time period. The number of edges counted in a given time period is directly proportional to the velocity of the encoder.

Figure 29-3 on page 2008 shows how the TM4C129XKCZAD quadrature encoder converts the phase input signals into clock pulses, the direction signal, and how the velocity predivider operates (in Divide by 4 mode).

Figure 29-3. Quadrature Encoder and Velocity Predivider Operation

The period of the timer is configurable by specifying the load value for the timer in the **QEI Timer Load (QEILOAD)** register. When the timer reaches zero, an interrupt can be triggered, and the hardware reloads the timer with the **QEILOAD** value and continues to count down. At lower encoder speeds, a longer timer period is required to be able to capture enough edges to have a meaningful result. At higher encoder speeds, both a shorter timer period and/or the velocity predivider can be used.

The following equation converts the velocity counter value into an rpm value:

$$\text{rpm} = (\text{clock} * (2 ^ \text{VELDIV}) * \text{SPEED} * 60) \div (\text{LOAD} * \text{ppr} * \text{edges})$$

where:

clock is the controller clock rate

ppr is the number of pulses per revolution of the physical encoder

edges is 2 or 4, based on the capture mode set in the **QEICTL** register (2 for CAPMODE clear and 4 for CAPMODE set)

For example, consider a motor running at 600 rpm. A 2048 pulse per revolution quadrature encoder is attached to the motor, producing 8192 phase edges per revolution. With a velocity predivider of ÷1 (VELDIV is clear) and clocking on both PhA and PhB edges, this results in 81,920 pulses per second (the motor turns 10 times per second). If the timer were clocked at 10,000 Hz, and the load value was 2,500 (¼ of a second), it would count 20,480 pulses per update. Using the above equation:

$$\text{rpm} = (10000 * 1 * 20480 * 60) \div (2500 * 2048 * 4) = 600 \text{ rpm}$$

Now, consider that the motor is sped up to 3000 rpm. This results in 409,600 pulses per second, or 102,400 every ¼ of a second. Again, the above equation gives:

$$\text{rpm} = (10000 * 1 * 102400 * 60) \div (2500 * 2048 * 4) = 3000 \text{ rpm}$$

Care must be taken when evaluating this equation because intermediate values may exceed the capacity of a 32-bit integer. In the above examples, the clock is 10,000 and the divider is 2,500; both could be predivided by 100 (at compile time if they are constants) and therefore be 100 and 25. In fact, if they were compile-time constants, they could also be reduced to a simple multiply by 4, cancelled by the ÷4 for the edge-count factor.

Important: Reducing constant factors at compile time is the best way to control the intermediate values of this equation and reduce the processing requirement of computing this equation.

The division can be avoided by selecting a timer load value such that the divisor is a power of 2; a simple shift can therefore be done in place of the division. For encoders with a power of 2 pulses per revolution, the load value can be a power of 2. For other encoders, a load value must be selected such that the product is very close to a power of 2. For example, a 100 pulse-per-revolution encoder

could use a load value of 82, resulting in 32,800 as the divisor, which is 0.09% above 2^{14} . In this case a shift by 15 would be an adequate approximation of the divide in most cases. If absolute accuracy were required, the microcontroller's divide instruction could be used.

The QEI module can produce a controller interrupt on several events: phase error, direction change, reception of the index pulse, and expiration of the velocity timer. Standard masking, raw interrupt status, interrupt status, and interrupt clear capabilities are provided.

29.4 Initialization and Configuration

The following example shows how to configure the Quadrature Encoder module to read back an absolute position:

1. Enable the QEI clock using the **RCGCQEI** register in the System Control module (see page 416).
2. Enable the clock to the appropriate GPIO module via the **RCGCGPIO** register in the System Control module (see page 399).
3. In the GPIO module, enable the appropriate pins for their alternate function using the **GPIOAFSEL** register. To determine which GPIOs to configure, see Table 31-4 on page 2064.
4. Configure the **PMC_n** fields in the **GPIOPCTL** register to assign the QEI signals to the appropriate pins (see page 820 and Table 31-5 on page 2081).
5. Configure the quadrature encoder to capture edges on both signals and maintain an absolute position by resetting on index pulses. A 1000-line encoder with four edges per line, results in 4000 pulses per revolution; therefore, set the maximum position to 3999 (0xF9F) as the count is zero-based.
 - Write the **QEICTL** register with the value of 0x0000.0018.
 - Write the **QEIMAXPOS** register with the value of 0x0000.0F9F.
6. Enable the quadrature encoder by setting bit 0 of the **QEICTL** register.

Note: Once the QEI module has been enabled by setting the **ENABLE** bit in the **QEICTL** register, it cannot be disabled. The only way to clear the **ENABLE** bit is to reset the module using the **Quadrature Encoder Interface Software Reset (SRQEI)** register.
7. Delay until the encoder position is required.
8. Read the encoder position by reading the **QEI Position (QEIPOS)** register value.

Note: If the application requires the quadrature encoder to have a specific initial position, this value must be programmed in the **QEIPOS** register after the quadrature encoder has been enabled by setting the **ENABLE** bit in the **QEICTL** register.

29.5 Register Map

Table 29-2 on page 2010 lists the QEI registers. The offset listed is a hexadecimal increment to the register's address, relative to the module's base address:

- QEI0: 0x4002.C000

Note that the QEI module clock must be enabled before the registers can be programmed (see page 416). There must be a delay of 3 system clocks after the QEI module clock is enabled before any QEI module registers are accessed.

29.6 Register Descriptions

The remainder of this section lists and describes the QEI registers, in numerical order by address offset.

Register 1: QEI Control (QEICTL), offset 0x000

This register contains the configuration of the QEI module. Separate enables are provided for the quadrature encoder and the velocity capture blocks; the quadrature encoder must be enabled in order to capture the velocity, but the velocity does not need to be captured in applications that do not need it. The phase signal interpretation, phase swap, Position Update mode, Position Reset mode, and velocity predivider are all set via this register.

QEI Control (QEICTL)

QEI0 base: 0x4002.C000

|-----------|----------|------|-------------|--|
| 31:0 | POSITION | RW | 0x0000.0000 | Current Position Integrator Value The current value of the position integrator. |

Register 4: QEI Maximum Position (QEIMAXPOS), offset 0x00C

This register contains the maximum value of the position integrator. When moving forward, the position register resets to zero when it increments past this value. When moving in reverse, the position register resets to this value when it decrements from zero.

QEI Maximum Position (QEIMAXPOS)

QEI0 base: 0x4002.C000
 Offset 0x00C
 Type RW, reset 0x0000.0000

| Bit/Field | Name | Type | Reset | Description |
|-----------|--------|------|-------------|--|
| 31:0 | MAXPOS | RW | 0x0000.0000 | Maximum Position Integrator Value The maximum value of the position integrator. |

Register 5: QEI Timer Load (QEILOAD), offset 0x010

This register contains the load value for the velocity timer. Because this value is loaded into the timer on the clock cycle after the timer is zero, this value should be one less than the number of clocks in the desired period. So, for example, to have 2000 decimal clocks per timer period, this register should contain 1999 decimal.

QEI Timer Load (QEILOAD)

QEI0 base: 0x4002.C000

Offset 0x010

Type RW, reset 0x0000.0000

| | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|-------|------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|

| Bit/Field | Name | Type | Reset | Description |
|-----------|------|------|-------------|---|
| 31:0 | LOAD | RW | 0x0000.0000 | Velocity Timer Load Value The load value for the velocity timer. |

Register 6: QEI Timer (QEITIME), offset 0x014

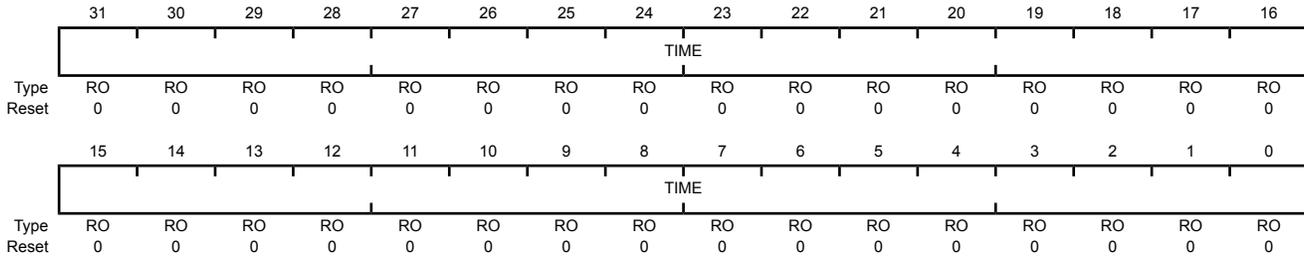

This register contains the current value of the velocity timer. This counter does not increment when the VELEN bit in the QEICTL register is clear.

QEI Timer (QEITIME)

QEI0 base: 0x4002.C000

Offset 0x014

Type RO, reset 0x0000.0000

| Bit/Field | Name | Type | Reset | Description |
|-----------|------|------|-------------|--|
| 31:0 | TIME | RO | 0x0000.0000 | Velocity Timer Current Value The current value of the velocity timer. |

Register 7: QEI Velocity Counter (QEICOUNT), offset 0x018

This register contains the running count of velocity pulses for the current time period. Because this count is a running total, the time period to which it applies cannot be known with precision (that is, a read of this register does not necessarily correspond to the time returned by the **QEITIME** register because there is a small window of time between the two reads, during which either value may have changed). The **QEISPEED** register should be used to determine the actual encoder velocity; this register is provided for information purposes only. This counter does not increment when the **VELEN** bit in the **QEICTL** register is clear.

QEI Velocity Counter (QEICOUNT)

QEI0 base: 0x4002.C000

Offset 0x018

Type RO, reset 0x0000.0000

| | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Type | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit/Field | Name | Type | Reset | Description |
|-----------|-------|------|-------------|--|
| 31:0 | COUNT | RO | 0x0000.0000 | Velocity Pulse Count The running total of encoder pulses during this velocity timer period. |

Register 8: QEI Velocity (QEISPEED), offset 0x01C

This register contains the most recently measured velocity of the quadrature encoder. This value corresponds to the number of velocity pulses counted in the previous velocity timer period. This register does not update when the `VELEN` bit in the `QEICTL` register is clear.

QEI Velocity (QEISPEED)

QEI0 base: 0x4002.C000
 Offset 0x01C
 Type RO, reset 0x0000.0000

| Bit/Field | Name | Type | Reset | Description |
|-----------|-------|------|-------------|--|
| 31:0 | SPEED | RO | 0x0000.0000 | Velocity The measured speed of the quadrature encoder in pulses per period. |

Register 9: QEI Interrupt Enable (QEIINTEN), offset 0x020

This register contains enables for each of the QEI module interrupts. An interrupt is asserted to the interrupt controller if the corresponding bit in this register is set.

QEI Interrupt Enable (QEIINTEN)

QEI0 base: 0x4002.C000

Offset 0x020

Type RW, reset 0x0000.0000

|-----------|----------|------|------------|--|
| 31:4 | reserved | RO | 0x0000.000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 3 | INTERROR | RW | 0 | Phase Error Interrupt Enable Note: The <code>INTERROR</code> bit is only applicable when the QEI is operating in quadrature phase mode (<code>SIGMODE=0</code>) and should be masked when <code>SIGMODE =1</code> . Value Description 0 The <code>INTERROR</code> interrupt is suppressed and not sent to the interrupt controller. 1 An interrupt is sent to the interrupt controller when the <code>INTERROR</code> bit in the <code>QEIRIS</code> register is set. |
| 2 | INTDIR | RW | 0 | Direction Change Interrupt Enable Value Description 0 The <code>INTDIR</code> interrupt is suppressed and not sent to the interrupt controller. 1 An interrupt is sent to the interrupt controller when the <code>INTDIR</code> bit in the <code>QEIRIS</code> register is set. |
| 1 | INTTIMER | RW | 0 | Timer Expires Interrupt Enable Value Description 0 The <code>INTTIMER</code> interrupt is suppressed and not sent to the interrupt controller. 1 An interrupt is sent to the interrupt controller when the <code>INTTIMER</code> bit in the <code>QEIRIS</code> register is set. |

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|-------|---|
| 0 | INTINDEX | RW | 0 | Index Pulse Detected Interrupt Enable |
| | | | | Value Description |
| | | | 0 | The <code>INTINDEX</code> interrupt is suppressed and not sent to the interrupt controller. |
| | | | 1 | An interrupt is sent to the interrupt controller when the <code>INTINDEX</code> bit in the QEIRIS register is set. |

Register 10: QEI Raw Interrupt Status (QEIRIS), offset 0x024

This register provides the current set of interrupt sources that are asserted, regardless of whether they cause an interrupt to be asserted to the controller (configured through the **QEIINTEN** register). If a bit is set, the latched event has occurred; if a bit is clear, the event in question has not occurred.

QEI Raw Interrupt Status (QEIRIS)

QEI0 base: 0x4002.C000

Offset 0x024

Type RO, reset 0x0000.0000

| | | | | | | | | | | | | | | | | |
|-------|----------|----|----|----|----|----|----|----|----|----|----|----|----------|--------|----------|----------|
| | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|------------|---|
| 31:4 | reserved | RO | 0x0000.000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 3 | INTERROR | RO | 0 | Phase Error Detected Note: The <code>INTERROR</code> bit is only applicable when the QEI is operating in quadrature phase mode (<code>SIGMODE=0</code>). Value Description 0 An interrupt has not occurred. 1 A phase error has been detected. This bit is cleared by writing a 1 to the <code>INTERROR</code> bit in the QEIISC register. |
| 2 | INTDIR | RO | 0 | Direction Change Detected Value Description 0 An interrupt has not occurred. 1 The rotation direction has changed This bit is cleared by writing a 1 to the <code>INTDIR</code> bit in the QEIISC register. |
| 1 | INTTIMER | RO | 0 | Velocity Timer Expired Value Description 0 An interrupt has not occurred. 1 The velocity timer has expired. This bit is cleared by writing a 1 to the <code>INTTIMER</code> bit in the QEIISC register. |

| Bit/Field | Name | Type | Reset | Description |
|-----------|----------|------|-------|--|
| 0 | INTINDEX | RO | 0 | Index Pulse Asserted |
| | | | | Value Description |
| | | | | 0 An interrupt has not occurred. |
| | | | | 1 The index pulse has occurred. |
| | | | | This bit is cleared by writing a 1 to the INTINDEX bit in the QEISC register. |

Register 11: QEI Interrupt Status and Clear (QEIISC), offset 0x028

This register provides the current set of interrupt sources that are asserted to the controller. If a bit is set, the latched event has occurred and is enabled to generate an interrupt; if a bit is clear the event in question has not occurred or is not enabled to generate an interrupt. This register is RW1C; writing a 1 to a bit position clears the bit and the corresponding interrupt reason.

QEI Interrupt Status and Clear (QEIISC)

QEI0 base: 0x4002.C000

Offset 0x028

| | | | | This bit is cleared by writing a 1. Clearing this bit also clears the INTINDEX bit in the QEIRIS register. |

30 Pin Diagram

The TM4C129XKCZAD microcontroller pin diagram is shown below.

Each GPIO signal is identified by its GPIO port unless it defaults to an alternate function on reset. In this case, the GPIO port name is followed by the default alternate function. To see a complete list of possible functions for each pin, see Table 31-5 on page 2081.

Figure 30-1. 212-Ball BGA Package Pin Diagram (Top View)

31 Signal Tables

The following tables list the signals available for each pin. Signals are configured as GPIOs on reset, except for those noted below. Use the **GPIOAMSEL** register (see page 819) to select analog mode. For a GPIO pin to be used for an alternate digital function, the corresponding bit in the **GPIOAFSEL** register (see page 803) must be set. Further pin muxing options are provided through the PMC_x bit field in the **GPIOPCTL** register (see page 820), which selects one of several available peripheral functions for that GPIO.

Important: Table 10-1 on page 773 shows special consideration GPIO pins. Most GPIO pins are configured as GPIOs and tri-stated by default (**GPIOAFSEL**=0, **GIODEN**=0, **GPIOPDR**=0, **GPIOPUR**=0, and **GPIOPCTL**=0). Special consideration pins may be programmed to a non-GPIO function or may have special commit controls out of reset. In addition, a Power-On-Reset (\overline{POR}) returns these GPIO to their original special consideration state.

Table 31-1. GPIO Pins With Special Considerations

| GPIO Pins | Default Reset State | GPIOAFSEL | GIODEN | GPIOPDR | GPIOPUR | GPIOPCTL | GPIOCR |
|-----------|---------------------|-----------|--------|---------|---------|----------|--------|
| PC[3:0] | JTAG/SWD | 1 | 1 | 0 | 1 | 0x1 | 0 |
| PD[7] | GPIO ^a | 0 | 0 | 0 | 0 | 0x0 | 0 |
| PE[7] | GPIO ^a | 0 | 0 | 0 | 0 | 0x0 | 0 |

a. This pin is configured as a GPIO by default but is locked and can only be reprogrammed by unlocking the pin in the **GPIOLOCK** register and uncommitting it by setting the **GPIOCR** register.

Table 31-2 on page 2029 shows the pin-to-signal-name mapping, including functional characteristics of the signals. Each possible alternate analog and digital function is listed for each pin.

Table 31-3 on page 2048 lists the signals in alphabetical order by signal name. If it is possible for a signal to be on multiple pins, each possible pin assignment is listed. The "Pin Mux" column indicates the GPIO and the encoding needed in the PMC_x bit field in the **GPIOPCTL** register.

Table 31-4 on page 2064 groups the signals by functionality, except for GPIOs. If it is possible for a signal to be on multiple pins, each possible pin assignment is listed.

Table 31-5 on page 2081 lists the GPIO pins and their analog and digital alternate functions. The A_{INx} analog signals go through an isolation circuit before reaching their circuitry. These signals are configured by clearing the corresponding **DEN** bit in the **GPIO Digital Enable (GIODEN)** register and setting the corresponding **AMSEL** bit in the **GPIO Analog Mode Select (GPIOAMSEL)** register. Other analog signals are 3.3-V tolerant and are connected directly to their circuitry ($C0-$, $C0+$, $C1-$, $C1+$, $C2-$, $C2+$, $USB0VBUS$, $USB0ID$). These signals are configured by clearing the **DEN** bit in the **GPIO Digital Enable (GIODEN)** register. The digital signals are enabled by setting the appropriate bit in the **GPIO Alternate Function Select (GPIOAFSEL)** and **GIODEN** registers and configuring the PMC_x bit field in the **GPIO Port Control (GPIOPCTL)** register to the numeric encoding shown in the table below. Table entries that are shaded gray are the default values for the corresponding GPIO pin.

Table 31-6 on page 2086 lists the signals based on number of possible pin assignments. This table can be used to plan how to configure the pins for a particular functionality. Application Note AN01274 Configuring Tiva™ C Series Microcontrollers with Pin Multiplexing provides an overview of the pin muxing implementation, an explanation of how a system designer defines a pin configuration, and examples of the pin configuration process.

Note: All digital inputs are Schmitt triggered.

31.1 Signals by Pin Number

Table 31-2. Signals by Pin Number

| Pin Number | Pin Name | Pin Type | Buffer Type | Description |
|------------|-----------|----------|-------------|--|
| A1 | GND | - | Power | Ground reference for logic and I/O pins. |
| A2 | GND | - | Power | Ground reference for logic and I/O pins. |
| A4 | PD4 | I/O | TTL | GPIO port D bit 4. |
| | AIN7 | I | Analog | Analog-to-digital converter input 7. |
| | SSI1XDAT2 | I/O | TTL | SSI Module 1 Bi-directional Data Pin 2. |
| | T3CCP0 | I/O | TTL | 16/32-Bit Timer 3 Capture/Compare/PWM 0. |
| | U2Rx | I | TTL | UART module 2 receive. |
| A5 | PE4 | I/O | TTL | GPIO port E bit 4. |
| | AIN9 | I | Analog | Analog-to-digital converter input 9. |
| | SSI1XDAT0 | I/O | TTL | SSI Module 1 Bi-directional Data Pin 0 (SSI1TX in Legacy SSI Mode). |
| | U1RI | I | TTL | UART module 1 Ring Indicator modem status input signal. |
| A7 | PE6 | I/O | TTL | GPIO port E bit 6. |
| | AIN20 | I | Analog | Analog-to-digital converter input 20. |
| | I2C9SCL | I/O | OD | I ² C module 9 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| | U0CTS | I | TTL | UART module 0 Clear To Send modem flow control input signal. |
| A8 | PP7 | I/O | TTL | GPIO port P bit 7. |
| | AIN22 | I | Analog | Analog-to-digital converter input 22. |
| | OWIRE | I/O | TTL | 1-Wire Single Bus Pin. This signal is input only if 1-Wire Alternate Output is enabled. |
| A10 | PN4 | I/O | TTL | GPIO port N bit 4. |
| | EPI0S34 | I/O | TTL | EPI module 0 signal 34. |
| | I2C2SDA | I/O | OD | I ² C module 2 data. |
| | U1DTR | O | TTL | UART module 1 Data Terminal Ready modem status input signal. |
| | U3RTS | O | TTL | UART module 3 Request to Send modem flow control output line. |
| A11 | PN2 | I/O | TTL | GPIO port N bit 2. |
| | EPI0S29 | I/O | TTL | EPI module 0 signal 29. |
| | U1DCD | I | TTL | UART module 1 Data Carrier Detect modem status input signal. |
| | U2RTS | O | TTL | UART module 2 Request to Send modem flow control output line. |
| A13 | PQ4 | I/O | TTL | GPIO port Q bit 4. |
| | DIVSCLK | O | TTL | An optionally divided reference clock output based on a selected clock source. Note that this signal is not synchronized to the System Clock. |
| | U1Rx | I | TTL | UART module 1 receive. |
| A14 | PS3 | I/O | TTL | GPIO port S bit 3. |
| | LCDDATA23 | O | TTL | LCD Data Pin 23 output. |
| | M0FAULT3 | I | TTL | Motion Control Module 0 PWM Fault 3. |
| | T3CCP1 | I/O | TTL | 16/32-Bit Timer 3 Capture/Compare/PWM 1. |

Table 31-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type | Description |
|------------|-----------|----------|-------------|---|
| A16 | PB0 | I/O | TTL | GPIO port B bit 0. |
| | CAN1Rx | I | TTL | CAN module 1 receive. |
| | I2C5SCL | I/O | OD | I ² C module 5 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| | T4CCP0 | I/O | TTL | 16/32-Bit Timer 4 Capture/Compare/PWM 0. |
| | U1Rx | I | TTL | UART module 1 receive. |
| | USB0ID | I | Analog | This signal senses the state of the USB ID signal. The USB PHY enables an integrated pull-up, and an external element (USB connector) indicates the initial state of the USB controller (pulled down is the A side of the cable and pulled up is the B side). |
| A17 | PB2 | I/O | TTL | GPIO port B bit 2. |
| | EN0MDC | O | TTL | Ethernet 0 Management Data Clock. |
| | EPI0S27 | I/O | TTL | EPI module 0 signal 27. |
| | I2C0SCL | I/O | OD | I ² C module 0 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| | T5CCP0 | I/O | TTL | 16/32-Bit Timer 5 Capture/Compare/PWM 0. |
| | USB0STP | O | TTL | Asserted by the USB controller to signal the end of a USB transmit packet or register write operation. |
| A18 | GND | - | Power | Ground reference for logic and I/O pins. |
| A19 | GND | - | Power | Ground reference for logic and I/O pins. |
| B1 | GND | - | Power | Ground reference for logic and I/O pins. |
| B2 | PD7 | I/O | TTL | GPIO port D bit 7. |
| | AIN4 | I | Analog | Analog-to-digital converter input 4. |
| | NMI | I | TTL | Non-maskable interrupt. |
| | SSI2XDAT2 | I/O | TTL | SSI Module 2 Bi-directional Data Pin 2. |
| | T4CCP1 | I/O | TTL | 16/32-Bit Timer 4 Capture/Compare/PWM 1. |
| | U2CTS | I | TTL | UART module 2 Clear To Send modem flow control input signal. |
| | USB0PFLT | I | TTL | Optionally used in Host mode by an external power source to indicate an error state by that power source. |
| B3 | PD6 | I/O | TTL | GPIO port D bit 6. |
| | AIN5 | I | Analog | Analog-to-digital converter input 5. |
| | SSI2XDAT3 | I/O | TTL | SSI Module 2 Bi-directional Data Pin 3. |
| | T4CCP0 | I/O | TTL | 16/32-Bit Timer 4 Capture/Compare/PWM 0. |
| | U2RTS | O | TTL | UART module 2 Request to Send modem flow control output line. |
| | USB0EPEN | O | TTL | Optionally used in Host mode to control an external power source to supply power to the USB bus. |
| B4 | PD5 | I/O | TTL | GPIO port D bit 5. |
| | AIN6 | I | Analog | Analog-to-digital converter input 6. |
| | SSI1XDAT3 | I/O | TTL | SSI Module 1 Bi-directional Data Pin 3. |
| | T3CCP1 | I/O | TTL | 16/32-Bit Timer 3 Capture/Compare/PWM 1. |
| | U2Tx | O | TTL | UART module 2 transmit. |

Table 31-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type | Description |
|------------|-----------|----------|-------------|--|
| B5 | PE5 | I/O | TTL | GPIO port E bit 5. |
| | AIN8 | I | Analog | Analog-to-digital converter input 8. |
| | SSI1XDAT1 | I/O | TTL | SSI Module 1 Bi-directional Data Pin 1 (SSI1RX in Legacy SSI Mode). |
| B6 | PB5 | I/O | TTL | GPIO port B bit 5. |
| | AIN11 | I | Analog | Analog-to-digital converter input 11. |
| | I2C5SDA | I/O | OD | I ² C module 5 data. |
| | SSI1Clk | I/O | TTL | SSI module 1 clock. |
| | U0RTS | O | TTL | UART module 0 Request to Send modem flow control output signal. |
| B7 | PE7 | I/O | TTL | GPIO port E bit 7. |
| | AIN21 | I | Analog | Analog-to-digital converter input 21. |
| | I2C9SDA | I/O | OD | I ² C module 9 data. |
| | NMI | I | TTL | Non-maskable interrupt. |
| | U0RTS | O | TTL | UART module 0 Request to Send modem flow control output signal. |
| B8 | PP6 | I/O | TTL | GPIO port P bit 6. |
| | AIN23 | I | Analog | Analog-to-digital converter input 23. |
| | I2C2SDA | I/O | OD | I ² C module 2 data. |
| | U1DCD | I | TTL | UART module 1 Data Carrier Detect modem status input signal. |
| B9 | PN5 | I/O | TTL | GPIO port N bit 5. |
| | EPI0S35 | I/O | TTL | EPI module 0 signal 35. |
| | I2C2SCL | I/O | OD | I ² C module 2 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| | U1RI | I | TTL | UART module 1 Ring Indicator modem status input signal. |
| | U3CTS | I | TTL | UART module 3 Clear To Send modem flow control input signal. |
| B10 | PN3 | I/O | TTL | GPIO port N bit 3. |
| | EPI0S30 | I/O | TTL | EPI module 0 signal 30. |
| | U1DSR | I | TTL | UART module 1 Data Set Ready modem output control line. |
| | U2CTS | I | TTL | UART module 2 Clear To Send modem flow control input signal. |
| B11 | PN1 | I/O | TTL | GPIO port N bit 1. |
| | U1CTS | I | TTL | UART module 1 Clear To Send modem flow control input signal. |
| B12 | PP5 | I/O | TTL | GPIO port P bit 5. |
| | I2C2SCL | I/O | OD | I ² C module 2 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| | OWALT | I/O | TTL | 1-Wire Optional 2nd signal to be used as output. |
| | U3CTS | I | TTL | UART module 3 Clear To Send modem flow control input signal. |
| | USB0D6 | I/O | TTL | USB data 6. |
| B13 | PP2 | I/O | TTL | GPIO port P bit 2. |
| | EPI0S29 | I/O | TTL | EPI module 0 signal 29. |
| | U0DTR | O | TTL | UART module 0 Data Terminal Ready modem status input signal. |
| | USB0NXT | O | TTL | Asserted by the external PHY to throttle all data types. |

Table 31-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type | Description |
|------------|-----------|----------|-------------|--|
| B14 | PS2 | I/O | TTL | GPIO port S bit 2. |
| | LCDDATA22 | O | TTL | LCD Data Pin 22 output. |
| | MOFAULT2 | I | TTL | Motion Control Module 0 PWM Fault 2. |
| | T3CCP0 | I/O | TTL | 16/32-Bit Timer 3 Capture/Compare/PWM 0. |
| | U1DSR | I | TTL | UART module 1 Data Set Ready modem output control line. |
| B15 | PC0 | I/O | TTL | GPIO port C bit 0. |
| | SWCLK | I | TTL | JTAG/SWD CLK. |
| | TCK | I | TTL | JTAG/SWD CLK. |
| B16 | PB1 | I/O | TTL | GPIO port B bit 1. |
| | CAN1Tx | O | TTL | CAN module 1 transmit. |
| | I2C5SDA | I/O | OD | I ² C module 5 data. |
| | T4CCP1 | I/O | TTL | 16/32-Bit Timer 4 Capture/Compare/PWM 1. |
| | U1Tx | O | TTL | UART module 1 transmit. |
| | USB0VBUS | I/O | Analog | This signal is used during the session request protocol. This signal allows the USB PHY to both sense the voltage level of VBUS, and pull up VBUS momentarily during VBUS pulsing. |
| B17 | PB3 | I/O | TTL | GPIO port B bit 3. |
| | EN0MDIO | I/O | TTL | Ethernet 0 Management Data Input/Output signal. |
| | EPI0S28 | I/O | TTL | EPI module 0 signal 28. |
| | I2C0SDA | I/O | OD | I ² C module 0 data. |
| | T5CCP1 | I/O | TTL | 16/32-Bit Timer 5 Capture/Compare/PWM 1. |
| | USB0CLK | O | TTL | 60-MHz clock to the external PHY. |
| B18 | PL7 | I/O | TTL | GPIO port L bit 7. |
| | T1CCP1 | I/O | TTL | 16/32-Bit Timer 1 Capture/Compare/PWM 1. |
| | USB0DM | I/O | Analog | Bidirectional differential data pin (D- per USB specification) for USB0. |
| B19 | GND | - | Power | Ground reference for logic and I/O pins. |
| C1 | PD1 | I/O | TTL | GPIO port D bit 1. |
| | AIN14 | I | Analog | Analog-to-digital converter input 14. |
| | C1o | O | TTL | Analog comparator 1 output. |
| | I2C7SDA | I/O | OD | I ² C module 7 data. |
| | SSI2XDAT0 | I/O | TTL | SSI Module 2 Bi-directional Data Pin 0 (SSI2TX in Legacy SSI Mode). |
| | T0CCP1 | I/O | TTL | 16/32-Bit Timer 0 Capture/Compare/PWM 1. |
| C2 | PD0 | I/O | TTL | GPIO port D bit 0. |
| | AIN15 | I | Analog | Analog-to-digital converter input 15. |
| | C0o | O | TTL | Analog comparator 0 output. |
| | I2C7SCL | I/O | OD | I ² C module 7 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| | SSI2XDAT1 | I/O | TTL | SSI Module 2 Bi-directional Data Pin 1 (SSI2RX in Legacy SSI Mode). |
| | T0CCP0 | I/O | TTL | 16/32-Bit Timer 0 Capture/Compare/PWM 0. |
| C5 | NC | - | - | No connect. Leave the pin electrically unconnected/isolated. |

Table 31-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type | Description |
|------------|----------|----------|-------------|---|
| C6 | PB4 | I/O | TTL | GPIO port B bit 4. |
| | AIN10 | I | Analog | Analog-to-digital converter input 10. |
| | I2C5SCL | I/O | OD | I ² C module 5 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| | SSI1Fss | I/O | TTL | SSI module 1 frame signal. |
| | U0CTS | I | TTL | UART module 0 Clear To Send modem flow control input signal. |
| C8 | PJ0 | I/O | TTL | GPIO port J bit 0. |
| | EN0PPS | O | TTL | Ethernet 0 Pulse-Per-Second (PPS) Output. |
| | U3Rx | I | TTL | UART module 3 receive. |
| C10 | PN0 | I/O | TTL | GPIO port N bit 0. |
| | U1RTS | O | TTL | UART module 1 Request to Send modem flow control output line. |
| C12 | PP3 | I/O | TTL | GPIO port P bit 3. |
| | EPI0S30 | I/O | TTL | EPI module 0 signal 30. |
| | RTCCLK | O | TTL | Buffered version of the Hibernation module's 32.768-kHz clock. This signal is not output when the part is in Hibernate mode and before being configured after power-on reset. |
| | U0DCD | I | TTL | UART module 0 Data Carrier Detect modem status input signal. |
| | U1CTS | I | TTL | UART module 1 Clear To Send modem flow control input signal. |
| | USB0DIR | O | TTL | Indicates that the external PHY is able to accept data from the USB controller. |
| C14 | PC3 | I/O | TTL | GPIO port C bit 3. |
| | SWO | O | TTL | JTAG TDO and SWO. |
| | TDO | O | TTL | JTAG TDO and SWO. |
| C15 | PC1 | I/O | TTL | GPIO port C bit 1. |
| | SWDIO | I/O | TTL | JTAG TMS and SWDIO. |
| | TMS | I | TTL | JTAG TMS and SWDIO. |
| C18 | PL6 | I/O | TTL | GPIO port L bit 6. |
| | T1CCP0 | I/O | TTL | 16/32-Bit Timer 1 Capture/Compare/PWM 0. |
| | USB0DP | I/O | Analog | Bidirectional differential data pin (D+ per USB specification) for USB0. |
| D1 | PD3 | I/O | TTL | GPIO port D bit 3. |
| | AIN12 | I | Analog | Analog-to-digital converter input 12. |
| | I2C8SDA | I/O | OD | I ² C module 8 data. |
| | SSI2Clk | I/O | TTL | SSI module 2 clock. |
| | T1CCP1 | I/O | TTL | 16/32-Bit Timer 1 Capture/Compare/PWM 1. |
| D2 | PD2 | I/O | TTL | GPIO port D bit 2. |
| | AIN13 | I | Analog | Analog-to-digital converter input 13. |
| | C2o | O | TTL | Analog comparator 2 output. |
| | I2C8SCL | I/O | OD | I ² C module 8 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| | SSI2Fss | I/O | TTL | SSI module 2 frame signal. |
| | T1CCP0 | I/O | TTL | 16/32-Bit Timer 1 Capture/Compare/PWM 0. |

Table 31-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type | Description |
|------------|-----------|----------|-------------|--|
| D6 | PP0 | I/O | TTL | GPIO port P bit 0. |
| | C2+ | I | Analog | Analog comparator 2 positive input. |
| | EN0INTRN | I | TTL | Ethernet 0 Interrupt from the Ethernet PHY. |
| | SSI3XDAT2 | I/O | TTL | SSI Module 3 Bi-directional Data Pin 2. |
| | T6CCP0 | I/O | TTL | 16/32-Bit Timer 6 Capture/Compare/PWM 0. |
| | U6Rx | I | TTL | UART module 6 receive. |
| D7 | PP1 | I/O | TTL | GPIO port P bit 1. |
| | C2- | I | Analog | Analog comparator 2 negative input. |
| | SSI3XDAT3 | I/O | TTL | SSI Module 3 Bi-directional Data Pin 3. |
| | T6CCP1 | I/O | TTL | 16/32-Bit Timer 6 Capture/Compare/PWM 1. |
| | U6Tx | O | TTL | UART module 6 transmit. |
| D8 | PP4 | I/O | TTL | GPIO port P bit 4. |
| | OWIRE | I/O | TTL | 1-Wire Single Bus Pin. This signal is input only if 1-Wire Alternate Output is enabled. |
| | U0DSR | I | TTL | UART module 0 Data Set Ready modem output control line. |
| | U3RTS | O | TTL | UART module 3 Request to Send modem flow control output line. |
| | USB0D7 | I/O | TTL | USB data 7. |
| D12 | PS0 | I/O | TTL | GPIO port S bit 0. |
| | LCDDATA20 | O | TTL | LCD Data Pin 20 output. |
| | M0FAULT0 | I | TTL | Motion Control Module 0 PWM Fault 0. |
| | T2CCP0 | I/O | TTL | 16/32-Bit Timer 2 Capture/Compare/PWM 0. |
| D13 | PS1 | I/O | TTL | GPIO port S bit 1. |
| | LCDDATA21 | O | TTL | LCD Data Pin 21 output. |
| | M0FAULT1 | I | TTL | Motion Control Module 0 PWM Fault 1. |
| | T2CCP1 | I/O | TTL | 16/32-Bit Timer 2 Capture/Compare/PWM 1. |
| D14 | PC2 | I/O | TTL | GPIO port C bit 2. |
| | TDI | I | TTL | JTAG TDI. |
| D18 | GNDX2 | - | Power | GND for the MOSC. When using a crystal clock source, this pin should be connected to digital ground along with the crystal load capacitors. When using an external oscillator, this pin should be connected to digital ground. |
| D19 | OSC1 | O | Analog | Main oscillator crystal output. Leave unconnected when using a single-ended clock source. |
| E2 | PQ1 | I/O | TTL | GPIO port Q bit 1. |
| | EPI0S21 | I/O | TTL | EPI module 0 signal 21. |
| | SSI3Fss | I/O | TTL | SSI module 3 frame signal. |
| | T6CCP1 | I/O | TTL | 16/32-Bit Timer 6 Capture/Compare/PWM 1. |
| E3 | PQ0 | I/O | TTL | GPIO port Q bit 0. |
| | EPI0S20 | I/O | TTL | EPI module 0 signal 20. |
| | SSI3Clk | I/O | TTL | SSI module 3 clock. |
| | T6CCP0 | I/O | TTL | 16/32-Bit Timer 6 Capture/Compare/PWM 0. |
| E7 | PJ1 | I/O | TTL | GPIO port J bit 1. |
| | U3Tx | O | TTL | UART module 3 transmit. |

Table 31-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type | Description |
|------------|-----------|----------|-------------|---|
| E10 | VDDC | - | Power | Positive supply for most of the logic function, including the processor core and most peripherals. The voltage on this pin is 1.2 V and is supplied by the on-chip LDO. The VDDC pins should only be connected to each other and an external capacitor as specified in Table 32-15 on page 2111 . |
| E13 | NC | - | - | No connect. Leave the pin electrically unconnected/isolated. |
| E17 | PJ5 | I/O | TTL | GPIO port J bit 5. |
| | LCDDATA17 | O | TTL | LCD Data Pin 17 output. |
| | U3CTS | I | TTL | UART module 3 Clear To Send modem flow control input signal. |
| E18 | PT2 | I/O | TTL | GPIO port T bit 2. |
| | CAN1Rx | I | TTL | CAN module 1 receive. |
| | LCDDATA18 | O | TTL | LCD Data Pin 18 output. |
| | T7CCP0 | I/O | TTL | 16/32-Bit Timer 7 Capture/Compare/PWM 0. |
| E19 | OSC0 | I | Analog | Main oscillator crystal input or an external clock reference input. |
| F1 | PB7 | I/O | TTL | GPIO port B bit 7. |
| | I2C6SDA | I/O | OD | I ² C module 6 data. |
| | T6CCP1 | I/O | TTL | 16/32-Bit Timer 6 Capture/Compare/PWM 1. |
| F2 | PB6 | I/O | TTL | GPIO port B bit 6. |
| | I2C6SCL | I/O | OD | I ² C module 6 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| | T6CCP0 | I/O | TTL | 16/32-Bit Timer 6 Capture/Compare/PWM 0. |
| F3 | VDDA | - | Power | The positive supply for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions. VDDA pins must be supplied with a voltage that meets the specification in , regardless of system implementation. |
| F4 | VREFA+ | - | Analog | A reference voltage used to specify the voltage at which the ADC converts to a maximum value. This pin is used in conjunction with VREFA-, which specifies the minimum value . The voltage that is applied to VREFA+ is the voltage with which an AIN _n signal is converted to 4095. The VREFA+ voltage is limited to the range specified in Table 32-44 on page 2138. |
| F10 | GND | - | Power | Ground reference for logic and I/O pins. |
| F16 | PJ3 | I/O | TTL | GPIO port J bit 3. |
| | LCDDATA15 | I/O | TTL | LCD Data Pin 15 input/output. |
| | U2CTS | I | TTL | UART module 2 Clear To Send modem flow control input signal. |
| F17 | PT3 | I/O | TTL | GPIO port T bit 3. |
| | CAN1Tx | O | TTL | CAN module 1 transmit. |
| | LCDDATA19 | O | TTL | LCD Data Pin 19 output. |
| | T7CCP1 | I/O | TTL | 16/32-Bit Timer 7 Capture/Compare/PWM 1. |
| F18 | PJ4 | I/O | TTL | GPIO port J bit 4. |
| | LCDDATA16 | O | TTL | LCD Data Pin 16 output. |
| | U3RTS | O | TTL | UART module 3 Request to Send modem flow control output line. |

Table 31-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type | Description |
|------------|----------|----------|-------------|--|
| G1 | PE2 | I/O | TTL | GPIO port E bit 2. |
| | AIN1 | I | Analog | Analog-to-digital converter input 1. |
| | U1DCD | I | TTL | UART module 1 Data Carrier Detect modem status input signal. |
| G2 | PE3 | I/O | TTL | GPIO port E bit 3. |
| | AIN0 | I | Analog | Analog-to-digital converter input 0. |
| | OWIRE | I/O | TTL | 1-Wire Single Bus Pin. This signal is input only if 1-Wire Alternate Output is enabled. |
| | U1DTR | O | TTL | UART module 1 Data Terminal Ready modem status input signal. |
| G4 | GNDA | - | Power | The ground reference for the analog circuits (ADC, Analog Comparators, etc.). These are separated from GND to minimize the electrical noise contained on VDD from affecting the analog functions. |
| G5 | VREFA- | - | Analog | A reference voltage used to specify the input voltage at which the ADC converts to a minimum value. This pin is used in conjunction with VREFA+, which specifies the maximum value. In other words, the voltage that is applied to VREFA- is the voltage with which an AINn signal is converted to 0, while the voltage that is applied to VREFA+ is the voltage with which an AINn signal is converted to 4095. The VREFA- voltage is limited to the range specified in Table 32-44 on page 2138. |
| G10 | VDD | - | Power | Positive supply for I/O and some logic. |
| G15 | PM5 | I/O | TTL | GPIO port M bit 5. |
| | T4CCP1 | I/O | TTL | 16/32-Bit Timer 4 Capture/Compare/PWM 1. |
| | TMPR2 | I/O | TTL | Tamper signal 2. |
| | U0DCD | I | TTL | UART module 0 Data Carrier Detect modem status input signal. |
| G16 | PL0 | I/O | TTL | GPIO port L bit 0. |
| | EPI0S16 | I/O | TTL | EPI module 0 signal 16. |
| | I2C2SDA | I/O | OD | I ² C module 2 data. |
| | M0FAULT3 | I | TTL | Motion Control Module 0 PWM Fault 3. |
| | USB0D0 | I/O | TTL | USB data 0. |
| G18 | PL2 | I/O | TTL | GPIO port L bit 2. |
| | COo | O | TTL | Analog comparator 0 output. |
| | EPI0S18 | I/O | TTL | EPI module 0 signal 18. |
| | PhB0 | I | TTL | QEI module 0 phase B. |
| | USB0D2 | I/O | TTL | USB data 2. |
| G19 | PL5 | I/O | TTL | GPIO port L bit 5. |
| | EPI0S33 | I/O | TTL | EPI module 0 signal 33. |
| | T0CCP1 | I/O | TTL | 16/32-Bit Timer 0 Capture/Compare/PWM 1. |
| | USB0D5 | I/O | TTL | USB data 5. |
| H2 | PE1 | I/O | TTL | GPIO port E bit 1. |
| | AIN2 | I | Analog | Analog-to-digital converter input 2. |
| | U1DSR | I | TTL | UART module 1 Data Set Ready modem output control line. |
| H3 | PE0 | I/O | TTL | GPIO port E bit 0. |
| | AIN3 | I | Analog | Analog-to-digital converter input 3. |
| | U1RTS | O | TTL | UART module 1 Request to Send modem flow control output line. |

Table 31-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type | Description |
|------------|-----------|----------|-------------|---|
| H4 | PQ2 | I/O | TTL | GPIO port Q bit 2. |
| | EPI0S22 | I/O | TTL | EPI module 0 signal 22. |
| | SSI3XDAT0 | I/O | TTL | SSI Module 3 Bi-directional Data Pin 0 (SSI3TX in Legacy SSI Mode). |
| | T7CCP0 | I/O | TTL | 16/32-Bit Timer 7 Capture/Compare/PWM 0. |
| H9 | VDD | - | Power | Positive supply for I/O and some logic. |
| H10 | GND | - | Power | Ground reference for logic and I/O pins. |
| H11 | GND | - | Power | Ground reference for logic and I/O pins. |
| H12 | GND | - | Power | Ground reference for logic and I/O pins. |
| H16 | VDDC | - | Power | Positive supply for most of the logic function, including the processor core and most peripherals. The voltage on this pin is 1.2 V and is supplied by the on-chip LDO. The VDDC pins should only be connected to each other and an external capacitor as specified in Table 32-15 on page 2111 . |
| H17 | PJ2 | I/O | TTL | GPIO port J bit 2. |
| | LCDDATA14 | I/O | TTL | LCD Data Pin 14 input/output. |
| | U2RTS | O | TTL | UART module 2 Request to Send modem flow control output line. |
| H18 | PL4 | I/O | TTL | GPIO port L bit 4. |
| | EPI0S26 | I/O | TTL | EPI module 0 signal 26. |
| | T0CCP0 | I/O | TTL | 16/32-Bit Timer 0 Capture/Compare/PWM 0. |
| | USB0D4 | I/O | TTL | USB data 4. |
| H19 | PL1 | I/O | TTL | GPIO port L bit 1. |
| | EPI0S17 | I/O | TTL | EPI module 0 signal 17. |
| | I2C2SCL | I/O | OD | I ² C module 2 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| | PhA0 | I | TTL | QEI module 0 phase A. |
| | USB0D1 | I/O | TTL | USB data 1. |
| J1 | PK0 | I/O | TTL | GPIO port K bit 0. |
| | AIN16 | I | Analog | Analog-to-digital converter input 16. |
| | EPI0S0 | I/O | TTL | EPI module 0 signal 0. |
| | U4Rx | I | TTL | UART module 4 receive. |
| J2 | PK1 | I/O | TTL | GPIO port K bit 1. |
| | AIN17 | I | Analog | Analog-to-digital converter input 17. |
| | EPI0S1 | I/O | TTL | EPI module 0 signal 1. |
| | U4Tx | O | TTL | UART module 4 transmit. |
| J8 | VDD | - | Power | Positive supply for I/O and some logic. |
| J9 | VDD | - | Power | Positive supply for I/O and some logic. |
| J10 | VDD | - | Power | Positive supply for I/O and some logic. |
| J11 | GND | - | Power | Ground reference for logic and I/O pins. |
| J12 | GND | - | Power | Ground reference for logic and I/O pins. |

Table 31-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type | Description |
|------------|-----------|----------|-------------|---|
| J18 | PL3 | I/O | TTL | GPIO port L bit 3. |
| | C1o | O | TTL | Analog comparator 1 output. |
| | EPI0S19 | I/O | TTL | EPI module 0 signal 19. |
| | IDX0 | I | TTL | QEI module 0 index. |
| | USB0D3 | I/O | TTL | USB data 3. |
| K1 | PK2 | I/O | TTL | GPIO port K bit 2. |
| | AIN18 | I | Analog | Analog-to-digital converter input 18. |
| | EPI0S2 | I/O | TTL | EPI module 0 signal 2. |
| | U4RTS | O | TTL | UART module 4 Request to Send modem flow control output line. |
| K2 | PK3 | I/O | TTL | GPIO port K bit 3. |
| | AIN19 | I | Analog | Analog-to-digital converter input 19. |
| | EPI0S3 | I/O | TTL | EPI module 0 signal 3. |
| | U4CTS | I | TTL | UART module 4 Clear To Send modem flow control input signal. |
| K3 | PC7 | I/O | TTL | GPIO port C bit 7. |
| | C0- | I | Analog | Analog comparator 0 negative input. |
| | EPI0S4 | I/O | TTL | EPI module 0 signal 4. |
| | U5Tx | O | TTL | UART module 5 transmit. |
| K5 | PJ7 | I/O | TTL | GPIO port J bit 7. |
| | U4CTS | I | TTL | UART module 4 Clear To Send modem flow control input signal. |
| K6 | GND | - | Power | Ground reference for logic and I/O pins. |
| K7 | VDD | - | Power | Positive supply for I/O and some logic. |
| K8 | VDD | - | Power | Positive supply for I/O and some logic. |
| K9 | GND | - | Power | Ground reference for logic and I/O pins. |
| K10 | GND | - | Power | Ground reference for logic and I/O pins. |
| K11 | VDD | - | Power | Positive supply for I/O and some logic. |
| K12 | VDD | - | Power | Positive supply for I/O and some logic. |
| K13 | GND | - | Power | Ground reference for logic and I/O pins. |
| K14 | GND | - | Power | Ground reference for logic and I/O pins. |
| K15 | PG5 | I/O | TTL | GPIO port G bit 5. |
| | EN0TXD1 | O | TTL | Ethernet 0 Transmit Data 1. |
| | I2C3SDA | I/O | OD | I ² C module 3 data. |
| | OWALT | I/O | TTL | 1-Wire Optional 2nd signal to be used as output. |
| | SSI2XDAT0 | I/O | TTL | SSI Module 2 Bi-directional Data Pin 0 (SSI2TX in Legacy SSI Mode). |
| | U0RTS | O | TTL | UART module 0 Request to Send modem flow control output signal. |

Table 31-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type | Description |
|------------|-----------|----------|-------------|---|
| K17 | PG4 | I/O | TTL | GPIO port G bit 4. |
| | EN0TXD0 | O | TTL | Ethernet 0 Transmit Data 0. |
| | I2C3SCL | I/O | OD | I ² C module 3 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| | OWIRE | I/O | TTL | 1-Wire Single Bus Pin. This signal is input only if 1-Wire Alternate Output is enabled. |
| | SSI2XDAT1 | I/O | TTL | SSI Module 2 Bi-directional Data Pin 1 (SSI2RX in Legacy SSI Mode). |
| | U0CTS | I | TTL | UART module 0 Clear To Send modem flow control input signal. |
| K18 | PM0 | I/O | TTL | GPIO port M bit 0. |
| | EPI0S15 | I/O | TTL | EPI module 0 signal 15. |
| | T2CCP0 | I/O | TTL | 16/32-Bit Timer 2 Capture/Compare/PWM 0. |
| K19 | PM1 | I/O | TTL | GPIO port M bit 1. |
| | EPI0S14 | I/O | TTL | EPI module 0 signal 14. |
| | T2CCP1 | I/O | TTL | 16/32-Bit Timer 2 Capture/Compare/PWM 1. |
| L2 | PC6 | I/O | TTL | GPIO port C bit 6. |
| | C0+ | I | Analog | Analog comparator 0 positive input. |
| | EPI0S5 | I/O | TTL | EPI module 0 signal 5. |
| | U5Rx | I | TTL | UART module 5 receive. |
| L8 | GND | - | Power | Ground reference for logic and I/O pins. |
| L9 | GND | - | Power | Ground reference for logic and I/O pins. |
| L10 | VDD | - | Power | Positive supply for I/O and some logic. |
| L11 | VDD | - | Power | Positive supply for I/O and some logic. |
| L12 | VDD | - | Power | Positive supply for I/O and some logic. |
| L18 | PM2 | I/O | TTL | GPIO port M bit 2. |
| | EPI0S13 | I/O | TTL | EPI module 0 signal 13. |
| | T3CCP0 | I/O | TTL | 16/32-Bit Timer 3 Capture/Compare/PWM 0. |
| L19 | PM3 | I/O | TTL | GPIO port M bit 3. |
| | EPI0S12 | I/O | TTL | EPI module 0 signal 12. |
| | T3CCP1 | I/O | TTL | 16/32-Bit Timer 3 Capture/Compare/PWM 1. |
| M1 | PC5 | I/O | TTL | GPIO port C bit 5. |
| | C1+ | I | Analog | Analog comparator 1 positive input. |
| | EPI0S6 | I/O | TTL | EPI module 0 signal 6. |
| | RTCCLK | O | TTL | Buffered version of the Hibernation module's 32.768-kHz clock. This signal is not output when the part is in Hibernate mode and before being configured after power-on reset. |
| | T7CCP1 | I/O | TTL | 16/32-Bit Timer 7 Capture/Compare/PWM 1. |
| | U7Tx | O | TTL | UART module 7 transmit. |
| M2 | PC4 | I/O | TTL | GPIO port C bit 4. |
| | C1- | I | Analog | Analog comparator 1 negative input. |
| | EPI0S7 | I/O | TTL | EPI module 0 signal 7. |
| | T7CCP0 | I/O | TTL | 16/32-Bit Timer 7 Capture/Compare/PWM 0. |
| | U7Rx | I | TTL | UART module 7 receive. |

Table 31-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type | Description |
|------------|-------------|----------|-------------|--|
| M3 | PQ7 | I/O | TTL | GPIO port Q bit 7. |
| | U1RI | I | TTL | UART module 1 Ring Indicator modem status input signal. |
| M4 | PQ3 | I/O | TTL | GPIO port Q bit 3. |
| | EPI0S23 | I/O | TTL | EPI module 0 signal 23. |
| | SSI3XDAT1 | I/O | TTL | SSI Module 3 Bi-directional Data Pin 1 (SSI3RX in Legacy SSI Mode). |
| | T7CCP1 | I/O | TTL | 16/32-Bit Timer 7 Capture/Compare/PWM 1. |
| M8 | GND | - | Power | Ground reference for logic and I/O pins. |
| M9 | GND | - | Power | Ground reference for logic and I/O pins. |
| M10 | GND | - | Power | Ground reference for logic and I/O pins. |
| M11 | VDD | - | Power | Positive supply for I/O and some logic. |
| M12 | VDD | - | Power | Positive supply for I/O and some logic. |
| M16 | PG3 | I/O | TTL | GPIO port G bit 3. |
| | EN0TXEN | O | TTL | Ethernet 0 Transmit Enable. |
| | I2C2SDA | I/O | OD | I ² C module 2 data. |
| | SSI2XDAT2 | I/O | TTL | SSI Module 2 Bi-directional Data Pin 2. |
| M17 | HIB | O | TTL | An output that indicates the processor is in Hibernate mode. |
| M18 | PM4 | I/O | TTL | GPIO port M bit 4. |
| | EN0RREF_CLK | I/O | TTL | Ethernet 0 Reference Clock. |
| | T4CCP0 | I/O | TTL | 16/32-Bit Timer 4 Capture/Compare/PWM 0. |
| | TMPR3 | I/O | TTL | Tamper signal 3. |
| | U0CTS | I | TTL | UART module 0 Clear To Send modem flow control input signal. |
| N1 | PJ6 | I/O | TTL | GPIO port J bit 6. |
| | LCDAC | O | TTL | LCD AC bias or latch enable in Raster mode; Primary chip select (CS0)/Primary Enable (E0) in LIDD MPU/Hitachi mode |
| | U4RTS | O | TTL | UART module 4 Request to Send modem flow control output line. |
| N2 | PR2 | I/O | TTL | GPIO port R bit 2. |
| | I2C2SCL | I/O | OD | I ² C module 2 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| | LCDLP | O | TTL | LCD Line Clock or HSYNC in Raster mode; Write Strobe or Direction bit in LIDD mode |
| | M0PWM2 | O | TTL | Motion Control Module 0 PWM 2. This signal is controlled by Module 0 PWM Generator 1. |
| N4 | PR1 | I/O | TTL | GPIO port R bit 1. |
| | I2C1SDA | I/O | OD | I ² C module 1 data. |
| | LCDFP | O | TTL | LCD Frame Clock or VSYNC in Raster mode; Address Latch Enable in LIDD mode |
| | M0PWM1 | O | TTL | Motion Control Module 0 PWM 1. This signal is controlled by Module 0 PWM Generator 0. |
| | U4Rx | I | TTL | UART module 4 receive. |

Table 31-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type | Description |
|------------|-----------|----------|-------------|--|
| N5 | PR0 | I/O | TTL | GPIO port R bit 0. |
| | I2C1SCL | I/O | OD | I ² C module 1 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| | LCDCP | O | TTL | LCD Pixel Clock in Raster mode; read strobe or read/write strobe in LIDD mode |
| | M0PWM0 | O | TTL | Motion Control Module 0 PWM 0. This signal is controlled by Module 0 PWM Generator 0. |
| | U4Tx | O | TTL | UART module 4 transmit. |
| N10 | GND | - | Power | Ground reference for logic and I/O pins. |
| N15 | PG0 | I/O | TTL | GPIO port G bit 0. |
| | EN0PPS | O | TTL | Ethernet 0 Pulse-Per-Second (PPS) Output. |
| | EPI0S11 | I/O | TTL | EPI module 0 signal 11. |
| | I2C1SCL | I/O | OD | I ² C module 1 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| | M0PWM4 | O | TTL | Motion Control Module 0 PWM 4. This signal is controlled by Module 0 PWM Generator 2. |
| N16 | VDD | - | Power | Positive supply for I/O and some logic. |
| N18 | PM7 | I/O | TTL | GPIO port M bit 7. |
| | EN0COL | I | TTL | Ethernet 0 Collision Detect. |
| | T5CCP1 | I/O | TTL | 16/32-Bit Timer 5 Capture/Compare/PWM 1. |
| | TMPR0 | I/O | TTL | Tamper signal 0. |
| | U0RI | I | TTL | UART module 0 Ring Indicator modem status input signal. |
| N19 | PM6 | I/O | TTL | GPIO port M bit 6. |
| | EN0CRS | I | TTL | Ethernet 0 Carrier Sense. |
| | T5CCP0 | I/O | TTL | 16/32-Bit Timer 5 Capture/Compare/PWM 0. |
| | TMPR1 | I/O | TTL | Tamper signal 1. |
| | U0DSR | I | TTL | UART module 0 Data Set Ready modem output control line. |
| P2 | PR5 | I/O | TTL | GPIO port R bit 5. |
| | I2C3SDA | I/O | OD | I ² C module 3 data. |
| | LCDDATA01 | I/O | TTL | LCD Data Pin 1 input/output. |
| | M0PWM5 | O | TTL | Motion Control Module 0 PWM 5. This signal is controlled by Module 0 PWM Generator 2. |
| | T0CCP1 | I/O | TTL | 16/32-Bit Timer 0 Capture/Compare/PWM 1. |
| | U1Rx | I | TTL | UART module 1 receive. |
| P3 | PR4 | I/O | TTL | GPIO port R bit 4. |
| | I2C3SCL | I/O | OD | I ² C module 3 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| | LCDDATA00 | I/O | TTL | LCD Data Pin 0 input/output. |
| | M0PWM4 | O | TTL | Motion Control Module 0 PWM 4. This signal is controlled by Module 0 PWM Generator 2. |
| | T0CCP0 | I/O | TTL | 16/32-Bit Timer 0 Capture/Compare/PWM 0. |
| P4 | PH0 | I/O | TTL | GPIO port H bit 0. |
| | EPI0S0 | I/O | TTL | EPI module 0 signal 0. |
| | U0RTS | O | TTL | UART module 0 Request to Send modem flow control output signal. |

Table 31-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type | Description |
|------------|-----------|----------|---|--|
| P10 | VDD | - | Power | Positive supply for I/O and some logic. |
| P16 | GND | - | Power | Ground reference for logic and I/O pins. |
| P17 | VDD | - | Power | Positive supply for I/O and some logic. |
| P18 | RST | I | TTL | System reset input. |
| P19 | VBAT | - | Power | Power source for the Hibernation module. It is normally connected to the positive terminal of a battery and serves as the battery backup/Hibernation module power-source supply. |
| R1 | PH2 | I/O | TTL | GPIO port H bit 2. |
| | EPI0S2 | I/O | TTL | EPI module 0 signal 2. |
| | U0DCD | I | TTL | UART module 0 Data Carrier Detect modem status input signal. |
| R2 | PH1 | I/O | TTL | GPIO port H bit 1. |
| | EPI0S1 | I/O | TTL | EPI module 0 signal 1. |
| | U0CTS | I | TTL | UART module 0 Clear To Send modem flow control input signal. |
| R3 | PH4 | I/O | TTL | GPIO port H bit 4. |
| | U0DTR | O | TTL | UART module 0 Data Terminal Ready modem status input signal. |
| R7 | PA7 | I/O | TTL | GPIO port A bit 7. |
| | EPI0S9 | I/O | TTL | EPI module 0 signal 9. |
| | I2C6SDA | I/O | OD | I ² C module 6 data. |
| | SSI0XDAT3 | I/O | TTL | SSI Module 0 Bi-directional Data Pin 3. |
| | T3CCP1 | I/O | TTL | 16/32-Bit Timer 3 Capture/Compare/PWM 1. |
| | U2Tx | O | TTL | UART module 2 transmit. |
| | USB0EPEN | O | TTL | Optionally used in Host mode to control an external power source to supply power to the USB bus. |
| USB0PFLT | I | TTL | Optionally used in Host mode by an external power source to indicate an error state by that power source. | |
| R10 | PR7 | I/O | TTL | GPIO port R bit 7. |
| | EN0TXEN | O | TTL | Ethernet 0 Transmit Enable. |
| | I2C4SDA | I/O | OD | I ² C module 4 data. |
| | LCDDATA05 | I/O | TTL | LCD Data Pin 5 input/output. |
| | M0PWM7 | O | TTL | Motion Control Module 0 PWM 7. This signal is controlled by Module 0 PWM Generator 3. |
| | T1CCP1 | I/O | TTL | 16/32-Bit Timer 1 Capture/Compare/PWM 1. |
| R13 | PS7 | I/O | TTL | GPIO port S bit 7. |
| | EN0RXDV | I | TTL | Ethernet 0 Receive Data Valid. |
| | LCDDATA09 | I/O | TTL | LCD Data Pin 9 input/output. |
| | T5CCP1 | I/O | TTL | 16/32-Bit Timer 5 Capture/Compare/PWM 1. |
| R17 | GND | - | Power | Ground reference for logic and I/O pins. |
| R18 | GNDX | - | Power | GND for the Hibernation oscillator. When using a crystal clock source, this pin should be connected to digital ground along with the crystal load capacitors. When using an external oscillator, this pin should be connected to digital ground. |
| T1 | PH3 | I/O | TTL | GPIO port H bit 3. |
| | EPI0S3 | I/O | TTL | EPI module 0 signal 3. |
| | U0DSR | I | TTL | UART module 0 Data Set Ready modem output control line. |

Table 31-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type | Description |
|------------|-----------|----------|-------------|---|
| T2 | PH5 | I/O | TTL | GPIO port H bit 5. |
| | EN0PPS | O | TTL | Ethernet 0 Pulse-Per-Second (PPS) Output. |
| | U0RI | I | TTL | UART module 0 Ring Indicator modem status input signal. |
| T6 | PA2 | I/O | TTL | GPIO port A bit 2. |
| | I2C8SCL | I/O | OD | I ² C module 8 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| | SSI0Clk | I/O | TTL | SSI module 0 clock |
| | T1CCP0 | I/O | TTL | 16/32-Bit Timer 1 Capture/Compare/PWM 0. |
| | U4Rx | I | TTL | UART module 4 receive. |
| T7 | PF3 | I/O | TTL | GPIO port F bit 3. |
| | EN0MDIO | I/O | TTL | Ethernet 0 Management Data Input/Output signal. |
| | M0PWM3 | O | TTL | Motion Control Module 0 PWM 3. This signal is controlled by Module 0 PWM Generator 1. |
| | SSI3Clk | I/O | TTL | SSI module 3 clock. |
| | TRCLK | O | TTL | Trace clock. |
| T8 | PF6 | I/O | TTL | GPIO port F bit 6. |
| | LCDMCLK | O | TTL | LCD Memory Clock/Secondary chip Select (CS1)/Secondary Enable (E1) in LIDD Synchronous/Async MPU/Hitachi mode |
| T12 | PN6 | I/O | TTL | GPIO port N bit 6. |
| | EN0TXER | O | TTL | Ethernet 0 transmit error. |
| | LCDDATA13 | I/O | TTL | LCD Data Pin 13 input/output. |
| | U4RTS | O | TTL | UART module 4 Request to Send modem flow control output line. |
| T13 | PS5 | I/O | TTL | GPIO port S bit 5. |
| | EN0TXD1 | O | TTL | Ethernet 0 Transmit Data 1. |
| | LCDDATA07 | I/O | TTL | LCD Data Pin 7 input/output. |
| | PhB0 | I | TTL | QEI module 0 phase B. |
| | T4CCP1 | I/O | TTL | 16/32-Bit Timer 4 Capture/Compare/PWM 1. |
| T14 | PG1 | I/O | TTL | GPIO port G bit 1. |
| | EPI0S10 | I/O | TTL | EPI module 0 signal 10. |
| | I2C1SDA | I/O | OD | I ² C module 1 data. |
| | M0PWM5 | O | TTL | Motion Control Module 0 PWM 5. This signal is controlled by Module 0 PWM Generator 2. |
| T18 | XOSC0 | I | Analog | Hibernation module oscillator crystal input or an external clock reference input. Note that this is either a crystal or a 32.768-kHz oscillator for the Hibernation module RTC. |
| T19 | XOSC1 | O | Analog | Hibernation module oscillator crystal output. Leave unconnected when using a single-ended clock source. |
| U2 | PH6 | I/O | TTL | GPIO port H bit 6. |
| | U5Rx | I | TTL | UART module 5 receive. |
| | U7Rx | I | TTL | UART module 7 receive. |

Table 31-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type | Description |
|------------|--------------------------|----------|---|--|
| U5 | PA3 | I/O | TTL | GPIO port A bit 3. |
| | I2C8SDA | I/O | OD | I ² C module 8 data. |
| | SSI0Fss | I/O | TTL | SSI module 0 frame signal |
| | T1CCP1 | I/O | TTL | 16/32-Bit Timer 1 Capture/Compare/PWM 1. |
| | U4Tx | O | TTL | UART module 4 transmit. |
| U6 | PF0 | I/O | TTL | GPIO port F bit 0. |
| | EN0LED0 | O | TTL | Ethernet 0 LED 0. |
| | M0PWM0 | O | TTL | Motion Control Module 0 PWM 0. This signal is controlled by Module 0 PWM Generator 0. |
| | SSI3XDAT1 | I/O | TTL | SSI Module 3 Bi-directional Data Pin 1 (SSI3RX in Legacy SSI Mode). |
| U8 | TRD2 | O | TTL | Trace data 2. |
| | PF7 | I/O | TTL | GPIO port F bit 7. |
| U10 | LCDDATA02 | I/O | TTL | LCD Data Pin 2 input/output. |
| | PS6 | I/O | TTL | GPIO port S bit 6. |
| | EN0RXER | I | TTL | Ethernet 0 Receive Error. |
| | IDX0 | I | TTL | QEI module 0 index. |
| | LCDDATA08 | I/O | TTL | LCD Data Pin 8 input/output. |
| U12 | T5CCP0 | I/O | TTL | 16/32-Bit Timer 5 Capture/Compare/PWM 0. |
| | PN7 | I/O | TTL | GPIO port N bit 7. |
| | LCDDATA12 | I/O | TTL | LCD Data Pin 12 input/output. |
| | U1RTS | O | TTL | UART module 1 Request to Send modem flow control output line. |
| U14 | U4CTS | I | TTL | UART module 4 Clear To Send modem flow control input signal. |
| | PG7 | I/O | TTL | GPIO port G bit 7. |
| | EN0RXDV | I | TTL | Ethernet 0 Receive Data Valid. |
| | I2C4SDA | I/O | OD | I ² C module 4 data. |
| | OWIRE | I/O | TTL | 1-Wire Single Bus Pin. This signal is input only if 1-Wire Alternate Output is enabled. |
| U15 | SSI2C1k | I/O | TTL | SSI module 2 clock. |
| | PQ6 | I/O | TTL | GPIO port Q bit 6. |
| | EN0RXD1 | I | TTL | Ethernet 0 Receive Data 1. |
| U18 | U1DTR | O | TTL | UART module 1 Data Terminal Ready modem status input signal. |
| | $\overline{\text{WAKE}}$ | I | TTL | An external input that brings the processor out of Hibernate mode when asserted. |
| U19 | PK4 | I/O | TTL | GPIO port K bit 4. |
| | EN0INTRN | I | TTL | Ethernet 0 Interrupt from the Ethernet PHY. |
| | EN0LED0 | O | TTL | Ethernet 0 LED 0. |
| | EN0RXD3 | I | TTL | Ethernet 0 Receive Data 3. |
| | EPI0S32 | I/O | TTL | EPI module 0 signal 32. |
| | I2C3SCL | I/O | OD | I ² C module 3 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| M0PWM6 | O | TTL | Motion Control Module 0 PWM 6. This signal is controlled by Module 0 PWM Generator 3. | |

Table 31-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type | Description |
|------------|-----------|----------|-------------|--|
| V1 | GND | - | Power | Ground reference for logic and I/O pins. |
| V2 | PH7 | I/O | TTL | GPIO port H bit 7. |
| | U5Tx | O | TTL | UART module 5 transmit. |
| | U7Tx | O | TTL | UART module 7 transmit. |
| V3 | PA0 | I/O | TTL | GPIO port A bit 0. |
| | CAN0Rx | I | TTL | CAN module 0 receive. |
| | I2C9SCL | I/O | OD | I ² C module 9 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| | T0CCP0 | I/O | TTL | 16/32-Bit Timer 0 Capture/Compare/PWM 0. |
| | U0Rx | I | TTL | UART module 0 receive. |
| V4 | PA4 | I/O | TTL | GPIO port A bit 4. |
| | I2C7SCL | I/O | OD | I ² C module 7 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| | SSI0XDAT0 | I/O | TTL | SSI Module 0 Bi-directional Data Pin 0 (SSI0TX in Legacy SSI Mode). |
| | T2CCP0 | I/O | TTL | 16/32-Bit Timer 2 Capture/Compare/PWM 0. |
| | U3Rx | I | TTL | UART module 3 receive. |
| V5 | PA6 | I/O | TTL | GPIO port A bit 6. |
| | EN0RXCK | I | TTL | Ethernet 0 Receive Clock. |
| | EPI0S8 | I/O | TTL | EPI module 0 signal 8. |
| | I2C6SCL | I/O | OD | I ² C module 6 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| | SSI0XDAT2 | I/O | TTL | SSI Module 0 Bi-directional Data Pin 2. |
| | T3CCP0 | I/O | TTL | 16/32-Bit Timer 3 Capture/Compare/PWM 0. |
| | U2Rx | I | TTL | UART module 2 receive. |
| | USB0EPEN | O | TTL | Optionally used in Host mode to control an external power source to supply power to the USB bus. |
| V6 | PF1 | I/O | TTL | GPIO port F bit 1. |
| | EN0LED2 | O | TTL | Ethernet 0 LED 2. |
| | M0PWM1 | O | TTL | Motion Control Module 0 PWM 1. This signal is controlled by Module 0 PWM Generator 0. |
| | SSI3XDAT0 | I/O | TTL | SSI Module 3 Bi-directional Data Pin 0 (SSI3TX in Legacy SSI Mode). |
| | TRD1 | O | TTL | Trace data 1. |
| V7 | PF4 | I/O | TTL | GPIO port F bit 4. |
| | EN0LED1 | O | TTL | Ethernet 0 LED 1. |
| | M0FAULT0 | I | TTL | Motion Control Module 0 PWM Fault 0. |
| | SSI3XDAT2 | I/O | TTL | SSI Module 3 Bi-directional Data Pin 2. |
| | TRD3 | O | TTL | Trace data 3. |
| V8 | PR3 | I/O | TTL | GPIO port R bit 3. |
| | I2C2SDA | I/O | OD | I ² C module 2 data. |
| | LCDDATA03 | I/O | TTL | LCD Data Pin 3 input/output. |
| | M0PWM3 | O | TTL | Motion Control Module 0 PWM 3. This signal is controlled by Module 0 PWM Generator 1. |

Table 31-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type | Description |
|------------|-----------|----------|-------------|--|
| V9 | PS4 | I/O | TTL | GPIO port S bit 4. |
| | EN0TXD0 | O | TTL | Ethernet 0 Transmit Data 0. |
| | LCDDATA06 | I/O | TTL | LCD Data Pin 6 input/output. |
| | PhA0 | I | TTL | QEI module 0 phase A. |
| | T4CCP0 | I/O | TTL | 16/32-Bit Timer 4 Capture/Compare/PWM 0. |
| V10 | PT1 | I/O | TTL | GPIO port T bit 1. |
| | CAN0Tx | O | TTL | CAN module 0 transmit. |
| | EN0RXD1 | I | TTL | Ethernet 0 Receive Data 1. |
| | LCDDATA11 | I/O | TTL | LCD Data Pin 11 input/output. |
| | T6CCP1 | I/O | TTL | 16/32-Bit Timer 6 Capture/Compare/PWM 1. |
| V11 | PG2 | I/O | TTL | GPIO port G bit 2. |
| | EN0TXCK | I | TTL | Ethernet 0 Transmit Clock. |
| | I2C2SCL | I/O | OD | I ² C module 2 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| | SSI2XDAT3 | I/O | TTL | SSI Module 2 Bi-directional Data Pin 3. |
| V12 | PG6 | I/O | TTL | GPIO port G bit 6. |
| | EN0RXER | I | TTL | Ethernet 0 Receive Error. |
| | I2C4SCL | I/O | OD | I ² C module 4 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| | OWIRE | I/O | TTL | 1-Wire Single Bus Pin. This signal is input only if 1-Wire Alternate Output is enabled. |
| | SSI2Fss | I/O | TTL | SSI module 2 frame signal. |
| V13 | EN0RXIN | I/O | TTL | Ethernet PHY negative receive differential input. |
| V14 | EN0TXON | I/O | TTL | Ethernet PHY negative transmit differential output. |
| V15 | EN0TXOP | I/O | TTL | Ethernet PHY positive transmit differential output. |
| V16 | PK6 | I/O | TTL | GPIO port K bit 6. |
| | EN0LED1 | O | TTL | Ethernet 0 LED 1. |
| | EN0TXD2 | O | TTL | Ethernet 0 Transmit Data 2. |
| | EPI0S25 | I/O | TTL | EPI module 0 signal 25. |
| | I2C4SCL | I/O | OD | I ² C module 4 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| | MOFAULT1 | I | TTL | Motion Control Module 0 PWM Fault 1. |
| V17 | PK5 | I/O | TTL | GPIO port K bit 5. |
| | EN0LED2 | O | TTL | Ethernet 0 LED 2. |
| | EN0RXD2 | I | TTL | Ethernet 0 Receive Data 2. |
| | EPI0S31 | I/O | TTL | EPI module 0 signal 31. |
| | I2C3SDA | I/O | OD | I ² C module 3 data. |
| | M0PWM7 | O | TTL | Motion Control Module 0 PWM 7. This signal is controlled by Module 0 PWM Generator 3. |
| V18 | NC | - | - | No connect. Leave the pin electrically unconnected/isolated. |
| V19 | NC | - | - | No connect. Leave the pin electrically unconnected/isolated. |
| W1 | GND | - | Power | Ground reference for logic and I/O pins. |
| W2 | GND | - | Power | Ground reference for logic and I/O pins. |

Table 31-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type | Description |
|------------|-----------|----------|-------------|--|
| W3 | PA1 | I/O | TTL | GPIO port A bit 1. |
| | CAN0Tx | O | TTL | CAN module 0 transmit. |
| | I2C9SDA | I/O | OD | I ² C module 9 data. |
| | T0CCP1 | I/O | TTL | 16/32-Bit Timer 0 Capture/Compare/PWM 1. |
| | U0Tx | O | TTL | UART module 0 transmit. |
| W4 | PA5 | I/O | TTL | GPIO port A bit 5. |
| | I2C7SDA | I/O | OD | I ² C module 7 data. |
| | SSI0XDAT1 | I/O | TTL | SSI Module 0 Bi-directional Data Pin 1 (SSI0RX in Legacy SSI Mode). |
| | T2CCP1 | I/O | TTL | 16/32-Bit Timer 2 Capture/Compare/PWM 1. |
| | U3Tx | O | TTL | UART module 3 transmit. |
| W6 | PF2 | I/O | TTL | GPIO port F bit 2. |
| | EN0MDC | O | TTL | Ethernet 0 Management Data Clock. |
| | M0PWM2 | O | TTL | Motion Control Module 0 PWM 2. This signal is controlled by Module 0 PWM Generator 1. |
| | SSI3Fss | I/O | TTL | SSI module 3 frame signal. |
| | TRD0 | O | TTL | Trace data 0. |
| W7 | PF5 | I/O | TTL | GPIO port F bit 5. |
| | SSI3XDAT3 | I/O | TTL | SSI Module 3 Bi-directional Data Pin 3. |
| W9 | PR6 | I/O | TTL | GPIO port R bit 6. |
| | I2C4SCL | I/O | OD | I ² C module 4 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| | LCDDATA04 | I/O | TTL | LCD Data Pin 4 input/output. |
| | M0PWM6 | O | TTL | Motion Control Module 0 PWM 6. This signal is controlled by Module 0 PWM Generator 3. |
| | T1CCP0 | I/O | TTL | 16/32-Bit Timer 1 Capture/Compare/PWM 0. |
| | U1Tx | O | TTL | UART module 1 transmit. |
| W10 | PT0 | I/O | TTL | GPIO port T bit 0. |
| | CAN0Rx | I | TTL | CAN module 0 receive. |
| | EN0RXD0 | I | TTL | Ethernet 0 Receive Data 0. |
| | LCDDATA10 | I/O | TTL | LCD Data Pin 10 input/output. |
| | T6CCP0 | I/O | TTL | 16/32-Bit Timer 6 Capture/Compare/PWM 0. |
| W12 | PQ5 | I/O | TTL | GPIO port Q bit 5. |
| | EN0RXD0 | I | TTL | Ethernet 0 Receive Data 0. |
| | U1Tx | O | TTL | UART module 1 transmit. |
| W13 | EN0RXIP | I/O | TTL | Ethernet PHY positive receive differential input. |
| W15 | RBIAS | O | Analog | 4.87-kΩ resistor (1% precision) for Ethernet PHY. |

Table 31-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type | Description |
|------------|----------|----------|-------------|---|
| W16 | PK7 | I/O | TTL | GPIO port K bit 7. |
| | EN0TXD3 | O | TTL | Ethernet 0 Transmit Data 3. |
| | EPI0S24 | I/O | TTL | EPI module 0 signal 24. |
| | I2C4SDA | I/O | OD | I ² C module 4 data. |
| | MOFAULT2 | I | TTL | Motion Control Module 0 PWM Fault 2. |
| | RTCCLK | O | TTL | Buffered version of the Hibernation module's 32.768-kHz clock. This signal is not output when the part is in Hibernate mode and before being configured after power-on reset. |
| | U0RI | I | TTL | UART module 0 Ring Indicator modem status input signal. |
| W18 | NC | - | - | No connect. Leave the pin electrically unconnected/isolated. |
| W19 | NC | - | - | No connect. Leave the pin electrically unconnected/isolated. |

31.2 Signals by Signal Name

Table 31-3. Signals by Signal Name

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description |
|----------|------------|--------------------------|----------|-------------|---------------------------------------|
| AIN0 | G2 | PE3 | I | Analog | Analog-to-digital converter input 0. |
| AIN1 | G1 | PE2 | I | Analog | Analog-to-digital converter input 1. |
| AIN2 | H2 | PE1 | I | Analog | Analog-to-digital converter input 2. |
| AIN3 | H3 | PE0 | I | Analog | Analog-to-digital converter input 3. |
| AIN4 | B2 | PD7 | I | Analog | Analog-to-digital converter input 4. |
| AIN5 | B3 | PD6 | I | Analog | Analog-to-digital converter input 5. |
| AIN6 | B4 | PD5 | I | Analog | Analog-to-digital converter input 6. |
| AIN7 | A4 | PD4 | I | Analog | Analog-to-digital converter input 7. |
| AIN8 | B5 | PE5 | I | Analog | Analog-to-digital converter input 8. |
| AIN9 | A5 | PE4 | I | Analog | Analog-to-digital converter input 9. |
| AIN10 | C6 | PB4 | I | Analog | Analog-to-digital converter input 10. |
| AIN11 | B6 | PB5 | I | Analog | Analog-to-digital converter input 11. |
| AIN12 | D1 | PD3 | I | Analog | Analog-to-digital converter input 12. |
| AIN13 | D2 | PD2 | I | Analog | Analog-to-digital converter input 13. |
| AIN14 | C1 | PD1 | I | Analog | Analog-to-digital converter input 14. |
| AIN15 | C2 | PD0 | I | Analog | Analog-to-digital converter input 15. |
| AIN16 | J1 | PK0 | I | Analog | Analog-to-digital converter input 16. |
| AIN17 | J2 | PK1 | I | Analog | Analog-to-digital converter input 17. |
| AIN18 | K1 | PK2 | I | Analog | Analog-to-digital converter input 18. |
| AIN19 | K2 | PK3 | I | Analog | Analog-to-digital converter input 19. |
| AIN20 | A7 | PE6 | I | Analog | Analog-to-digital converter input 20. |
| AIN21 | B7 | PE7 | I | Analog | Analog-to-digital converter input 21. |
| AIN22 | A8 | PP7 | I | Analog | Analog-to-digital converter input 22. |
| AIN23 | B8 | PP6 | I | Analog | Analog-to-digital converter input 23. |
| C0+ | L2 | PC6 | I | Analog | Analog comparator 0 positive input. |

Table 31-3. Signals by Signal Name (continued)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description |
|-------------|-----------------|-------------------------------|----------|-------------|---|
| C0- | K3 | PC7 | I | Analog | Analog comparator 0 negative input. |
| C0o | C2 G18 | PD0 (5) PL2 (5) | O | TTL | Analog comparator 0 output. |
| C1+ | M1 | PC5 | I | Analog | Analog comparator 1 positive input. |
| C1- | M2 | PC4 | I | Analog | Analog comparator 1 negative input. |
| C1o | C1 J18 | PD1 (5) PL3 (5) | O | TTL | Analog comparator 1 output. |
| C2+ | D6 | PP0 | I | Analog | Analog comparator 2 positive input. |
| C2- | D7 | PP1 | I | Analog | Analog comparator 2 negative input. |
| C2o | D2 | PD2 (5) | O | TTL | Analog comparator 2 output. |
| CAN0Rx | V3 W10 | PA0 (7) PT0 (7) | I | TTL | CAN module 0 receive. |
| CAN0Tx | W3 V10 | PA1 (7) PT1 (7) | O | TTL | CAN module 0 transmit. |
| CAN1Rx | A16 E18 | PB0 (7) PT2 (7) | I | TTL | CAN module 1 receive. |
| CAN1Tx | B16 F17 | PB1 (7) PT3 (7) | O | TTL | CAN module 1 transmit. |
| DIVSCLK | A13 | PQ4 (7) | O | TTL | An optionally divided reference clock output based on a selected clock source. Note that this signal is not synchronized to the System Clock. |
| EN0COL | N18 | PM7 (14) | I | TTL | Ethernet 0 Collision Detect. |
| EN0CRS | N19 | PM6 (14) | I | TTL | Ethernet 0 Carrier Sense. |
| EN0INTRN | U19 D6 | PK4 (7) PP0 (7) | I | TTL | Ethernet 0 Interrupt from the Ethernet PHY. |
| EN0LED0 | U6 U19 | PF0 (5) PK4 (5) | O | TTL | Ethernet 0 LED 0. |
| EN0LED1 | V7 V16 | PF4 (5) PK6 (5) | O | TTL | Ethernet 0 LED 1. |
| EN0LED2 | V6 V17 | PF1 (5) PK5 (5) | O | TTL | Ethernet 0 LED 2. |
| EN0MDC | A17 W6 | PB2 (5) PF2 (5) | O | TTL | Ethernet 0 Management Data Clock. |
| EN0MDIO | B17 T7 | PB3 (5) PF3 (5) | I/O | TTL | Ethernet 0 Management Data Input/Output signal. |
| EN0PPS | N15 T2 C8 | PG0 (5) PH5 (5) PJ0 (5) | O | TTL | Ethernet 0 Pulse-Per-Second (PPS) Output. |
| EN0RREF_CLK | M18 | PM4 (14) | I/O | TTL | Ethernet 0 Reference Clock. |
| EN0RXCK | V5 | PA6 (14) | I | TTL | Ethernet 0 Receive Clock. |
| EN0RXD0 | W12 W10 | PQ5 (14) PT0 (14) | I | TTL | Ethernet 0 Receive Data 0. |
| EN0RXD1 | U15 V10 | PQ6 (14) PT1 (14) | I | TTL | Ethernet 0 Receive Data 1. |
| EN0RXD2 | V17 | PK5 (14) | I | TTL | Ethernet 0 Receive Data 2. |
| EN0RXD3 | U19 | PK4 (14) | I | TTL | Ethernet 0 Receive Data 3. |

Table 31-3. Signals by Signal Name (continued)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description |
|----------|------------|--------------------------|----------|-------------|---|
| EN0RXDV | U14 R13 | PG7 (14) PS7 (14) | I | TTL | Ethernet 0 Receive Data Valid. |
| EN0RXER | V12 U10 | PG6 (14) PS6 (14) | I | TTL | Ethernet 0 Receive Error. |
| EN0RXIN | V13 | fixed | I/O | TTL | Ethernet PHY negative receive differential input. |
| EN0RXIP | W13 | fixed | I/O | TTL | Ethernet PHY positive receive differential input. |
| EN0TXCK | V11 | PG2 (14) | I | TTL | Ethernet 0 Transmit Clock. |
| EN0TXD0 | K17 V9 | PG4 (14) PS4 (14) | O | TTL | Ethernet 0 Transmit Data 0. |
| EN0TXD1 | K15 T13 | PG5 (14) PS5 (14) | O | TTL | Ethernet 0 Transmit Data 1. |
| EN0TXD2 | V16 | PK6 (14) | O | TTL | Ethernet 0 Transmit Data 2. |
| EN0TXD3 | W16 | PK7 (14) | O | TTL | Ethernet 0 Transmit Data 3. |
| EN0TXEN | M16 R10 | PG3 (14) PR7 (14) | O | TTL | Ethernet 0 Transmit Enable. |
| EN0TXER | T12 | PN6 (14) | O | TTL | Ethernet 0 transmit error. |
| EN0TXON | V14 | fixed | I/O | TTL | Ethernet PHY negative transmit differential output. |
| EN0TXOP | V15 | fixed | I/O | TTL | Ethernet PHY positive transmit differential output. |
| EPI0S0 | P4 J1 | PH0 (15) PK0 (15) | I/O | TTL | EPI module 0 signal 0. |
| EPI0S1 | R2 J2 | PH1 (15) PK1 (15) | I/O | TTL | EPI module 0 signal 1. |
| EPI0S2 | R1 K1 | PH2 (15) PK2 (15) | I/O | TTL | EPI module 0 signal 2. |
| EPI0S3 | T1 K2 | PH3 (15) PK3 (15) | I/O | TTL | EPI module 0 signal 3. |
| EPI0S4 | K3 | PC7 (15) | I/O | TTL | EPI module 0 signal 4. |
| EPI0S5 | L2 | PC6 (15) | I/O | TTL | EPI module 0 signal 5. |
| EPI0S6 | M1 | PC5 (15) | I/O | TTL | EPI module 0 signal 6. |
| EPI0S7 | M2 | PC4 (15) | I/O | TTL | EPI module 0 signal 7. |
| EPI0S8 | V5 | PA6 (15) | I/O | TTL | EPI module 0 signal 8. |
| EPI0S9 | R7 | PA7 (15) | I/O | TTL | EPI module 0 signal 9. |
| EPI0S10 | T14 | PG1 (15) | I/O | TTL | EPI module 0 signal 10. |
| EPI0S11 | N15 | PG0 (15) | I/O | TTL | EPI module 0 signal 11. |
| EPI0S12 | L19 | PM3 (15) | I/O | TTL | EPI module 0 signal 12. |
| EPI0S13 | L18 | PM2 (15) | I/O | TTL | EPI module 0 signal 13. |
| EPI0S14 | K19 | PM1 (15) | I/O | TTL | EPI module 0 signal 14. |
| EPI0S15 | K18 | PM0 (15) | I/O | TTL | EPI module 0 signal 15. |
| EPI0S16 | G16 | PL0 (15) | I/O | TTL | EPI module 0 signal 16. |
| EPI0S17 | H19 | PL1 (15) | I/O | TTL | EPI module 0 signal 17. |
| EPI0S18 | G18 | PL2 (15) | I/O | TTL | EPI module 0 signal 18. |
| EPI0S19 | J18 | PL3 (15) | I/O | TTL | EPI module 0 signal 19. |
| EPI0S20 | E3 | PQ0 (15) | I/O | TTL | EPI module 0 signal 20. |

Table 31-3. Signals by Signal Name (continued)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description |
|----------|--|--------------------------|----------|-------------|---|
| EPI0S21 | E2 | PQ1 (15) | I/O | TTL | EPI module 0 signal 21. |
| EPI0S22 | H4 | PQ2 (15) | I/O | TTL | EPI module 0 signal 22. |
| EPI0S23 | M4 | PQ3 (15) | I/O | TTL | EPI module 0 signal 23. |
| EPI0S24 | W16 | PK7 (15) | I/O | TTL | EPI module 0 signal 24. |
| EPI0S25 | V16 | PK6 (15) | I/O | TTL | EPI module 0 signal 25. |
| EPI0S26 | H18 | PL4 (15) | I/O | TTL | EPI module 0 signal 26. |
| EPI0S27 | A17 | PB2 (15) | I/O | TTL | EPI module 0 signal 27. |
| EPI0S28 | B17 | PB3 (15) | I/O | TTL | EPI module 0 signal 28. |
| EPI0S29 | A11 B13 | PN2 (15) PP2 (15) | I/O | TTL | EPI module 0 signal 29. |
| EPI0S30 | B10 C12 | PN3 (15) PP3 (15) | I/O | TTL | EPI module 0 signal 30. |
| EPI0S31 | V17 | PK5 (15) | I/O | TTL | EPI module 0 signal 31. |
| EPI0S32 | U19 | PK4 (15) | I/O | TTL | EPI module 0 signal 32. |
| EPI0S33 | G19 | PL5 (15) | I/O | TTL | EPI module 0 signal 33. |
| EPI0S34 | A10 | PN4 (15) | I/O | TTL | EPI module 0 signal 34. |
| EPI0S35 | B9 | PN5 (15) | I/O | TTL | EPI module 0 signal 35. |
| GND | F10 H10 H11 H12 J11 J12 K6 K9 P16 K10 R17 K13 K14 L8 L9 M8 M9 M10 N10 A1 A2 B1 V1 W1 W2 A18 A19 B19 | fixed | - | Power | Ground reference for logic and I/O pins. |
| GNDA | G4 | fixed | - | Power | The ground reference for the analog circuits (ADC, Analog Comparators, etc.). These are separated from GND to minimize the electrical noise contained on VDD from affecting the analog functions. |

Table 31-3. Signals by Signal Name (continued)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description |
|-------------------------|-------------------------------|---|----------|-------------|--|
| GNDX | R18 | fixed | - | Power | GND for the Hibernation oscillator. When using a crystal clock source, this pin should be connected to digital ground along with the crystal load capacitors. When using an external oscillator, this pin should be connected to digital ground. |
| GNDX2 | D18 | fixed | - | Power | GND for the MOSC. When using a crystal clock source, this pin should be connected to digital ground along with the crystal load capacitors. When using an external oscillator, this pin should be connected to digital ground. |
| $\overline{\text{HTB}}$ | M17 | fixed | O | TTL | An output that indicates the processor is in Hibernation mode. |
| I2C0SCL | A17 | PB2 (2) | I/O | OD | I ² C module 0 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| I2C0SDA | B17 | PB3 (2) | I/O | OD | I ² C module 0 data. |
| I2C1SCL | N15 N5 | PG0 (2) PR0 (2) | I/O | OD | I ² C module 1 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| I2C1SDA | T14 N4 | PG1 (2) PR1 (2) | I/O | OD | I ² C module 1 data. |
| I2C2SCL | V11 H19 B9 B12 N2 | PG2 (2) PL1 (2) PN5 (3) PP5 (2) PR2 (2) | I/O | OD | I ² C module 2 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| I2C2SDA | M16 G16 A10 B8 V8 | PG3 (2) PL0 (2) PN4 (3) PP6 (2) PR3 (2) | I/O | OD | I ² C module 2 data. |
| I2C3SCL | K17 U19 P3 | PG4 (2) PK4 (2) PR4 (2) | I/O | OD | I ² C module 3 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| I2C3SDA | K15 V17 P2 | PG5 (2) PK5 (2) PR5 (2) | I/O | OD | I ² C module 3 data. |
| I2C4SCL | V12 V16 W9 | PG6 (2) PK6 (2) PR6 (2) | I/O | OD | I ² C module 4 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| I2C4SDA | U14 W16 R10 | PG7 (2) PK7 (2) PR7 (2) | I/O | OD | I ² C module 4 data. |
| I2C5SCL | A16 C6 | PB0 (2) PB4 (2) | I/O | OD | I ² C module 5 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |

Table 31-3. Signals by Signal Name (continued)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description |
|-----------|------------|--------------------------|----------|-------------|--|
| I2C6SDA | R7 F1 | PA7 (2) PB7 (2) | I/O | OD | I ² C module 6 data. |
| I2C7SCL | V4 C2 | PA4 (2) PD0 (2) | I/O | OD | I ² C module 7 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| I2C7SDA | W4 C1 | PA5 (2) PD1 (2) | I/O | OD | I ² C module 7 data. |
| I2C8SCL | T6 D2 | PA2 (2) PD2 (2) | I/O | OD | I ² C module 8 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| I2C8SDA | U5 D1 | PA3 (2) PD3 (2) | I/O | OD | I ² C module 8 data. |
| I2C9SCL | V3 A7 | PA0 (2) PE6 (2) | I/O | OD | I ² C module 9 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| I2C9SDA | W3 B7 | PA1 (2) PE7 (2) | I/O | OD | I ² C module 9 data. |
| IDX0 | J18 U10 | PL3 (6) PS6 (6) | I | TTL | QE1 module 0 index. |
| LCDAC | N1 | PJ6 (15) | O | TTL | LCD AC bias or latch enable in Raster mode; Primary chip select (CS0)/Primary Enable (E0) in LIDD MPU/Hitachi mode |
| LCDCP | N5 | PR0 (15) | O | TTL | LCD Pixel Clock in Raster mode; read strobe or read/write strobe in LIDD mode |
| LCDDATA00 | P3 | PR4 (15) | I/O | TTL | LCD Data Pin 0 input/output. |
| LCDDATA01 | P2 | PR5 (15) | I/O | TTL | LCD Data Pin 1 input/output. |
| LCDDATA02 | U8 | PF7 (15) | I/O | TTL | LCD Data Pin 2 input/output. |
| LCDDATA03 | V8 | PR3 (15) | I/O | TTL | LCD Data Pin 3 input/output. |
| LCDDATA04 | W9 | PR6 (15) | I/O | TTL | LCD Data Pin 4 input/output. |
| LCDDATA05 | R10 | PR7 (15) | I/O | TTL | LCD Data Pin 5 input/output. |
| LCDDATA06 | V9 | PS4 (15) | I/O | TTL | LCD Data Pin 6 input/output. |
| LCDDATA07 | T13 | PS5 (15) | I/O | TTL | LCD Data Pin 7 input/output. |
| LCDDATA08 | U10 | PS6 (15) | I/O | TTL | LCD Data Pin 8 input/output. |
| LCDDATA09 | R13 | PS7 (15) | I/O | TTL | LCD Data Pin 9 input/output. |
| LCDDATA10 | W10 | PT0 (15) | I/O | TTL | LCD Data Pin 10 input/output. |
| LCDDATA11 | V10 | PT1 (15) | I/O | TTL | LCD Data Pin 11 input/output. |
| LCDDATA12 | U12 | PN7 (15) | I/O | TTL | LCD Data Pin 12 input/output. |
| LCDDATA13 | T12 | PN6 (15) | I/O | TTL | LCD Data Pin 13 input/output. |
| LCDDATA14 | H17 | PJ2 (15) | I/O | TTL | LCD Data Pin 14 input/output. |
| LCDDATA15 | F16 | PJ3 (15) | I/O | TTL | LCD Data Pin 15 input/output. |
| LCDDATA16 | F18 | PJ4 (15) | O | TTL | LCD Data Pin 16 output. |
| LCDDATA17 | E17 | PJ5 (15) | O | TTL | LCD Data Pin 17 output. |
| LCDDATA18 | E18 | PT2 (15) | O | TTL | LCD Data Pin 18 output. |
| LCDDATA19 | F17 | PT3 (15) | O | TTL | LCD Data Pin 19 output. |
| LCDDATA20 | D12 | PS0 (15) | O | TTL | LCD Data Pin 20 output. |

Table 31-3. Signals by Signal Name (continued)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description |
|-----------|---------------------------------------|--------------------------|----------|-------------|---|
| LCDDATA21 | D13 | PS1 (15) | O | TTL | LCD Data Pin 21 output. |
| LCDDATA22 | B14 | PS2 (15) | O | TTL | LCD Data Pin 22 output. |
| LCDDATA23 | A14 | PS3 (15) | O | TTL | LCD Data Pin 23 output. |
| LCDFP | N4 | PR1 (15) | O | TTL | LCD Frame Clock or VSYNC in Raster mode; Address Latch Enable in LIDD mode |
| LCDLP | N2 | PR2 (15) | O | TTL | LCD Line Clock or HSYNC in Raster mode; Write Strobe or Direction bit in LIDD mode |
| LCDMCLK | T8 | PF6 (15) | O | TTL | LCD Memory Clock/Secondary chip Select (CS1)/Secondary Enable (E1) in LIDD Synchronous/Async MPU/Hitachi mode |
| MOFAULT0 | V7 D12 | PF4 (6) PS0 (6) | I | TTL | Motion Control Module 0 PWM Fault 0. |
| MOFAULT1 | V16 D13 | PK6 (6) PS1 (6) | I | TTL | Motion Control Module 0 PWM Fault 1. |
| MOFAULT2 | W16 B14 | PK7 (6) PS2 (6) | I | TTL | Motion Control Module 0 PWM Fault 2. |
| MOFAULT3 | G16 A14 | PL0 (6) PS3 (6) | I | TTL | Motion Control Module 0 PWM Fault 3. |
| MOPWM0 | U6 N5 | PF0 (6) PR0 (6) | O | TTL | Motion Control Module 0 PWM 0. This signal is controlled by Module 0 PWM Generator 0. |
| MOPWM1 | V6 N4 | PF1 (6) PR1 (6) | O | TTL | Motion Control Module 0 PWM 1. This signal is controlled by Module 0 PWM Generator 0. |
| MOPWM2 | W6 N2 | PF2 (6) PR2 (6) | O | TTL | Motion Control Module 0 PWM 2. This signal is controlled by Module 0 PWM Generator 1. |
| MOPWM3 | T7 V8 | PF3 (6) PR3 (6) | O | TTL | Motion Control Module 0 PWM 3. This signal is controlled by Module 0 PWM Generator 1. |
| MOPWM4 | N15 P3 | PG0 (6) PR4 (6) | O | TTL | Motion Control Module 0 PWM 4. This signal is controlled by Module 0 PWM Generator 2. |
| MOPWM5 | T14 P2 | PG1 (6) PR5 (6) | O | TTL | Motion Control Module 0 PWM 5. This signal is controlled by Module 0 PWM Generator 2. |
| MOPWM6 | U19 W9 | PK4 (6) PR6 (6) | O | TTL | Motion Control Module 0 PWM 6. This signal is controlled by Module 0 PWM Generator 3. |
| MOPWM7 | V17 R10 | PK5 (6) PR7 (6) | O | TTL | Motion Control Module 0 PWM 7. This signal is controlled by Module 0 PWM Generator 3. |
| NC | C5 V18 V19 W18 W19 E13 | fixed | - | - | No connect. Leave the pin electrically unconnected/isolated. |
| NMI | B2 B7 | PD7 (8) PE7 (8) | I | TTL | Non-maskable interrupt. |
| OSC0 | E19 | fixed | I | Analog | Main oscillator crystal input or an external clock reference input. |
| OSC1 | D19 | fixed | O | Analog | Main oscillator crystal output. Leave unconnected when using a single-ended clock source. |
| OWALT | K15 B12 | PG5 (5) PP5 (4) | I/O | TTL | 1-Wire Optional 2nd signal to be used as output. |

Table 31-3. Signals by Signal Name (continued)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description |
|----------|-------------------------------------|--|----------|-------------|---|
| OWIRE | G2 K17 V12 U14 D8 A8 | PE3 (5) PG4 (5) PG6 (5) PG7 (5) PP4 (4) PP7 (5) | I/O | TTL | 1-Wire Single Bus Pin. This signal is input only if 1-Wire Alternate Output is enabled. |
| PA0 | V3 | - | I/O | TTL | GPIO port A bit 0. |
| PA1 | W3 | - | I/O | TTL | GPIO port A bit 1. |
| PA2 | T6 | - | I/O | TTL | GPIO port A bit 2. |
| PA3 | U5 | - | I/O | TTL | GPIO port A bit 3. |
| PA4 | V4 | - | I/O | TTL | GPIO port A bit 4. |
| PA5 | W4 | - | I/O | TTL | GPIO port A bit 5. |
| PA6 | V5 | - | I/O | TTL | GPIO port A bit 6. |
| PA7 | R7 | - | I/O | TTL | GPIO port A bit 7. |
| PB0 | A16 | - | I/O | TTL | GPIO port B bit 0. |
| PB1 | B16 | - | I/O | TTL | GPIO port B bit 1. |
| PB2 | A17 | - | I/O | TTL | GPIO port B bit 2. |
| PB3 | B17 | - | I/O | TTL | GPIO port B bit 3. |
| PB4 | C6 | - | I/O | TTL | GPIO port B bit 4. |
| PB5 | B6 | - | I/O | TTL | GPIO port B bit 5. |
| PB6 | F2 | - | I/O | TTL | GPIO port B bit 6. |
| PB7 | F1 | - | I/O | TTL | GPIO port B bit 7. |
| PC0 | B15 | - | I/O | TTL | GPIO port C bit 0. |
| PC1 | C15 | - | I/O | TTL | GPIO port C bit 1. |
| PC2 | D14 | - | I/O | TTL | GPIO port C bit 2. |
| PC3 | C14 | - | I/O | TTL | GPIO port C bit 3. |
| PC4 | M2 | - | I/O | TTL | GPIO port C bit 4. |
| PC5 | M1 | - | I/O | TTL | GPIO port C bit 5. |
| PC6 | L2 | - | I/O | TTL | GPIO port C bit 6. |
| PC7 | K3 | - | I/O | TTL | GPIO port C bit 7. |
| PD0 | C2 | - | I/O | TTL | GPIO port D bit 0. |
| PD1 | C1 | - | I/O | TTL | GPIO port D bit 1. |
| PD2 | D2 | - | I/O | TTL | GPIO port D bit 2. |
| PD3 | D1 | - | I/O | TTL | GPIO port D bit 3. |
| PD4 | A4 | - | I/O | TTL | GPIO port D bit 4. |
| PD5 | B4 | - | I/O | TTL | GPIO port D bit 5. |
| PD6 | B3 | - | I/O | TTL | GPIO port D bit 6. |
| PD7 | B2 | - | I/O | TTL | GPIO port D bit 7. |
| PE0 | H3 | - | I/O | TTL | GPIO port E bit 0. |
| PE1 | H2 | - | I/O | TTL | GPIO port E bit 1. |
| PE2 | G1 | - | I/O | TTL | GPIO port E bit 2. |
| PE3 | G2 | - | I/O | TTL | GPIO port E bit 3. |

Table 31-3. Signals by Signal Name (continued)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description |
|----------|------------|--------------------------|----------|-------------|-----------------------|
| PE4 | A5 | - | I/O | TTL | GPIO port E bit 4. |
| PE5 | B5 | - | I/O | TTL | GPIO port E bit 5. |
| PE6 | A7 | - | I/O | TTL | GPIO port E bit 6. |
| PE7 | B7 | - | I/O | TTL | GPIO port E bit 7. |
| PF0 | U6 | - | I/O | TTL | GPIO port F bit 0. |
| PF1 | V6 | - | I/O | TTL | GPIO port F bit 1. |
| PF2 | W6 | - | I/O | TTL | GPIO port F bit 2. |
| PF3 | T7 | - | I/O | TTL | GPIO port F bit 3. |
| PF4 | V7 | - | I/O | TTL | GPIO port F bit 4. |
| PF5 | W7 | - | I/O | TTL | GPIO port F bit 5. |
| PF6 | T8 | - | I/O | TTL | GPIO port F bit 6. |
| PF7 | U8 | - | I/O | TTL | GPIO port F bit 7. |
| PG0 | N15 | - | I/O | TTL | GPIO port G bit 0. |
| PG1 | T14 | - | I/O | TTL | GPIO port G bit 1. |
| PG2 | V11 | - | I/O | TTL | GPIO port G bit 2. |
| PG3 | M16 | - | I/O | TTL | GPIO port G bit 3. |
| PG4 | K17 | - | I/O | TTL | GPIO port G bit 4. |
| PG5 | K15 | - | I/O | TTL | GPIO port G bit 5. |
| PG6 | V12 | - | I/O | TTL | GPIO port G bit 6. |
| PG7 | U14 | - | I/O | TTL | GPIO port G bit 7. |
| PH0 | P4 | - | I/O | TTL | GPIO port H bit 0. |
| PH1 | R2 | - | I/O | TTL | GPIO port H bit 1. |
| PH2 | R1 | - | I/O | TTL | GPIO port H bit 2. |
| PH3 | T1 | - | I/O | TTL | GPIO port H bit 3. |
| PH4 | R3 | - | I/O | TTL | GPIO port H bit 4. |
| PH5 | T2 | - | I/O | TTL | GPIO port H bit 5. |
| PH6 | U2 | - | I/O | TTL | GPIO port H bit 6. |
| PH7 | V2 | - | I/O | TTL | GPIO port H bit 7. |
| PhA0 | H19 V9 | PL1 (6) PS4 (6) | I | TTL | QEI module 0 phase A. |
| PhB0 | G18 T13 | PL2 (6) PS5 (6) | I | TTL | QEI module 0 phase B. |
| PJ0 | C8 | - | I/O | TTL | GPIO port J bit 0. |
| PJ1 | E7 | - | I/O | TTL | GPIO port J bit 1. |
| PJ2 | H17 | - | I/O | TTL | GPIO port J bit 2. |
| PJ3 | F16 | - | I/O | TTL | GPIO port J bit 3. |
| PJ4 | F18 | - | I/O | TTL | GPIO port J bit 4. |
| PJ5 | E17 | - | I/O | TTL | GPIO port J bit 5. |
| PJ6 | N1 | - | I/O | TTL | GPIO port J bit 6. |
| PJ7 | K5 | - | I/O | TTL | GPIO port J bit 7. |
| PK0 | J1 | - | I/O | TTL | GPIO port K bit 0. |

Table 31-3. Signals by Signal Name (continued)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description |
|----------|------------|--------------------------|----------|-------------|--------------------|
| PK1 | J2 | - | I/O | TTL | GPIO port K bit 1. |
| PK2 | K1 | - | I/O | TTL | GPIO port K bit 2. |
| PK3 | K2 | - | I/O | TTL | GPIO port K bit 3. |
| PK4 | U19 | - | I/O | TTL | GPIO port K bit 4. |
| PK5 | V17 | - | I/O | TTL | GPIO port K bit 5. |
| PK6 | V16 | - | I/O | TTL | GPIO port K bit 6. |
| PK7 | W16 | - | I/O | TTL | GPIO port K bit 7. |
| PL0 | G16 | - | I/O | TTL | GPIO port L bit 0. |
| PL1 | H19 | - | I/O | TTL | GPIO port L bit 1. |
| PL2 | G18 | - | I/O | TTL | GPIO port L bit 2. |
| PL3 | J18 | - | I/O | TTL | GPIO port L bit 3. |
| PL4 | H18 | - | I/O | TTL | GPIO port L bit 4. |
| PL5 | G19 | - | I/O | TTL | GPIO port L bit 5. |
| PL6 | C18 | - | I/O | TTL | GPIO port L bit 6. |
| PL7 | B18 | - | I/O | TTL | GPIO port L bit 7. |
| PM0 | K18 | - | I/O | TTL | GPIO port M bit 0. |
| PM1 | K19 | - | I/O | TTL | GPIO port M bit 1. |
| PM2 | L18 | - | I/O | TTL | GPIO port M bit 2. |
| PM3 | L19 | - | I/O | TTL | GPIO port M bit 3. |
| PM4 | M18 | - | I/O | TTL | GPIO port M bit 4. |
| PM5 | G15 | - | I/O | TTL | GPIO port M bit 5. |
| PM6 | N19 | - | I/O | TTL | GPIO port M bit 6. |
| PM7 | N18 | - | I/O | TTL | GPIO port M bit 7. |
| PN0 | C10 | - | I/O | TTL | GPIO port N bit 0. |
| PN1 | B11 | - | I/O | TTL | GPIO port N bit 1. |
| PN2 | A11 | - | I/O | TTL | GPIO port N bit 2. |
| PN3 | B10 | - | I/O | TTL | GPIO port N bit 3. |
| PN4 | A10 | - | I/O | TTL | GPIO port N bit 4. |
| PN5 | B9 | - | I/O | TTL | GPIO port N bit 5. |
| PN6 | T12 | - | I/O | TTL | GPIO port N bit 6. |
| PN7 | U12 | - | I/O | TTL | GPIO port N bit 7. |
| PP0 | D6 | - | I/O | TTL | GPIO port P bit 0. |
| PP1 | D7 | - | I/O | TTL | GPIO port P bit 1. |
| PP2 | B13 | - | I/O | TTL | GPIO port P bit 2. |
| PP3 | C12 | - | I/O | TTL | GPIO port P bit 3. |
| PP4 | D8 | - | I/O | TTL | GPIO port P bit 4. |
| PP5 | B12 | - | I/O | TTL | GPIO port P bit 5. |
| PP6 | B8 | - | I/O | TTL | GPIO port P bit 6. |
| PP7 | A8 | - | I/O | TTL | GPIO port P bit 7. |
| PQ0 | E3 | - | I/O | TTL | GPIO port Q bit 0. |
| PQ1 | E2 | - | I/O | TTL | GPIO port Q bit 1. |

Table 31-3. Signals by Signal Name (continued)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description |
|-------------------------|------------------|-------------------------------|----------|-------------|---|
| PQ2 | H4 | - | I/O | TTL | GPIO port Q bit 2. |
| PQ3 | M4 | - | I/O | TTL | GPIO port Q bit 3. |
| PQ4 | A13 | - | I/O | TTL | GPIO port Q bit 4. |
| PQ5 | W12 | - | I/O | TTL | GPIO port Q bit 5. |
| PQ6 | U15 | - | I/O | TTL | GPIO port Q bit 6. |
| PQ7 | M3 | - | I/O | TTL | GPIO port Q bit 7. |
| PR0 | N5 | - | I/O | TTL | GPIO port R bit 0. |
| PR1 | N4 | - | I/O | TTL | GPIO port R bit 1. |
| PR2 | N2 | - | I/O | TTL | GPIO port R bit 2. |
| PR3 | V8 | - | I/O | TTL | GPIO port R bit 3. |
| PR4 | P3 | - | I/O | TTL | GPIO port R bit 4. |
| PR5 | P2 | - | I/O | TTL | GPIO port R bit 5. |
| PR6 | W9 | - | I/O | TTL | GPIO port R bit 6. |
| PR7 | R10 | - | I/O | TTL | GPIO port R bit 7. |
| PS0 | D12 | - | I/O | TTL | GPIO port S bit 0. |
| PS1 | D13 | - | I/O | TTL | GPIO port S bit 1. |
| PS2 | B14 | - | I/O | TTL | GPIO port S bit 2. |
| PS3 | A14 | - | I/O | TTL | GPIO port S bit 3. |
| PS4 | V9 | - | I/O | TTL | GPIO port S bit 4. |
| PS5 | T13 | - | I/O | TTL | GPIO port S bit 5. |
| PS6 | U10 | - | I/O | TTL | GPIO port S bit 6. |
| PS7 | R13 | - | I/O | TTL | GPIO port S bit 7. |
| PT0 | W10 | - | I/O | TTL | GPIO port T bit 0. |
| PT1 | V10 | - | I/O | TTL | GPIO port T bit 1. |
| PT2 | E18 | - | I/O | TTL | GPIO port T bit 2. |
| PT3 | F17 | - | I/O | TTL | GPIO port T bit 3. |
| RBIAS | W15 | fixed | O | Analog | 4.87-kΩ resistor (1% precision) for Ethernet PHY. |
| $\overline{\text{RST}}$ | P18 | fixed | I | TTL | System reset input. |
| RTCCLK | M1 W16 C12 | PC5 (7) PK7 (5) PP3 (7) | O | TTL | Buffered version of the Hibernation module's 32.768-kHz clock. This signal is not output when the part is in Hibernate mode and before being configured after power-on reset. |
| SSI0Clk | T6 | PA2 (15) | I/O | TTL | SSI module 0 clock |
| SSI0Fss | U5 | PA3 (15) | I/O | TTL | SSI module 0 frame signal |
| SSI0XDAT0 | V4 | PA4 (15) | I/O | TTL | SSI Module 0 Bi-directional Data Pin 0 (SSI0TX in Legacy SSI Mode). |
| SSI0XDAT1 | W4 | PA5 (15) | I/O | TTL | SSI Module 0 Bi-directional Data Pin 1 (SSI0RX in Legacy SSI Mode). |
| SSI0XDAT2 | V5 | PA6 (13) | I/O | TTL | SSI Module 0 Bi-directional Data Pin 2. |
| SSI0XDAT3 | R7 | PA7 (13) | I/O | TTL | SSI Module 0 Bi-directional Data Pin 3. |
| SSI1Clk | B6 | PB5 (15) | I/O | TTL | SSI module 1 clock. |
| SSI1Fss | C6 | PB4 (15) | I/O | TTL | SSI module 1 frame signal. |

Table 31-3. Signals by Signal Name (continued)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description |
|-----------|------------------------|--|----------|-------------|---|
| SSI1XDAT0 | A5 | PE4 (15) | I/O | TTL | SSI Module 1 Bi-directional Data Pin 0 (SSI1TX in Legacy SSI Mode). |
| SSI1XDAT1 | B5 | PE5 (15) | I/O | TTL | SSI Module 1 Bi-directional Data Pin 1 (SSI1RX in Legacy SSI Mode). |
| SSI1XDAT2 | A4 | PD4 (15) | I/O | TTL | SSI Module 1 Bi-directional Data Pin 2. |
| SSI1XDAT3 | B4 | PD5 (15) | I/O | TTL | SSI Module 1 Bi-directional Data Pin 3. |
| SSI2Clk | D1 U14 | PD3 (15) PG7 (15) | I/O | TTL | SSI module 2 clock. |
| SSI2Fss | D2 V12 | PD2 (15) PG6 (15) | I/O | TTL | SSI module 2 frame signal. |
| SSI2XDAT0 | C1 K15 | PD1 (15) PG5 (15) | I/O | TTL | SSI Module 2 Bi-directional Data Pin 0 (SSI2TX in Legacy SSI Mode). |
| SSI2XDAT1 | C2 K17 | PD0 (15) PG4 (15) | I/O | TTL | SSI Module 2 Bi-directional Data Pin 1 (SSI2RX in Legacy SSI Mode). |
| SSI2XDAT2 | B2 M16 | PD7 (15) PG3 (15) | I/O | TTL | SSI Module 2 Bi-directional Data Pin 2. |
| SSI2XDAT3 | B3 V11 | PD6 (15) PG2 (15) | I/O | TTL | SSI Module 2 Bi-directional Data Pin 3. |
| SSI3Clk | T7 E3 | PF3 (14) PQ0 (14) | I/O | TTL | SSI module 3 clock. |
| SSI3Fss | W6 E2 | PF2 (14) PQ1 (14) | I/O | TTL | SSI module 3 frame signal. |
| SSI3XDAT0 | V6 H4 | PF1 (14) PQ2 (14) | I/O | TTL | SSI Module 3 Bi-directional Data Pin 0 (SSI3TX in Legacy SSI Mode). |
| SSI3XDAT1 | U6 M4 | PF0 (14) PQ3 (14) | I/O | TTL | SSI Module 3 Bi-directional Data Pin 1 (SSI3RX in Legacy SSI Mode). |
| SSI3XDAT2 | V7 D6 | PF4 (14) PP0 (15) | I/O | TTL | SSI Module 3 Bi-directional Data Pin 2. |
| SSI3XDAT3 | W7 D7 | PF5 (14) PP1 (15) | I/O | TTL | SSI Module 3 Bi-directional Data Pin 3. |
| SWCLK | B15 | PC0 (1) | I | TTL | JTAG/SWD CLK. |
| SWDIO | C15 | PC1 (1) | I/O | TTL | JTAG TMS and SWDIO. |
| SWO | C14 | PC3 (1) | O | TTL | JTAG TDO and SWO. |
| T0CCP0 | V3 C2 H18 P3 | PA0 (3) PD0 (3) PL4 (3) PR4 (3) | I/O | TTL | 16/32-Bit Timer 0 Capture/Compare/PWM 0. |
| T0CCP1 | W3 C1 G19 P2 | PA1 (3) PD1 (3) PL5 (3) PR5 (3) | I/O | TTL | 16/32-Bit Timer 0 Capture/Compare/PWM 1. |
| T1CCP0 | T6 D2 C18 W9 | PA2 (3) PD2 (3) PL6 (3) PR6 (3) | I/O | TTL | 16/32-Bit Timer 1 Capture/Compare/PWM 0. |
| T1CCP1 | U5 D1 B18 R10 | PA3 (3) PD3 (3) PL7 (3) PR7 (3) | I/O | TTL | 16/32-Bit Timer 1 Capture/Compare/PWM 1. |

Table 31-3. Signals by Signal Name (continued)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description |
|----------|-------------------------|--|----------|-------------|--|

| U5Rx | L2 U2 | PC6 (1) PH6 (1) | I | TTL | UART module 5 receive. |
| U5Tx | K3 V2 | PC7 (1) PH7 (1) | O | TTL | UART module 5 transmit. |
| U6Rx | D6 | PP0 (1) | I | TTL | UART module 6 receive. |
| U6Tx | D7 | PP1 (1) | O | TTL | UART module 6 transmit. |
| U7Rx | M2 U2 | PC4 (1) PH6 (2) | I | TTL | UART module 7 receive. |
| U7Tx | M1 V2 | PC5 (1) PH7 (2) | O | TTL | UART module 7 transmit. |
| USB0CLK | B17 | PB3 (14) | O | TTL | 60-MHz clock to the external PHY. |
| USB0D0 | G16 | PL0 (14) | I/O | TTL | USB data 0. |
| USB0D1 | H19 | PL1 (14) | I/O | TTL | USB data 1. |
| USB0D2 | G18 | PL2 (14) | I/O | TTL | USB data 2. |
| USB0D3 | J18 | PL3 (14) | I/O | TTL | USB data 3. |
| USB0D4 | H18 | PL4 (14) | I/O | TTL | USB data 4. |

Table 31-3. Signals by Signal Name (continued)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description |
|----------|--|--------------------------------|----------|-------------|---|
| USB0D5 | G19 | PL5 (14) | I/O | TTL | USB data 5. |
| USB0D6 | B12 | PP5 (14) | I/O | TTL | USB data 6. |
| USB0D7 | D8 | PP4 (14) | I/O | TTL | USB data 7. |
| USB0DIR | C12 | PP3 (14) | O | TTL | Indicates that the external PHY is able to accept data from the USB controller. |
| USB0DM | B18 | PL7 | I/O | Analog | Bidirectional differential data pin (D- per USB specification) for USB0. |
| USB0DP | C18 | PL6 | I/O | Analog | Bidirectional differential data pin (D+ per USB specification) for USB0. |
| USB0EPEN | V5 R7 B3 | PA6 (5) PA7 (11) PD6 (5) | O | TTL | Optionally used in Host mode to control an external power source to supply power to the USB bus. |
| USB0ID | A16 | PB0 | I | Analog | This signal senses the state of the USB ID signal. The USB PHY enables an integrated pull-up, and an external element (USB connector) indicates the initial state of the USB controller (pulled down is the A side of the cable and pulled up is the B side). |
| USB0NXT | B13 | PP2 (14) | O | TTL | Asserted by the external PHY to throttle all data types. |
| USB0PFLT | R7 B2 | PA7 (5) PD7 (5) | I | TTL | Optionally used in Host mode by an external power source to indicate an error state by that power source. |
| USB0STP | A17 | PB2 (14) | O | TTL | Asserted by the USB controller to signal the end of a USB transmit packet or register write operation. |
| USB0VBUS | B16 | PB1 | I/O | Analog | This signal is used during the session request protocol. This signal allows the USB PHY to both sense the voltage level of VBUS, and pull up VBUS momentarily during VBUS pulsing. |
| VBAT | P19 | fixed | - | Power | Power source for the Hibernation module. It is normally connected to the positive terminal of a battery and serves as the battery backup/Hibernation module power-source supply. |
| VDD | G10 H9 J8 J9 J10 K7 K8 K11 N16 P17 K12 L10 L11 L12 M11 M12 P10 | fixed | - | Power | Positive supply for I/O and some logic. |

Table 31-3. Signals by Signal Name (continued)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description |
|----------|------------|--------------------------|----------|-------------|--|
| VDDA | F3 | fixed | - | Power | The positive supply for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions. VDDA pins must be supplied with a voltage that meets the specification in , regardless of system implementation. |
| VDDC | H16 E10 | fixed | - | Power | Positive supply for most of the logic function, including the processor core and most peripherals. The voltage on this pin is 1.2 V and is supplied by the on-chip LDO. The VDDC pins should only be connected to each other and an external capacitor as specified in Table 32-15 on page 2111 . |
| VREFA+ | F4 | fixed | - | Analog | A reference voltage used to specify the voltage at which the ADC converts to a maximum value. This pin is used in conjunction with VREFA-, which specifies the minimum value . The voltage that is applied to VREFA+ is the voltage with which an AINn signal is converted to 4095. The VREFA+ voltage is limited to the range specified in Table 32-44 on page 2138. |
| VREFA- | G5 | fixed | - | Analog | A reference voltage used to specify the input voltage at which the ADC converts to a minimum value. This pin is used in conjunction with VREFA+, which specifies the maximum value. In other words, the voltage that is applied to VREFA- is the voltage with which an AINn signal is converted to 0, while the voltage that is applied to VREFA+ is the voltage with which an AINn signal is converted to 4095. The VREFA- voltage is limited to the range specified in Table 32-44 on page 2138. |
| WAKE | U18 | fixed | I | TTL | An external input that brings the processor out of Hibernate mode when asserted. |
| XOSC0 | T18 | fixed | I | Analog | Hibernation module oscillator crystal input or an external clock reference input. Note that this is either a crystal or a 32.768-kHz oscillator for the Hibernation module RTC. |
| XOSC1 | T19 | fixed | O | Analog | Hibernation module oscillator crystal output. Leave unconnected when using a single-ended clock source. |

31.3 Signals by Function, Except for GPIO

Table 31-4. Signals by Function, Except for GPIO

| Function | Pin Name | Pin Number | Pin Type | Buffer Type | Description |
|----------|----------|-------------------------------------|----------|-------------|---|
| 1-Wire | OWALT | K15 B12 | I/O | TTL | 1-Wire Optional 2nd signal to be used as output. |
| | OWIRE | G2 K17 V12 U14 D8 A8 | I/O | TTL | 1-Wire Single Bus Pin. This signal is input only if 1-Wire Alternate Output is enabled. |

Table 31-4. Signals by Function, Except for GPIO (continued)

| Function | Pin Name | Pin Number | Pin Type | Buffer Type | Description |
|----------|----------|------------|----------|-------------|--|
| ADC | AIN0 | G2 | I | Analog | Analog-to-digital converter input 0. |
| | AIN1 | G1 | I | Analog | Analog-to-digital converter input 1. |
| | AIN2 | H2 | I | Analog | Analog-to-digital converter input 2. |
| | AIN3 | H3 | I | Analog | Analog-to-digital converter input 3. |
| | AIN4 | B2 | I | Analog | Analog-to-digital converter input 4. |
| | AIN5 | B3 | I | Analog | Analog-to-digital converter input 5. |
| | AIN6 | B4 | I | Analog | Analog-to-digital converter input 6. |
| | AIN7 | A4 | I | Analog | Analog-to-digital converter input 7. |
| | AIN8 | B5 | I | Analog | Analog-to-digital converter input 8. |
| | AIN9 | A5 | I | Analog | Analog-to-digital converter input 9. |
| | AIN10 | C6 | I | Analog | Analog-to-digital converter input 10. |
| | AIN11 | B6 | I | Analog | Analog-to-digital converter input 11. |
| | AIN12 | D1 | I | Analog | Analog-to-digital converter input 12. |
| | AIN13 | D2 | I | Analog | Analog-to-digital converter input 13. |
| | AIN14 | C1 | I | Analog | Analog-to-digital converter input 14. |
| | AIN15 | C2 | I | Analog | Analog-to-digital converter input 15. |
| | AIN16 | J1 | I | Analog | Analog-to-digital converter input 16. |
| | AIN17 | J2 | I | Analog | Analog-to-digital converter input 17. |
| | AIN18 | K1 | I | Analog | Analog-to-digital converter input 18. |
| | AIN19 | K2 | I | Analog | Analog-to-digital converter input 19. |
| | AIN20 | A7 | I | Analog | Analog-to-digital converter input 20. |
| | AIN21 | B7 | I | Analog | Analog-to-digital converter input 21. |
| | AIN22 | A8 | I | Analog | Analog-to-digital converter input 22. |
| | AIN23 | B8 | I | Analog | Analog-to-digital converter input 23. |
| VREFA+ | F4 | - | - | Analog | A reference voltage used to specify the voltage at which the ADC converts to a maximum value. This pin is used in conjunction with VREFA-, which specifies the minimum value. The voltage that is applied to VREFA+ is the voltage with which an AINn signal is converted to 4095. The VREFA+ voltage is limited to the range specified in Table 32-44 on page 2138. |
| VREFA- | G5 | - | - | Analog | A reference voltage used to specify the input voltage at which the ADC converts to a minimum value. This pin is used in conjunction with VREFA+, which specifies the maximum value. In other words, the voltage that is applied to VREFA- is the voltage with which an AINn signal is converted to 0, while the voltage that is applied to VREFA+ is the voltage with which an AINn signal is converted to 4095. The VREFA- voltage is limited to the range specified in Table 32-44 on page 2138. |

Table 31-4. Signals by Function, Except for GPIO (continued)

| Function | Pin Name | Pin Number | Pin Type | Buffer Type | Description |
|-------------------------|----------|------------|----------|-------------|-------------------------------------|
| Analog Comparators | C0+ | L2 | I | Analog | Analog comparator 0 positive input. |
| | C0- | K3 | I | Analog | Analog comparator 0 negative input. |
| | C0o | C2 G18 | O | TTL | Analog comparator 0 output. |
| | C1+ | M1 | I | Analog | Analog comparator 1 positive input. |
| | C1- | M2 | I | Analog | Analog comparator 1 negative input. |
| | C1o | C1 J18 | O | TTL | Analog comparator 1 output. |
| | C2+ | D6 | I | Analog | Analog comparator 2 positive input. |
| | C2- | D7 | I | Analog | Analog comparator 2 negative input. |
| | C2o | D2 | O | TTL | Analog comparator 2 output. |
| Controller Area Network | CAN0Rx | V3 W10 | I | TTL | CAN module 0 receive. |
| | CAN0Tx | W3 V10 | O | TTL | CAN module 0 transmit. |
| | CAN1Rx | A16 E18 | I | TTL | CAN module 1 receive. |
| | CAN1Tx | B16 F17 | O | TTL | CAN module 1 transmit. |
| Core | TRCLK | T7 | O | TTL | Trace clock. |
| | TRD0 | W6 | O | TTL | Trace data 0. |
| | TRD1 | V6 | O | TTL | Trace data 1. |
| | TRD2 | U6 | O | TTL | Trace data 2. |
| | TRD3 | V7 | O | TTL | Trace data 3. |

Table 31-4. Signals by Function, Except for GPIO (continued)

| Function | Pin Name | Pin Number | Pin Type | Buffer Type | Description |
|----------|------------|-----------------|----------|-------------|---|
| Ethernet | EN0COL | N18 | I | TTL | Ethernet 0 Collision Detect. |
| | EN0CRS | N19 | I | TTL | Ethernet 0 Carrier Sense. |
| | EN0INTRN | U19 D6 | I | TTL | Ethernet 0 Interrupt from the Ethernet PHY. |
| | EN0LED0 | U6 U19 | O | TTL | Ethernet 0 LED 0. |
| | EN0LED1 | V7 V16 | O | TTL | Ethernet 0 LED 1. |
| | EN0LED2 | V6 V17 | O | TTL | Ethernet 0 LED 2. |
| | EN0MDC | A17 W6 | O | TTL | Ethernet 0 Management Data Clock. |
| | EN0MDIO | B17 T7 | I/O | TTL | Ethernet 0 Management Data Input/Output signal. |
| | EN0PPS | N15 T2 C8 | O | TTL | Ethernet 0 Pulse-Per-Second (PPS) Output. |
| | EN0REF_CLK | M18 | I/O | TTL | Ethernet 0 Reference Clock. |
| | EN0RXCK | V5 | I | TTL | Ethernet 0 Receive Clock. |
| | EN0RXD0 | W12 W10 | I | TTL | Ethernet 0 Receive Data 0. |
| | EN0RXD1 | U15 V10 | I | TTL | Ethernet 0 Receive Data 1. |
| | EN0RXD2 | V17 | I | TTL | Ethernet 0 Receive Data 2. |
| | EN0RXD3 | U19 | I | TTL | Ethernet 0 Receive Data 3. |
| | EN0RXDV | U14 R13 | I | TTL | Ethernet 0 Receive Data Valid. |
| | EN0RXER | V12 U10 | I | TTL | Ethernet 0 Receive Error. |
| | EN0RXIN | V13 | I/O | TTL | Ethernet PHY negative receive differential input. |
| | EN0RXIP | W13 | I/O | TTL | Ethernet PHY positive receive differential input. |
| | EN0TXCK | V11 | I | TTL | Ethernet 0 Transmit Clock. |
| | EN0TXD0 | K17 V9 | O | TTL | Ethernet 0 Transmit Data 0. |
| | EN0TXD1 | K15 T13 | O | TTL | Ethernet 0 Transmit Data 1. |
| | EN0TXD2 | V16 | O | TTL | Ethernet 0 Transmit Data 2. |
| | EN0TXD3 | W16 | O | TTL | Ethernet 0 Transmit Data 3. |
| | EN0TXEN | M16 R10 | O | TTL | Ethernet 0 Transmit Enable. |
| | EN0TXER | T12 | O | TTL | Ethernet 0 transmit error. |
| | EN0TXON | V14 | I/O | TTL | Ethernet PHY negative transmit differential output. |
| | EN0TXOP | V15 | I/O | TTL | Ethernet PHY positive transmit differential output. |
| | RBIAS | W15 | O | Analog | 4.87-kΩ resistor (1% precision) for Ethernet PHY. |

Table 31-4. Signals by Function, Except for GPIO (continued)

| Function | Pin Name | Pin Number | Pin Type | Buffer Type | Description |

| | T6CCP1 | F1 D7 E2 V10 | I/O | TTL | 16/32-Bit Timer 6 Capture/Compare/PWM 1. |
| T7CCP0 | | | I/O | TTL | 16/32-Bit Timer 7 Capture/Compare/PWM 0. |

Table 31-4. Signals by Function, Except for GPIO (continued)

| Function | Pin Name | Pin Number | Pin Type | Buffer Type | Description |
|-----------|----------|------------------|----------|---|--|
| | | M2 H4 E18 | | | |
| | T7CCP1 | M1 M4 F17 | I/O | TTL | 16/32-Bit Timer 7 Capture/Compare/PWM 1. |
| Hibernate | GNDX | R18 | - | Power | GND for the Hibernation oscillator. When using a crystal clock source, this pin should be connected to digital ground along with the crystal load capacitors. When using an external oscillator, this pin should be connected to digital ground. |
| | HTB | M17 | O | TTL | An output that indicates the processor is in Hibernate mode. |
| | RTCCLK | M1 W16 C12 | O | TTL | Buffered version of the Hibernation module's 32.768-kHz clock. This signal is not output when the part is in Hibernate mode and before being configured after power-on reset. |
| | TMPR0 | N18 | I/O | TTL | Tamper signal 0. |
| | TMPR1 | N19 | I/O | TTL | Tamper signal 1. |
| | TMPR2 | G15 | I/O | TTL | Tamper signal 2. |
| | TMPR3 | M18 | I/O | TTL | Tamper signal 3. |
| | VBAT | P19 | - | Power | Power source for the Hibernation module. It is normally connected to the positive terminal of a battery and serves as the battery backup/Hibernation module power-source supply. |
| | WAKE | U18 | I | TTL | An external input that brings the processor out of Hibernate mode when asserted. |
| | XOSC0 | T18 | I | Analog | Hibernation module oscillator crystal input or an external clock reference input. Note that this is either a crystal or a 32.768-kHz oscillator for the Hibernation module RTC. |
| XOSC1 | T19 | O | Analog | Hibernation module oscillator crystal output. Leave unconnected when using a single-ended clock source. | |

Table 31-4. Signals by Function, Except for GPIO (continued)

| Function | Pin Name | Pin Number | Pin Type | Buffer Type | Description |
|----------|----------|-------------------------------|----------|-------------|--|
| I2C | I2C0SCL | A17 | I/O | OD | I ² C module 0 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| | I2C0SDA | B17 | I/O | OD | I ² C module 0 data. |
| | I2C1SCL | N15 N5 | I/O | OD | I ² C module 1 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| | I2C1SDA | T14 N4 | I/O | OD | I ² C module 1 data. |
| | I2C2SCL | V11 H19 B9 B12 N2 | I/O | OD | I ² C module 2 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| | I2C2SDA | M16 G16 A10 B8 V8 | I/O | OD | I ² C module 2 data. |
| | I2C3SCL | K17 U19 P3 | I/O | OD | I ² C module 3 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| | I2C3SDA | K15 V17 P2 | I/O | OD | I ² C module 3 data. |
| | I2C4SCL | V12 V16 W9 | I/O | OD | I ² C module 4 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| | I2C4SDA | U14 W16 R10 | I/O | OD | I ² C module 4 data. |
| | I2C5SCL | A16 C6 | I/O | OD | I ² C module 5 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| | I2C5SDA | B16 B6 | I/O | OD | I ² C module 5 data. |
| | I2C6SCL | V5 F2 | I/O | OD | I ² C module 6 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| | I2C6SDA | R7 F1 | I/O | OD | I ² C module 6 data. |
| | I2C7SCL | V4 C2 | I/O | OD | I ² C module 7 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| | I2C7SDA | W4 C1 | I/O | OD | I ² C module 7 data. |
| | I2C8SCL | T6 D2 | I/O | OD | I ² C module 8 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| | I2C8SDA | U5 D1 | I/O | OD | I ² C module 8 data. |

Table 31-4. Signals by Function, Except for GPIO (continued)

| Function | Pin Name | Pin Number | Pin Type | Buffer Type | Description |
|--------------|----------|------------|----------|-------------|--|
| | I2C9SCL | V3 A7 | I/O | OD | I ² C module 9 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| | I2C9SDA | W3 B7 | I/O | OD | I ² C module 9 data. |
| JTAG/SWD/SWO | SWCLK | B15 | I | TTL | JTAG/SWD CLK. |
| | SWDIO | C15 | I/O | TTL | JTAG TMS and SWDIO. |
| | SWO | C14 | O | TTL | JTAG TDO and SWO. |
| | TCK | B15 | I | TTL | JTAG/SWD CLK. |
| | TDI | D14 | I | TTL | JTAG TDI. |
| | TDO | C14 | O | TTL | JTAG TDO and SWO. |
| | TMS | C15 | I | TTL | JTAG TMS and SWDIO. |

Table 31-4. Signals by Function, Except for GPIO (continued)

| Function | Pin Name | Pin Number | Pin Type | Buffer Type | Description |
|----------|-----------|------------|----------|---|--|
| LCD | LCDAC | N1 | O | TTL | LCD AC bias or latch enable in Raster mode; Primary chip select (CS0)/Primary Enable (E0) in LIDD MPU/Hitachi mode |
| | LCDCP | N5 | O | TTL | LCD Pixel Clock in Raster mode; read strobe or read/write strobe in LIDD mode |
| | LCDDATA00 | P3 | I/O | TTL | LCD Data Pin 0 input/output. |
| | LCDDATA01 | P2 | I/O | TTL | LCD Data Pin 1 input/output. |
| | LCDDATA02 | U8 | I/O | TTL | LCD Data Pin 2 input/output. |
| | LCDDATA03 | V8 | I/O | TTL | LCD Data Pin 3 input/output. |
| | LCDDATA04 | W9 | I/O | TTL | LCD Data Pin 4 input/output. |
| | LCDDATA05 | R10 | I/O | TTL | LCD Data Pin 5 input/output. |
| | LCDDATA06 | V9 | I/O | TTL | LCD Data Pin 6 input/output. |
| | LCDDATA07 | T13 | I/O | TTL | LCD Data Pin 7 input/output. |
| | LCDDATA08 | U10 | I/O | TTL | LCD Data Pin 8 input/output. |
| | LCDDATA09 | R13 | I/O | TTL | LCD Data Pin 9 input/output. |
| | LCDDATA10 | W10 | I/O | TTL | LCD Data Pin 10 input/output. |
| | LCDDATA11 | V10 | I/O | TTL | LCD Data Pin 11 input/output. |
| | LCDDATA12 | U12 | I/O | TTL | LCD Data Pin 12 input/output. |
| | LCDDATA13 | T12 | I/O | TTL | LCD Data Pin 13 input/output. |
| | LCDDATA14 | H17 | I/O | TTL | LCD Data Pin 14 input/output. |
| | LCDDATA15 | F16 | I/O | TTL | LCD Data Pin 15 input/output. |
| | LCDDATA16 | F18 | O | TTL | LCD Data Pin 16 output. |
| | LCDDATA17 | E17 | O | TTL | LCD Data Pin 17 output. |
| | LCDDATA18 | E18 | O | TTL | LCD Data Pin 18 output. |
| | LCDDATA19 | F17 | O | TTL | LCD Data Pin 19 output. |
| | LCDDATA20 | D12 | O | TTL | LCD Data Pin 20 output. |
| | LCDDATA21 | D13 | O | TTL | LCD Data Pin 21 output. |
| | LCDDATA22 | B14 | O | TTL | LCD Data Pin 22 output. |
| | LCDDATA23 | A14 | O | TTL | LCD Data Pin 23 output. |
| LCDFP | N4 | O | TTL | LCD Frame Clock or VSYNC in Raster mode; Address Latch Enable in LIDD mode | |
| LCDLP | N2 | O | TTL | LCD Line Clock or HSYNC in Raster mode; Write Strobe or Direction bit in LIDD mode | |
| LCDMCLK | T8 | O | TTL | LCD Memory Clock/Secondary chip Select (CS1)/Secondary Enable (E1) in LIDD Synchronous/Async MPU/Hitachi mode | |

Table 31-4. Signals by Function, Except for GPIO (continued)

| Function | Pin Name | Pin Number | Pin Type | Buffer Type | Description |
|----------|----------|------------|----------|-------------|---|
| PWM | M0FAULT0 | V7 D12 | I | TTL | Motion Control Module 0 PWM Fault 0. |
| | M0FAULT1 | V16 D13 | I | TTL | Motion Control Module 0 PWM Fault 1. |
| | M0FAULT2 | W16 B14 | I | TTL | Motion Control Module 0 PWM Fault 2. |
| | M0FAULT3 | G16 A14 | I | TTL | Motion Control Module 0 PWM Fault 3. |
| | M0PWM0 | U6 N5 | O | TTL | Motion Control Module 0 PWM 0. This signal is controlled by Module 0 PWM Generator 0. |
| | M0PWM1 | V6 N4 | O | TTL | Motion Control Module 0 PWM 1. This signal is controlled by Module 0 PWM Generator 0. |
| | M0PWM2 | W6 N2 | O | TTL | Motion Control Module 0 PWM 2. This signal is controlled by Module 0 PWM Generator 1. |
| | M0PWM3 | T7 V8 | O | TTL | Motion Control Module 0 PWM 3. This signal is controlled by Module 0 PWM Generator 1. |
| | M0PWM4 | N15 P3 | O | TTL | Motion Control Module 0 PWM 4. This signal is controlled by Module 0 PWM Generator 2. |
| | M0PWM5 | T14 P2 | O | TTL | Motion Control Module 0 PWM 5. This signal is controlled by Module 0 PWM Generator 2. |
| | M0PWM6 | U19 W9 | O | TTL | Motion Control Module 0 PWM 6. This signal is controlled by Module 0 PWM Generator 3. |
| | M0PWM7 | V17 R10 | O | TTL | Motion Control Module 0 PWM 7. This signal is controlled by Module 0 PWM Generator 3. |

Table 31-4. Signals by Function, Except for GPIO (continued)

| Function | Pin Name | Pin Number | Pin Type | Buffer Type | Description | | | | | |
|----------|----------|------------|----------|-------------|---|------|-----|---|-------|---|
| Power | GND | F10 | - | Power | Ground reference for logic and I/O pins. | | | | | |
| | | H10 | | | | | | | | |
| | | H11 | | | | | | | | |
| | | H12 | | | | | | | | |
| | | J11 | | | | | | | | |
| Power | GND | J12 | - | Power | Ground reference for logic and I/O pins. | | | | | |
| | | K6 | | | | | | | | |
| | | K9 | | | | | | | | |
| | | P16 | | | | | | | | |
| | | K10 | | | | | | | | |
| | | R17 | | | | | | | | |
| | | K13 | | | | | | | | |
| | | K14 | | | | | | | | |
| | | L8 | | | | | | | | |
| | | L9 | | | | | | | | |

| | | K8 | | | | | | | | |
| | | K11 | | | | | | | | |
| | | N16 | | | | | | | | |
| | | P17 | | | | | | | | |
| | | K12 | | | | | | | | |
| | | L10 | | | | | | | | |
| | | L11 | | | | | | | | |
| | | L12 | | | | | | | | |
| | | M11 | | | | | | | | |
| | | M12 | | | | | | | | |
| | | P10 | | | | | | | | |
| | | Power | | | | VDDA | F3 | - | Power | The positive supply for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions. VDDA pins must be supplied with a voltage that meets the specification in , regardless of system implementation. |
| | | Power | | | | VDDC | H16 | - | Power | |
| E10 | | | | | | | | | | |

Table 31-4. Signals by Function, Except for GPIO (*continued*)

| Function | Pin Name | Pin Number | Pin Type | Buffer Type | Description |
|----------|----------|------------|----------|-------------|--|
| | | | | | Positive supply for most of the logic function, including the processor core and most peripherals. The voltage on this pin is 1.2 V and is supplied by the on-chip LDO. The V_{DDC} pins should only be connected to each other and an external capacitor as specified in Table 32-15 on page 2111 . |
| QE1 | IDX0 | J18 U10 | I | TTL | QE1 module 0 index. |
| | PhA0 | H19 V9 | I | TTL | QE1 module 0 phase A. |
| | PhB0 | G18 T13 | I | TTL | QE1 module 0 phase B. |

Table 31-4. Signals by Function, Except for GPIO (continued)

| Function | Pin Name | Pin Number | Pin Type | Buffer Type | Description |

| | U7Rx | M2 U2 | I | TTL | UART module 7 receive. |
| | U7Tx | M1 V2 | O | TTL | UART module 7 transmit. |

Table 31-4. Signals by Function, Except for GPIO (continued)

| Function | Pin Name | Pin Number | Pin Type | Buffer Type | Description |
|----------|----------|----------------|----------|--|---|
| USB | USB0CLK | B17 | O | TTL | 60-MHz clock to the external PHY. |
| | USB0D0 | G16 | I/O | TTL | USB data 0. |
| | USB0D1 | H19 | I/O | TTL | USB data 1. |
| | USB0D2 | G18 | I/O | TTL | USB data 2. |
| | USB0D3 | J18 | I/O | TTL | USB data 3. |
| | USB0D4 | H18 | I/O | TTL | USB data 4. |
| | USB0D5 | G19 | I/O | TTL | USB data 5. |
| | USB0D6 | B12 | I/O | TTL | USB data 6. |
| | USB0D7 | D8 | I/O | TTL | USB data 7. |
| | USB0DIR | C12 | O | TTL | Indicates that the external PHY is able to accept data from the USB controller. |
| | USB0DM | B18 | I/O | Analog | Bidirectional differential data pin (D- per USB specification) for USB0. |
| | USB0DP | C18 | I/O | Analog | Bidirectional differential data pin (D+ per USB specification) for USB0. |
| | USB0EPEN | V5 R7 B3 | O | TTL | Optionally used in Host mode to control an external power source to supply power to the USB bus. |
| | USB0ID | A16 | I | Analog | This signal senses the state of the USB ID signal. The USB PHY enables an integrated pull-up, and an external element (USB connector) indicates the initial state of the USB controller (pulled down is the A side of the cable and pulled up is the B side). |
| | USB0NXT | B13 | O | TTL | Asserted by the external PHY to throttle all data types. |
| | USB0PFLT | R7 B2 | I | TTL | Optionally used in Host mode by an external power source to indicate an error state by that power source. |
| USB0STP | A17 | O | TTL | Asserted by the USB controller to signal the end of a USB transmit packet or register write operation. | |
| USB0VBUS | B16 | I/O | Analog | This signal is used during the session request protocol. This signal allows the USB PHY to both sense the voltage level of VBUS, and pull up VBUS momentarily during VBUS pulsing. | |

31.4 GPIO Pins and Alternate Functions

Table 31-5. GPIO Pins and Alternate Functions

| IO | Pin | Analog or Special Function ^a | Digital Function (GPIO PCTL PMCx Bit Field Encoding) ^b | | | | | | | | | | | |
|-----|-----|---|---|---------|--------|---|---|---|--------|---|----|----|----|----------|

a. The TMPRn signals are digital signals enabled and configured by the Hibernation module. All other signals listed in this column are analog signals.

b. The digital signals that are shaded gray are the power-on default values for the corresponding GPIO pin. Encodings 9, 10, and 12 are not used on this device.

31.6 Connections for Unused Signals

Table 31-7 on page 2093 show how to handle signals for functions that are not used in a particular system implementation for devices that are in a 212-ball BGA package. Two options are shown in the table: an acceptable practice and a preferred practice for reduced power consumption and improved EMC characteristics. If a module is not used in a system, and its inputs are grounded, it is important that the clock to the module is never enabled by setting the corresponding bit in the **RCGCx** register.

Table 31-7. Connections for Unused Signals (212-Ball BGA)

| Function | Signal Name | Pin Number | Acceptable Practice | Preferred Practice |
|----------|------------------|------------|--|--------------------|
| ADC | VREFA+ | F4 | VDDA | VDDA |
| | VREFA- | G5 | GND | GND |
| Ethernet | EN0RXIN | V13 | NC | NC |
| | EN0RXIP | W13 | NC | NC |
| | EN0TXON | V14 | NC | NC |
| | EN0TXOP | V15 | NC | NC |
| | RBIAS | W15 | Connect to ground through 4.87K resistor | NC ^a |
| GPIO | PA1(UART0TX) | W3 | NC | GND ^b |
| | PA4(SSIOXDAT0) | V4 | NC | GND ^c |
| | All unused GPIOs | - | NC | GND |

Table 31-7. Connections for Unused Signals (212-Ball BGA) (continued)

| Function | Signal Name | Pin Number | Acceptable Practice | Preferred Practice |
|----------------|--------------------------|---|---------------------|--|
| Hibernate | GNDX | R18 | GND | GND |
| | HIB | M17 | NC | NC |
| | VBAT | P19 | NC | VDD |
| | $\overline{\text{WAKE}}$ | U18 | NC | GND |
| | XOSC0 | T18 | NC | GND |
| | XOSC1 | T19 | NC | NC |
| No Connects | NC | See NC pin numbers in Table 31-3 on page 2048 | NC | NC |
| System Control | GNDX2 | D18 | GND | GND |
| | OSC0 | E19 | NC | GND |
| | OSC1 | D19 | NC | NC |
| | $\overline{\text{RST}}$ | P18 | VDD | Pull up as shown in Figure 5-1 on page 235 |
| USB | USB0DM / PL7 | B18 | NC | Pull-down to GND with 1K resistor ^d |
| | USB0DP / PL6 | C18 | NC | Pull-down to GND with 1K resistor ^d |

- The internal Ethernet PHY should not be enabled when $\overline{\text{RBIAS}}$ is not connected. The ROM boot loader will enable the internal Ethernet PHY if no code is present in the flash and a 24-25 Mhz crystal is attached to the OSC0/OSC1 pins.
- PA1 (UART0TX) may be enabled as an output by the ROM boot loader if no code is present in the flash and PA0 (UART0RX) receives a valid boot signature. Ensure that this condition will not occur if PA1 is to be connected directly to GND.
- PA4 (SSIOXDAT0) may be enabled as an output by the ROM boot loader if no code is present in the flash and the SSIOX (PA2, PA3, PA5) receives a valid boot signature. Ensure that this condition will not occur if PA4 is to be connected directly to GND.
- The ROM boot loader may configure these pins as USB pins if no code is present in the flash therefore they should not be directly connected to ground.

32 Electrical Characteristics

32.1 Maximum Ratings

The maximum ratings are the limits to which the device can be subjected without permanently damaging the device. Device reliability may be adversely affected by exposure to absolute-maximum ratings for extended periods.

Note: The device is not guaranteed to operate properly at the maximum ratings.

Table 32-1. Absolute Maximum Ratings

| Parameter | Parameter Name ^a | Value | | Unit |
|-----------------------|---|-------|-----|------|
| | | Min | Max | |
| V _{DD} | V _{DD} supply voltage | 0 | 4 | V |
| V _{DDA} | V _{DDA} supply voltage | 0 | 4 | V |
| V _{BAT} | V _{BAT} battery supply voltage | 0 | 4 | V |
| V _{BATRMP} | V _{BAT} battery supply voltage ramp time | 0 | 0.7 | V/μs |
| V _{IN_GPIO} | Input voltage ^b | -0.3 | 4 | V |
| I _{GPIO MAX} | Maximum current per output pin | - | 64 | mA |
| T _S | Unpowered storage temperature range | -65 | 150 | °C |
| T _{JMAX} | Maximum junction temperature | - | 125 | °C |

a. Voltages are measured with respect to GND.

b. Applies to static and dynamic signals including overshoot.

Important: This device contains circuitry to protect the I/Os against damage due to high-static voltages; however, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum-rated voltages to this high-impedance circuit. Reliability of operation is enhanced if unused inputs are connected to an appropriate logic voltage level (see “Connections for Unused Signals” on page 2093).

Table 32-2. ESD Absolute Maximum Ratings

| Parameter | Parameter Name | Min | Nom | Max | Unit |
|---|----------------------------------|-----|-----|-----|------|
| Component-Level ESD Stress Voltage ^a | V _{ESDHBM} ^b | - | - | 2.0 | kV |
| | V _{ESDCDM} ^c | - | - | 500 | V |

a. Electrostatic discharge (ESD) is used to measure device sensitivity/immunity to damage caused by electrostatic discharges in device.

b. All pins are HBM compliant to 2 kV for all combinations as per JESD22-A114F, except for the following stress combinations:

- The Ethernet EN0RXIN, EN0TX0N, EN0RXIP, and EN0TXOP pins to each other.
- The GPIO pins PM4, PM5, PM6, and PM7 to other pins.

These exceptions are compliant to 500 V and do not require any special handling beyond typical ESD control procedures during assembly operations per JEDEC publication JEP155. Note that these pins do meet the 500 V CDM specification.

c. Level listed is the passing level per EIA-JEDEC JESD22-C101E. JEDEC document JEP157 states that 250 V CDM allows safe manufacturing with a standard ESD control process.

32.2 Operating Characteristics

Table 32-3. Temperature Characteristics

| Characteristic | Symbol | Value | Unit |
|--------------------------------------|--------|--|------|
| Ambient operating temperature range | T_A | -40 to 85 (industrial temperature part) -40 to 105 (extended temperature part) | °C |
| Junction operating temperature range | T_J | -40 to 105 (industrial temperature part) -40 to 125 (extended temperature part) | °C |

Table 32-4. 212 BGA Power Dissipation^{ab}

| Parameter | Parameter Name | T_A | T_J | Min | Max | Unit |
|-----------|---|-------------------------------------|--------------------------------------|-----|------|------|
| P_{DI} | Industrial temperature device power dissipation | 85 °C (industrial temperature part) | 125 °C (industrial temperature part) | - | 1018 | mW |
| P_{DE} | Extended temperature device power dissipation | 105 °C (extended temperature part) | 125 °C (extended temperature part) | - | 509 | mW |

- a. If the device exceeds the power dissipation value shown, then modifications such as heat sinks or fans must be used to conform to the limits shown.
- b. A larger power dissipation allowance can be achieved by lowering T_A as long as T_{JMAX} shown in Table 32-1 on page 2095 is not exceeded.

Table 32-5. Thermal Characteristics^a

| Characteristic | Symbol | Value | Unit |
|---|---------------|---|------|
| Thermal resistance (junction to ambient) ^b | Θ_{JA} | 39.3 | °C/W |
| Thermal resistance (junction to board) ^b | Θ_{JB} | 18.6 | °C/W |
| Thermal resistance (junction to case) ^b | Θ_{JC} | 12.9 | °C/W |
| Thermal metric (junction to top of package) | Ψ_{JT} | 0.2 | °C/W |
| Thermal metric (junction to board) | Ψ_{JB} | 18.4 | °C/W |
| Junction temperature formula | T_J | $T_C + (P \cdot \Psi_{JT})^c$ $T_{PCB} + (P \cdot \Psi_{JB})^d$ $T_A + (P \cdot \Theta_{JA})^e$ $T_B + (P \cdot \Theta_{JB})^{fg}$ | °C |

- a. For more details about thermal metrics and definitions, see the *Semiconductor and IC Package Thermal Metrics Application Report* (literature number [SPRA953](#)).
- b. Junction to ambient thermal resistance (Θ_{JA}), junction to board thermal resistance (Θ_{JB}), and junction to case thermal resistance (Θ_{JC}) numbers are determined by a package simulator.
- c. T_C is the case temperature and P is the device power consumption.
- d. T_{PCB} is the temperature of the board acquired by following the steps listed in the EAI/JESD 51-8 standard summarized in the *Semiconductor and IC Package Thermal Metrics Application Report* (literature number [SPRA953](#)). P is the device power consumption.
- e. Because Θ_{JA} is highly variable and based on factors such as board design, chip/pad size, altitude, and external ambient temperature, it is recommended that equations containing Ψ_{JT} and Ψ_{JB} be used for best results.
- f. T_B is temperature of the board.
- g. Θ_{JB} is not a pure reflection of the internal resistance of the package because it includes the resistance of the testing board and environment. It is recommended that equations containing Ψ_{JT} and Ψ_{JB} be used for best results.

32.3 Recommended Operating Conditions

The following sections describe the recommended DC operating conditions and GPIO operating characteristics for the device.

32.3.1 DC Operating Conditions

Table 32-6. Recommended DC Operating Conditions

| Parameter | Parameter Name | Min | Nom | Max | Unit |
|-------------------------------|--|------|-----|------|------|
| V _{DD} | V _{DD} supply voltage | 2.97 | 3.3 | 3.63 | V |
| V _{DDA} ^a | V _{DDA} supply voltage | 2.97 | 3.3 | 3.63 | V |
| V _{DDC} | V _{DDC} supply voltage, Run mode | 1.14 | 1.2 | 1.32 | V |
| V _{DDCDS} | V _{DDC} supply voltage, Deep-Sleep mode | 0.85 | - | 0.95 | V |

a. To ensure proper operation, V_{DDA} must be powered up before V_{DD} if sourced from different supplies, or connected to the same supply as V_{DD}. There is not a restriction on order for powering off.

32.3.2 Recommended GPIO Operating Characteristics

Two types of pads are provided on the device:

- Fast GPIO pads: These pads provide variable, programmable drive strength and optimized voltage output levels.
- Slow GPIO pads: These pads provide 2-mA drive strength and are designed to be sensitive to voltage inputs. The following GPIOs port pins are designed with Slow GPIO Pads:
 - PJ1

All other GPIOs have a fast GPIO pad-type.

Note: Port pins PL6 and PL7 operate as Fast GPIO pads, but have 4-mA drive capability only. GPIO register controls for drive strength, slew rate and open drain have no effect on these pins. The registers which have no effect are as follows: **GPIODR2R**, **GPIODR4R**, **GPIODR8R**, **GPIODR12R**, **GPIOSLR**, and **GPIOODR**.

Note: Port pins PM[7:4] operate as Fast GPIO pads but support only 2-, 4-, 6-, and 8-mA drive capability. 10- and 12-mA drive are not supported. All standard GPIO register controls, except for the **GPIODR12R** register, apply to these port pins.

Table 32-7 on page 2097 detail the GPIO operating conditions for these two different pad types.

Table 32-7. Recommended FAST GPIO Pad Operating Conditions

| Parameter | Parameter Name | Min | Nom | Max | Unit |
|------------------|---|------------------------|-----|------------------------|------|
| V _{IH} | Fast GPIO high-level input voltage | 0.65 * V _{DD} | - | 4 | V |
| I _{IH} | Fast GPIO high-level input current ^a | - | - | 300 | nA |
| V _{IL} | Fast GPIO low-level input voltage | 0 | - | 0.35 * V _{DD} | V |
| I _{IL} | Fast GPIO low-level input current ^a | - | - | -200 | nA |
| V _{HYS} | Fast GPIO Input Hysteresis | 0.49 | - | - | V |
| V _{OH} | Fast GPIO High-level output voltage | 2.4 | - | - | V |
| V _{OL} | Fast GPIO Low-level output voltage | - | - | 0.40 | V |

Table 32-7. Recommended FAST GPIO Pad Operating Conditions (continued)

| Parameter | Parameter Name | Min | Nom | Max | Unit |
|-----------|--|------|-----|-----|------|
| I_{OH} | Fast GPIO High-level source current, $V_{OH}=2.4\text{ V}^b$ | | | | |
| | 2-mA Drive | 2.0 | - | - | mA |
| | 4-mA Drive | 4.0 | - | - | mA |
| | 8-mA Drive | 8.0 | - | - | mA |
| | 10-mA Drive | 10.0 | - | - | mA |
| | 12-mA Drive | 12.0 | - | - | mA |
| I_{OL} | Fast GPIO Low-level sink current, $V_{OL}=0.4\text{ V}^b$ | | | | |
| | 2-mA Drive | 2.0 | - | - | mA |
| | 4-mA Drive | 4.0 | - | - | mA |
| | 8-mA Drive | 8.0 | - | - | mA |
| | 10-mA Drive | 10.0 | - | - | mA |
| | 12-mA Drive | 12.0 | - | - | mA |
| | 12-mA Drive overdriven to 18-mA | 18.0 | - | - | mA |

a. Output/pull-up/pull-down disabled; only input enabled

b. I_O specifications reflect the maximum current where the corresponding output voltage meets the V_{OH}/V_{OL} thresholds. I_O current can exceed these limits (subject to absolute maximum ratings).

Table 32-8. Recommended Slow GPIO Pad Operating Conditions

| Parameter | Parameter Name | Min | Nom | Max | Unit |
|-----------|--|-----------------|-----|-----------------|------|
| V_{IH} | Slow GPIO high-level input voltage | $0.65 * V_{DD}$ | - | 4 | V |
| I_{IH} | Slow GPIO high-level input current ^a | - | - | 4.1 | nA |
| V_{IL} | Slow GPIO low-level input voltage | 0 | - | $0.35 * V_{DD}$ | V |
| I_{IL} | Slow GPIO low-level input current ^a | - | - | -1 | nA |
| V_{HYS} | Slow GPIO Input Hysteresis | 0.49 | - | - | V |
| V_{OH} | Slow GPIO High-level output voltage | 2.4 | - | - | V |
| V_{OL} | Slow GPIO Low-level output voltage | - | - | 0.4 | V |
| I_{OH} | High-level source current, $V_{OH}=2.4\text{ V}^b$ | | | | |
| | 2-mA Drive | 2.0 | - | - | mA |
| I_{OL} | Low-level sink current, $V_{OL}=0.4\text{ V}^b$ | | | | |
| | 2-mA Drive | 2.0 | - | - | mA |

a. Output/pull-up/pull-down disabled; only input enabled.

b. I_O specifications reflect the maximum current where the corresponding output voltage meets the V_{OH}/V_{OL} thresholds. I_O current can exceed these limits (subject to absolute maximum ratings).

32.3.2.1 GPIO Current Restrictions

Table 32-9. GPIO Current Restrictions^a

| Parameter | Parameter Name | Min | Nom | Max | Unit |
|------------|---|-----|-----|-----|------|
| I_{MAXL} | Cumulative maximum GPIO current per side, left ^b | - | - | 110 | mA |
| I_{MAXB} | Cumulative maximum GPIO current per side, bottom ^b | - | - | 116 | mA |
| I_{MAXR} | Cumulative maximum GPIO current per side, right ^b | - | - | 110 | mA |

Table 32-9. GPIO Current Restrictions (continued)

| Parameter | Parameter Name | Min | Nom | Max | Unit |
|------------|--|-----|-----|-----|------|
| I_{MAXT} | Cumulative maximum GPIO current per side, top ^b | - | - | 88 | mA |

a. Based on design simulations, not tested in production.

b. Sum of sink and source current for GPIOs as shown in Table 32-10 on page 2099.

Table 32-10. Maximum GPIO Package Side Assignments

| Side | GPIOs |
|--------|---|
| Left | PB[6-7], PC[4-7], PD[0-3], PE[0-3], PH[0-7], PJ[6-7], PK[0-3], PQ[0-3,7], PR[0-5] |
| Bottom | PA[0-7], PF[0-7], PG[0-7], PK[4-7], PN[6-7], PR[3,6-7], PQ[5-6], PS[4-7], PT[0-1] |
| Right | PB[0-3], PJ[2-5], PL[0-5,6-7], PM[0-7], PT[2-3] |
| Top | PB[4-5], PC[0-3], PD[4-7], PE[4-7], PJ[0-1], PN[0-5], PP[0-7], PQ[4], PS[0-3], |

I/O Reliability

For typical continuous drive applications, I/O pins configured between 2 mA and 12 mA and operating at -40 to 85°C, meet the standard 10-year lifetime reliability. If a continuous current sink of 18 mA is required, then operation is limited to 0 to 75°C in order to meet the standard 10-year reliability.

At 105°C, I/O configured for continuous drive meet the standard 2.5 year lifetime reliability.

In typical switching applications (40% switch rate) operating at -40 to 85°C, all I/O configurations except 2 mA meet the standard 10-year lifetime reliability with 50-pF loading. By limiting the capacitive loading to 20 pF for an I/O configured to 2 mA, the 10-year lifetime reliability can be met at -40 to 85°C.

In typical switching applications (40% switch rate) operating at 105°C, all I/O configurations except 2 mA meet the standard 2.5-year lifetime reliability. By reducing the capacitive loading to 20 pF with a typical switching rate at 105°C, a 2-mA I/O configuration meets a 2.5 year lifetime reliability.

32.4 Load Conditions

Table 32-11 on page 2100 contains the load conditions used for timing measurements.

Figure 32-1. Load Conditions

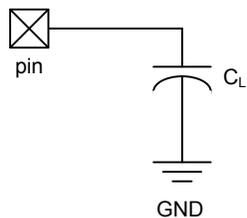

Table 32-11. Load Conditions

| Signals | Load Value (C _L) |
|---------------------------------------|------------------------------|
| LCDDATA[23:0] | 25 pF |
| EPIOS[35:0] SDRAM interface | 30 pF |
| EPIOS[35:0] General-Purpose interface | |
| EPIOS[35:0] Host-Bus interface | |
| EPIOS[35:0] PSRAM interface | 40 pF |
| All other digital I/O signals | 50 pF |

32.5 JTAG and Boundary Scan

Table 32-12. JTAG Characteristics

| Parameter No. | Parameter | Parameter Name | Min | Nom | Max | Unit |
|---------------|-----------------|---|-----|-------------|-----|------|
| J1 | F_{TCK} | TCK operational clock frequency ^a | 0 | - | 10 | MHz |
| J2 | T_{TCK} | TCK operational clock period | 100 | - | - | ns |
| J3 | T_{TCK_LOW} | TCK clock Low time | - | $t_{TCK}/2$ | - | ns |
| J4 | T_{TCK_HIGH} | TCK clock High time | - | $t_{TCK}/2$ | - | ns |
| J5 | T_{TCK_R} | TCK rise time | 0 | - | 10 | ns |
| J6 | T_{TCK_F} | TCK fall time | 0 | - | 10 | ns |
| J7 | T_{TMS_SU} | TMS setup time to TCK rise | 8 | - | - | ns |
| J8 | T_{TMS_HLD} | TMS hold time from TCK rise | 4 | - | - | ns |
| J9 | T_{TDI_SU} | TDI setup time to TCK rise | 18 | - | - | ns |
| J10 | T_{TDI_HLD} | TDI hold time from TCK rise | 4 | - | - | ns |
| J11 | T_{TDO_ZDV} | TCK fall to Data Valid from High-Z, 2-mA drive | - | 13 | 35 | ns |

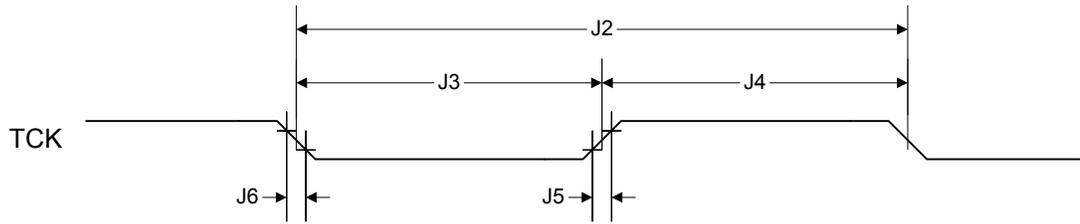

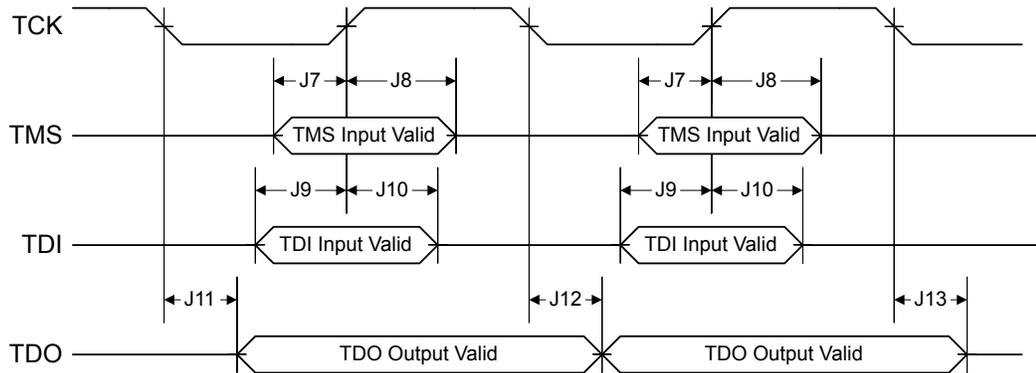

Figure 32-3. JTAG Test Access Port (TAP) Timing

32.6 Power and Brown-Out

Table 32-13. Power and Brown-Out Levels

| Parameter No. | Parameter | Parameter Name | Min | Nom | Max | Unit |
|---------------|--------------------|---|------|------|----------|---------|
| P1 | T_{VDDA_RISE} | Analog Supply voltage (V_{DDA}) rise time | - | - | ∞ | μs |
| P2 | T_{VDD_RISE} | I/O Supply voltage (V_{DD}) rise time | - | - | ∞ | μs |
| P3 | $T_{VDDC_RISE}^a$ | Core Supply Voltage (V_{DDC}) rise time | 10 | - | 150 | μs |
| P4 | V_{POR} | Power-On Reset Threshold (Rising Edge) | 1.98 | 2.35 | 2.72 | V |
| | | Power-On Reset Threshold (Falling Edge) | 1.84 | 2.20 | 2.56 | V |
| | | Power-On Reset Hysteresis | 0.06 | 0.15 | 0.24 | V |
| P5 | V_{DDA_POK} | V_{DDA} Power-OK Threshold (Rising Edge) | 2.67 | 2.82 | 2.97 | V |
| P6 | V_{DDA_BOR0} | V_{DDA} Brown-Out Reset Threshold | 2.71 | 2.80 | 2.89 | V |
| P7 | V_{DD_POK} | V_{DD} Power-OK Threshold (Rising Edge) | 2.65 | 2.80 | 2.90 | V |
| | | V_{DD} Power-OK Threshold (Falling Edge) | 2.67 | 2.76 | 2.85 | V |
| P8 | V_{DD_BOR0} | V_{DD} Brown-Out Reset Threshold | 2.77 | 2.86 | 2.95 | V |
| P9 | V_{DDC_POK} | V_{DDC} Power-OK Threshold (Rising Edge) | 0.85 | 0.95 | 1.10 | V |
| | | V_{DDC} Power-OK Threshold (Falling Edge) | 0.71 | 0.80 | 0.85 | V |

a. The MIN and MAX values are based on an external filter capacitor load within the range of C_{LDO} . Please refer to "On-Chip Low Drop-Out (LDO) Regulator" on page 2111 for the C_{LDO} value.

32.6.1 V_{DDA} Levels

The V_{DDA} supply has three monitors:

- Power-On Reset (POR)
- Power-OK (POK)
- Brown Out Reset (BOR)

The POR monitor is used to keep the analog circuitry in reset until the V_{DDA} supply has reached the correct range for the analog circuitry to begin operating. The POK monitor is used to keep the digital circuitry in reset until the V_{DDA} power supply is at an acceptable operational level. The digital reset is only released when the Power-On Reset has deasserted and all of the Power-OK monitors for each of the supplies indicate that power levels are in operational ranges. The BOR monitor is used to generate a reset to the device or assert an interrupt if the V_{DDA} supply drops below its operational range.

Note: V_{DDA} BOR and V_{DD} BOR events are a combined BOR to the system logic, such that if either BOR event occurs, the following bits are affected:

- BORRIS bit in the **Raw Interrupt Status (RIS)** register, System Control offset 0x050. See page 273.
- BORMIS bit in the **Masked Interrupt Status and Clear (MISC)** register, System Control offset 0x058. This bit is set only if the BORIM bit in the **Interrupt Mask Control (IMC)** register has been set. See page 275 and page 277.

- BOR bit in the **Reset Cause (RESC)** register, System Control offset 0x05C. This bit is set only if either of the BOR events have been configured to initiate a reset. See page 279.

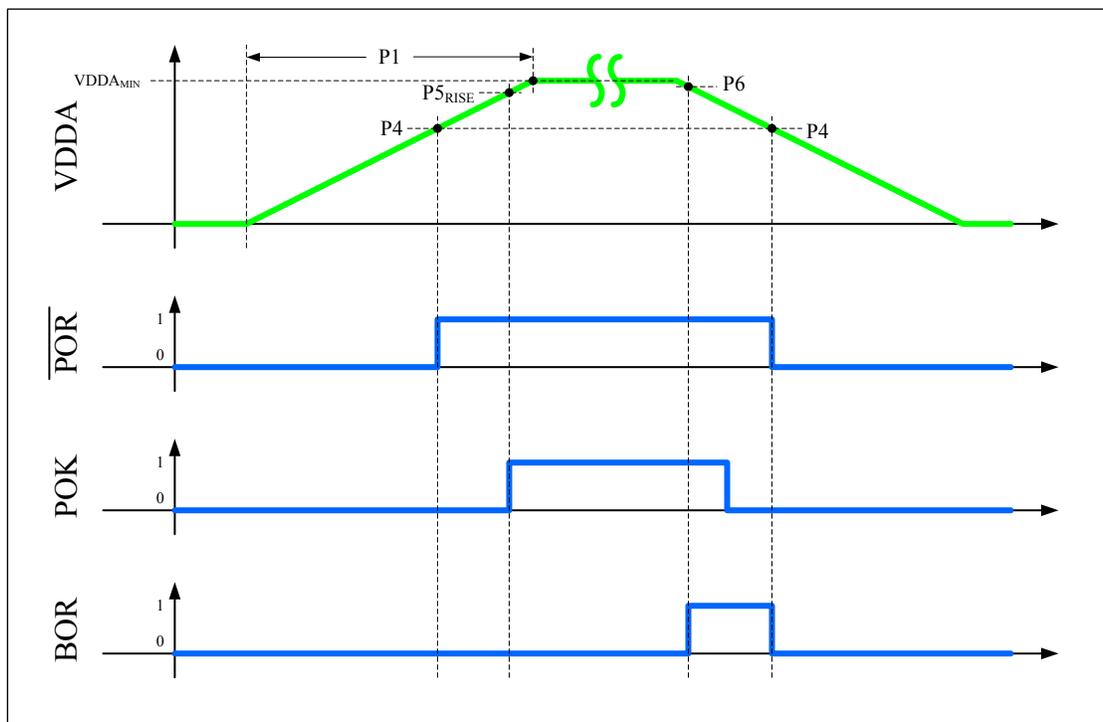

In addition, the following bits control both BOR events:

- BORIM bit in the **Interrupt Mask Control (IMC)** register, System Control offset 0x054.
- VDDA_UBOR0 and VDD_UBOR0 bits in the **Power-Temperature Cause (PWRTC)** register.

Please refer to “System Control” on page 231 for more information on how to configure these registers.

Figure 32-4 on page 2104 shows the relationship between V_{DDA} , POK, POR and a BOR event.

Figure 32-4. Power and Brown-Out Assertions vs V_{DDA} Levels

32.6.2 V_{DD} Levels

The V_{DD} supply has two monitors:

- Power-OK (POK)
- Brown Out Reset (BOR)

The POK monitor is used to keep the digital circuitry in reset until the V_{DD} power supply is at an acceptable operational level. The digital reset is only released when the Power-On Reset has deasserted and all of the Power-OK monitors for each of the supplies indicate that power levels are

in operational ranges. The BOR monitor is used to generate a reset to the device or assert an interrupt if the V_{DD} supply drops below its operational range.

Note: V_{DDA} BOR and V_{DD} BOR events are a combined BOR to the system logic, such that if either BOR event occurs, the following bits are affected:

- BORRIS bit in the **Raw Interrupt Status (RIS)** register, System Control offset 0x050. See page 273.
- BORMIS bit in the **Masked Interrupt Status and Clear (MISC)** register, System Control offset 0x058. This bit is set only if the BORIM bit in the **Interrupt Mask Control (IMC)** register has been set. See page 275 and page 277.
- BOR bit in the **Reset Cause (RESC)** register, System Control offset 0x05C. This bit is set only if either of the BOR events have been configured to initiate a reset. See page 279.

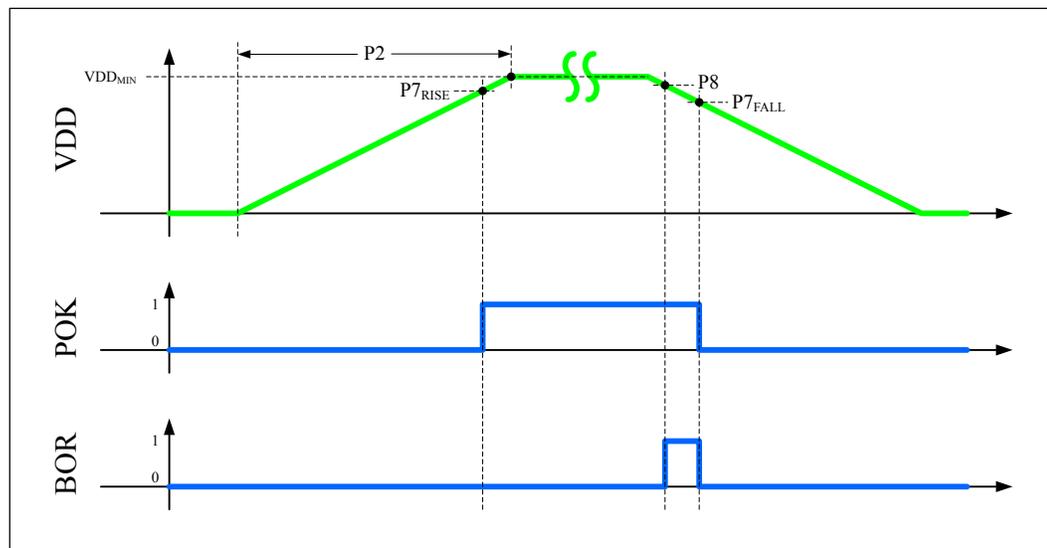

In addition, the following bits control both BOR events:

- BORIM bit in the **Interrupt Mask Control (IMC)** register, System Control offset 0x054.
- VDDA_UBOR0 and VDD_UBOR0 bits in the **Power-Temperature Cause (PWRTC)** register.

Please refer to “System Control” on page 231 for more information on how to configure these registers.

Figure 32-5 on page 2105 shows the relationship between V_{DD} , POK, POR and a BOR event.

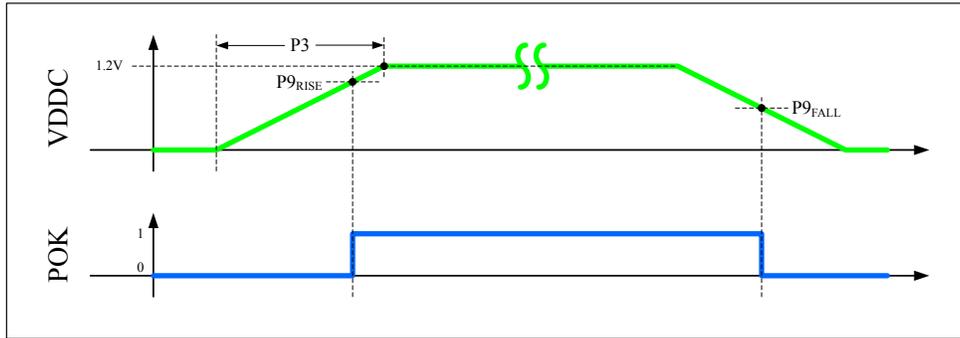

Figure 32-5. Power and Brown-Out Assertions vs V_{DD} Levels

32.6.3 V_{DDC} Levels

The V_{DDC} supply has one monitor, the Power-OK (POK). The POK monitor is used to keep the digital circuitry in reset until the V_{DDC} power supply is at an acceptable operational level. The digital reset is only released when the Power-On Reset has deasserted and all of the Power-OK monitors for each of the supplies indicate that power levels are in operational ranges. Figure 32-6 on page 2106 shows the relationship between POK and V_{DDC} .

Figure 32-6. POK Assertion vs V_{DDC}

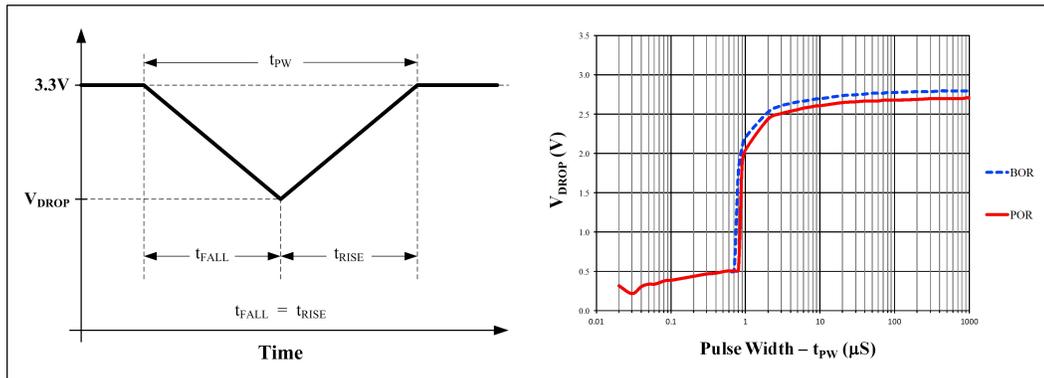

32.6.4 Response

32.6.4.1 V_{DD} Glitch Response

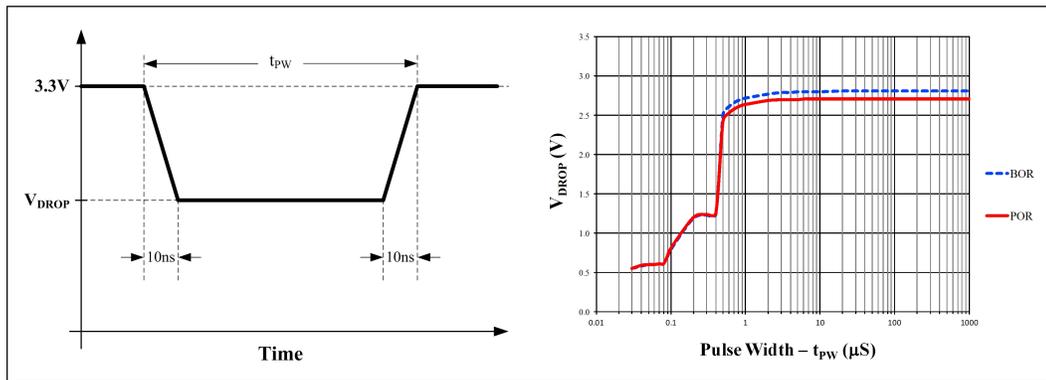

Figure 32-7 on page 2106 shows the response of the BOR and the POR circuit to glitches on the VDD supply.

Figure 32-7. POR-BOR V_{DD} Glitch Response

32.6.4.2 V_{DD} Droop Response

Figure 32-8 on page 2107 shows the response of the BOR and the POR monitors to a drop on the VDD supply.

Figure 32-8. POR-BOR V_{DD} Droop Response

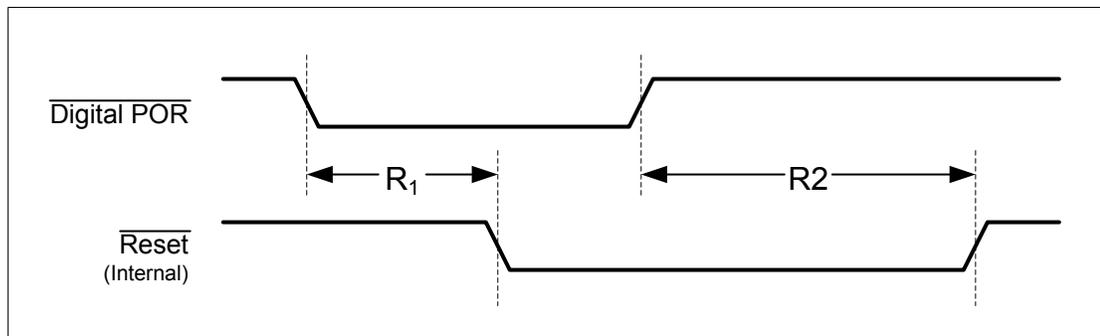

32.7 Reset

Table 32-14. Reset Characteristics^a

| Parameter No. | Parameter | Parameter Name | Min | Nom | Max | Unit |
|---------------|------------------|---|------|-------------------------------------|-------------------|---------------|
| R1 | $T_{DPORDLY}^b$ | Digital POR to Internal Reset assertion delay ^c | 0.44 | - | 126 | μs |
| R2 | T_{IRTOU}^{bd} | Standard Internal Reset time | - | 14 | 16 | ms |
| | | Internal Reset time with recovery code repair (program or erase) ^e | 24.4 | - | 6400 ^f | ms |
| R3 | $T_{BOROPLY}^b$ | BOR0 to Internal Reset assertion delay ^c | 0.44 | - | 125 | μs |
| R4 | T_{RSTMIN} | Minimum $\overline{\text{RST}}$ pulse width | - | 0.25 ^g /100 ^h | - | μs |
| R5 | $T_{IRHWDLY}^b$ | $\overline{\text{RST}}$ to Internal Reset assertion delay | - | 0.85 | - | μs |
| R6 | T_{IRSWR}^b | Internal reset timeout after software-initiated system reset | - | 2.44 | - | μs |
| R7 | T_{IRWDR}^b | Internal reset timeout after Watchdog reset | - | 2.44 | - | μs |
| R8 | T_{IRMFR}^b | Internal reset timeout after MOSC failure reset | - | 2.44 | - | μs |

- a. Minimum timings are for reset assertion using PIOSC as a clock source. Maximum timings are for reset assertion using LFIOSC in Deep-Sleep Operation.
- b. These values are based on simulation.
- c. Timing values are dependent on the V_{DD} power-down ramp rate.
- d. This is the delay from the time POR is released until the reset vector is fetched.
- e. This parameter applies only in situations where a power-loss or brown-out event occurs during an EEPROM program or erase operation, and EEPROM needs to be repaired (which is a rare case). For all other sequences, there is no impact to normal Power-On Reset (POR) timing. This delay is in addition to other POR delays.
- f. This value represents the maximum internal reset time when the EEPROM reaches its endurance limit.
- g. Standard operation.
- h. Deep-Sleep operation with PIOSC powered down.

Figure 32-9. Digital Power-On Reset Timing

The digital Power-On Reset is only released when the analog Power-On Reset has deasserted and all of the Power-OK monitors for each of the supplies indicate that power levels are in operational ranges.

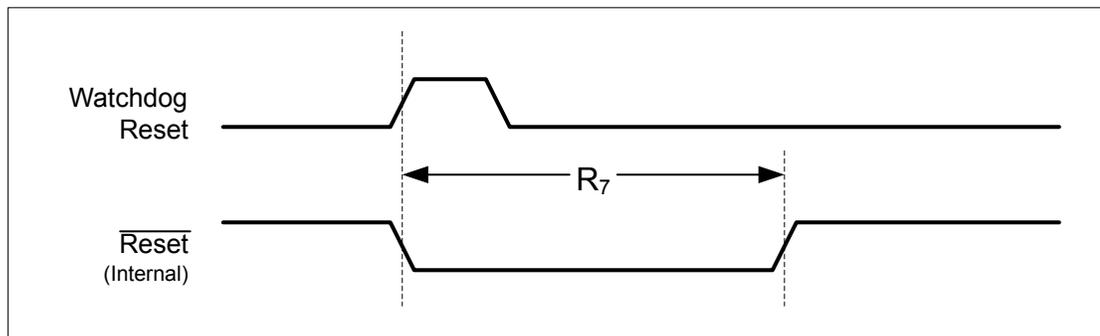

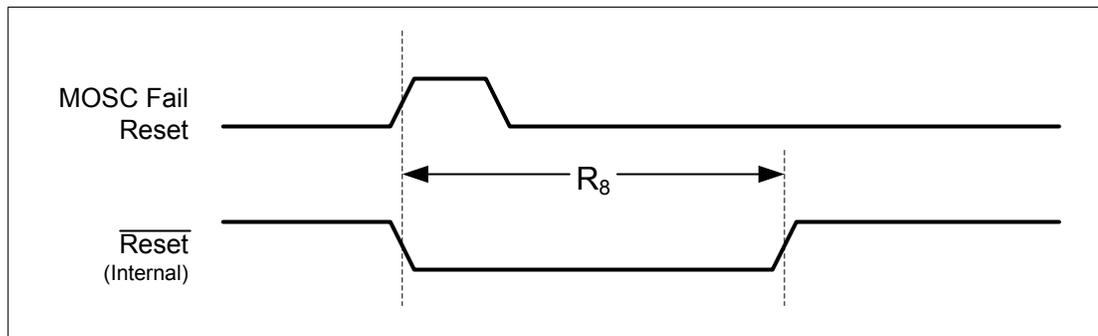

Figure 32-14. MOSC Failure Reset Timing

32.8 On-Chip Low Drop-Out (LDO) Regulator

Table 32-15. LDO Regulator Characteristics

| Parameter | Parameter Name | Min | Nom | Max | Unit |
|--------------|---|------|-----|------|------------------|
| C_{LDO} | External filter capacitor size for internal power supply ^a | 2.5 | - | 4.0 | μF |
| ESR | Filter capacitor equivalent series resistance | 0 | - | 100 | $\text{m}\Omega$ |
| ESL | Filter capacitor equivalent series inductance | - | - | 0.5 | nH |
| V_{LDO} | LDO output voltage, Run mode | 1.13 | 1.2 | 1.27 | V |
| I_{INRUSH} | Inrush current | 50 | - | 250 | mA |

a. The capacitor should be connected as close as possible to pin E10.

32.9 Clocks

The following sections provide specifications on the various clock sources and mode.

32.9.1 PLL Specifications

The following tables provide specifications for using the PLL.

Note: If the integrated Ethernet PHY is used in this device, then F_{REF_XTAL} and F_{REF_EXT} are required to be 25 MHz.

Table 32-16. Phase Locked Loop (PLL) Characteristics

| Parameter | Parameter Name | Min | Nom | Max | Unit |
|-----------------|--|-----|-----|--------------------------------|------|
| F_{REF_XTAL} | Crystal reference | 5 | - | 25 | MHz |
| F_{REF_EXT} | External clock reference | 5 | - | 25 | MHz |
| F_{PLL} | PLL VCO frequency at 1.2V ^a | - | - | 480 | MHz |
| F_{PLLS} | PLL VCO frequency at 0.9V ^b | - | - | 480 | MHz |
| T_{READY} | PLL lock time (enabling the PLL) when PLL is transitioning from power down to power up | - | - | 512 * (reference clock period) | μs |
| | PLL lock time when the PLL VCO frequency is changed (PLL is already enabled) | - | - | 128 * (reference clock period) | μs |
| | PLL lock time, changing the $OSCSRC$ between MOSC and PIOSC | - | - | 128 * (reference clock period) | μs |

a. PLL frequency is manually calculated using the values in the PLL_{FREQ0} and PLL_{FREQ1} registers.

b. If the LDO is dropped to 0.9V, the system must be run 1/4 of the maximum frequency at most. The Q value in the PLL_{FREQ1} register must be set to 0x3 rather than using the $PSYS_{DIV}$ field in the $RSCLKCFG$ register for the divisor.

32.9.1.1 PLL Configuration

The PLL is disabled by default during power-on reset and is enabled later by software if required. Software specifies the output divisor to set the system clock frequency and enables the PLL to drive the output. The PLL is controlled using the PLL_{FREQ0} , PLL_{FREQ1} and PLL_{STAT} registers. Changes made to these registers do not become active until after the NEW_{FREQ} bit in the $RSCLKCFG$ register is enabled.

The clock source for the main PLL is selected by configuring the $PLLSRC$ field in the **Run and Sleep Clock Configuration (RSCLKCFG)** register.

The PLL allows for the generation of system clock frequencies in excess of the reference clock provided. The reference clocks for the PLL are the PIOSC and the MOSC. The PLL is controlled by two registers, PLL_{FREQ0} and PLL_{FREQ1} . The PLL VCO frequency (f_{VCO}) is determined through the following calculation:

$$f_{VCO} = f_{IN} * MDIV$$

where

$$f_{IN} = f_{XTAL} / (Q+1)(N+1) \text{ or } f_{PIOSC} / (Q+1)(N+1)$$

$$MDIV = MINT + (MFRAC / 1024)$$

The Q and N values are programmed in the PLL_{FREQ1} register. Note that to reduce jitter, $MFRAC$ should be programmed to 0x0.

When the PLL is active, the system clock frequency (SysClk) is calculated using the following equation:

$$\text{SysClk} = f_{\text{VCO}} / (\text{PSYSDIV} + 1)$$

The PLL system divisor factor (PSYSDIV) determines the value of the system clock. Table 5-6 on page 249 shows how the system divisor encodings affect the system clock frequency when the $f_{\text{VCO}} = 480$ MHz.

Table 32-17. System Divisor Factors for $f_{\text{VCO}}=480$ MHz

| System Clock (SYSCLK) (MHz) | f_{VCO} (MHz)= 480 MHz |
|-----------------------------|---|
| | System Divisors ($\text{PSYSDIV} + 1$) ^a |
| 120 | 4 |
| 60 | 8 |
| 48 | 10 |
| 30 | 16 |
| 24 | 20 |
| 12 | 40 |
| 6 | 80 |

a. The use of non-integer divisors introduce additional jitter which may affect interface performance.

If the main oscillator provides the clock reference to the PLL, the translation provided by hardware and used to program the PLL is available for software in the **PLL Frequency n (PLLFREQn)** registers (see page 304). The internal translation provides a translation within $\pm 1\%$ of the targeted PLL VCO frequency. Table 5-7 on page 250 shows the actual PLL frequency and error for a given crystal choice.

Table 5-7 on page 250 provides examples of the programming expected for the **PLLREQ0** and **PLLREQ1** registers. The first column specifies the input crystal frequency and the last column displays the PLL frequency given the values of MINT and N , when $Q=0$.

Table 32-18. Actual PLL Frequency^a

| Crystal Frequency (MHz) | MINT (Decimal Value) | MINT (Hexadecimal Value) | N | Reference Frequency (MHz) ^b | PLL Frequency (MHz) |
|-------------------------|----------------------|--------------------------|-----|--|---------------------|
| 5 | 64 | 0x40 | 0x0 | 5 | 320 |
| 6 | 160 | 0x35 | 0x2 | 2 | 320 |
| 8 | 40 | 0x28 | 0x0 | 8 | 320 |
| 10 | 32 | 0x20 | 0x0 | 10 | 320 |
| 12 | 80 | 0x50 | 0x2 | 4 | 320 |
| 16 | 20 | 0x14 | 0x0 | 16 | 320 |
| 18 | 160 | 0xA0 | 0x8 | 2 | 320 |
| 20 | 16 | 0x10 | 0x0 | 20 | 320 |
| 24 | 40 | 0x28 | 0x2 | 8 | 320 |
| 25 | 64 | 0x40 | 0x4 | 5 | 320 |
| 5 | 96 | 0x60 | 0x0 | 5 | 480 |
| 6 | 80 | 0x50 | 0x0 | 6 | 480 |
| 8 | 60 | 0x3C | 0x0 | 8 | 480 |

Table 32-18. Actual PLL Frequency (continued)

| Crystal Frequency (MHz) | MINT (Decimal Value) | MINT (Hexadecimal Value) | N | Reference Frequency (MHz) ^b | PLL Frequency (MHz) |
|-------------------------|----------------------|--------------------------|-----|--|---------------------|
| 10 | 48 | 0x30 | 0x0 | 10 | 480 |
| 12 | 40 | 0x28 | 0x0 | 12 | 480 |
| 16 | 30 | 0x1E | 0x0 | 16 | 480 |
| 18 | 80 | 0x50 | 0x2 | 6 | 480 |
| 20 | 24 | 0x18 | 0x0 | 20 | 480 |
| 24 | 20 | 0x14 | 0x0 | 24 | 480 |
| 25 | 96 | 0x60 | 0x4 | 5 | 480 |

a. For all examples listed, Q=0

b. For a given crystal frequency, N should be chosen such that the reference frequency is within 4 to 30 MHz.

32.9.2 PIOSC Specifications

Table 32-19. PIOSC Clock Characteristics

| Parameter | Parameter Name | Min | Nom | Max | Unit |
|--------------------|--|-----|-----|-------|------|
| F _{PIOSC} | Factory calibration, 0 to +105°C: Internal 16-MHz precision oscillator frequency variance across voltage and temperature range when factory calibration is used | - | - | ±4.5% | - |
| | Factory calibration, -40°C to <0°C | - | - | ±10% | - |
| | Recalibration: Internal 16-MHz precision oscillator frequency variance when recalibration is used at a specific temperature | - | - | ±1% | - |
| T _{START} | PIOSC startup time ^a | - | - | 1 | μs |

a. PIOSC startup time is part of reset and is included in the internal reset timeout value (T_{IRTOU}) given in Table 32-14 on page 2108. Note that the T_{START} value is based on simulation.

32.9.3 Low-Frequency Internal Oscillator Specifications

Table 32-20. Low-Frequency Oscillator Characteristics

| Parameter | Parameter Name | Min | Nom | Max | Unit |
|---------------------|---|-----|-----|-----|------|
| F _{LFIOSC} | Internal low-frequency oscillator frequency | 10 | 33 | 75 | KHz |

32.9.4 Hibernation Clock Source Specifications

Table 32-21. Hibernation Internal Low Frequency Oscillator Clock Characteristics

| Parameter | Parameter Name | Min | Nom | Max | Unit |
|------------------------|---|-----|-----|-----|------|
| F _{HIBLFIOSC} | Internal Low Frequency Hibernation oscillator frequency | 10 | 33 | 90 | KHz |

Table 32-22. Hibernation External Oscillator (XOSC) Input Characteristics

| Parameter | Parameter Name | Min | Nom | Max | Unit |
|-----------------------------------|---|-----|--------|-----|------|
| F _{HIBXOSC} ^a | Parallel resonance frequency | - | 32.768 | - | KHz |
| C ₁ , C ₂ | External load capacitance on XOSC0, XOSC1 pins ^b | 12 | - | 24 | pF |
| C _{PKG} | Device package stray shunt capacitance ^b | - | 0.5 | - | pF |

Table 32-22. Hibernation External Oscillator (XOSC) Input Characteristics (continued)

| Parameter | Parameter Name | Min | Nom | Max | Unit |
|-------------------------------|--|--------------|-----|-------------------|------|
| C _{PCB} | PCB stray shunt capacitance ^b | - | 0.5 | - | pF |
| C _{SHUNT} | Total shunt capacitance ^b | - | - | 4 | pF |
| ESR | Crystal effective series resistance, OSCDRV = 0 ^c | - | - | 50 | kΩ |
| | Crystal effective series resistance, OSCDRV = 1 ^c | - | - | 75 | kΩ |
| DL | Oscillator output drive level | - | - | 0.25 | μW |
| T _{START} | Oscillator startup time, when using a crystal ^d | - | 600 | 1500 ^e | ms |
| V _{IH} ^f | CMOS input high level, when using an external oscillator with Supply > 3.3 V | 2.64 | - | - | V |
| | CMOS input high level, when using an external oscillator with 1.8 V ≤ Supply ≤ 3.3 V | 0.8 * Supply | - | - | V |
| V _{IL} ^f | CMOS input low level, when using an external oscillator with 1.8 V ≤ Supply ≤ 3.63 V | - | - | 0.2 * Supply | V |
| V _{HYS} ^f | CMOS input buffer hysteresis, when using an external oscillator with 1.8 V ≤ Supply ≤ 3.63 V | 360 | 960 | 1390 | mV |
| DC _{HIBOSC_EXT} | External single-Ended (Bypass) reference duty cycle | 30 | - | 70 | % |

a. The HIB XOSC pins are non-failsafe and must follow the limits detailed in “Non-Power I/O Pins” on page 2128.

b. See information below table.

c. Crystal ESR specified by crystal manufacturer.

d. Oscillator startup time is specified from the time the oscillator is enabled to when it reaches a stable point of oscillation such that the internal clock is valid.

e. Only valid for recommended supply conditions. Measured with OSCDRV bit set (high drive strength enabled, 24 pF).

f. Specification is relative to the larger of V_{DD} or V_{BAT}.

The load capacitors added on the board, C₁ and C₂, should be chosen such that the following equation is satisfied (see Table 32-22 on page 2114 for typical values).

- C_L = load capacitance specified by crystal manufacturer
- $C_L = (C_1 * C_2) / (C_1 + C_2) + C_{PKG} + C_{PCB}$
- C_{SHUNT} = C_{PKG} + C_{PCB} + C₀ (total shunt capacitance seen across XOSC0, XOSC1)
- C_{PKG}, C_{PCB} as measured across the XOSC0, XOSC1 pins excluding the crystal
- Clear the OSCDRV bit in the **Hibernation Control (HIBCTL)** register for C_{1,2} ≤ 18 pF; set the OSCDRV bit for C_{1,2} > 18 pF.
- C₀ = Shunt capacitance of crystal specified by the crystal manufacturer

32.9.5 Main Oscillator Specifications

Table 32-23. Main Oscillator Input Characteristics^a

| Parameter | Parameter Name | Min | Nom | Max | Unit |
|---------------------------------|---|----------------|-----|-----|------|
| F _{MOSC} | Parallel resonance frequency | 4 ^b | - | 25 | MHz |
| F _{REF_XTAL_BYPASS} | External clock reference (PLL in BYPASS mode) | 0 | - | 120 | MHz |
| C ₁ , C ₂ | External load capacitance on osc0, osc1 pins ^c | 12 | - | 24 | pF |
| C _{PKG} | Device package stray shunt capacitance ^c | - | 0.5 | - | pF |

Table 32-23. Main Oscillator Input Characteristics (continued)

| Parameter | Parameter Name | Min | Nom | Max | Unit |
|-----------------------|---|------------------------|--------------------|------------------------|------|
| C _{PCB} | PCB stray shunt capacitance ^c | - | 0.5 | - | pF |
| C _{SHUNT} | Total shunt capacitance ^c | - | - | 4 | pF |
| ESR | Crystal effective series resistance, 4 MHz ^{de} | - | - | 300 | Ω |
| | Crystal effective series resistance, 6 MHz ^{de} | - | - | 200 | Ω |
| | Crystal effective series resistance, 8 MHz ^{de} | - | - | 130 | Ω |
| | Crystal effective series resistance, 12 MHz ^{de} | - | - | 120 | Ω |
| | Crystal effective series resistance, 16 MHz ^{de} | - | - | 100 | Ω |
| | Crystal effective series resistance, 25 MHz ^{de} | - | - | 50 | Ω |
| DL | Oscillator output drive level ^f | - | OSC _{PWR} | - | mW |
| T _{START} | Oscillator startup time, when using a crystal ^g | - | - | 18 | ms |
| V _{IH} | CMOS input high level, when using an external oscillator | 0.65 * V _{DD} | - | V _{DD} | V |
| V _{IL} | CMOS input low level, when using an external oscillator | GND | - | 0.35 * V _{DD} | V |
| V _{HYS} | CMOS input buffer hysteresis, when using an external oscillator | 150 | - | - | mV |
| DC _{OSC_EXT} | External clock reference duty cycle | 45 | - | 55 | % |

a. Refer to Table 32-50 on page 2148 and Table 32-51 on page 2148 for additional Ethernet crystal requirements.

b. 5 MHz is the minimum when using the PLL.

c. See information below table.

d. Crystal ESR specified by crystal manufacturer.

e. Crystal vendors can be contacted to confirm these specifications are met for a specific crystal part number if the vendors generic crystal datasheet show limits outside of these specifications.

f. $OSC_{PWR} = (2 * \pi * F_p * C_L * 2.5)^2 * ESR / 2$. An estimation of the typical power delivered to the crystal is based on the C_L, F_p and ESR parameters of the crystal in the circuit as calculated by the OSC_{PWR} equation. Ensure that the value calculated for OSC_{PWR} does not exceed the crystal's drive-level maximum.

g. Oscillator startup time is specified from the time the oscillator is enabled to when it reaches a stable point of oscillation such that the internal clock is valid.

The load capacitors added on the board, C₁ and C₂, should be chosen such that the following equation is satisfied (see Table 32-23 on page 2115 for typical values and Table 32-24 on page 2117 for detailed crystal parameter information).

- C_L = load capacitance specified by crystal manufacturer
- $C_L = (C_1 * C_2) / (C_1 + C_2) + C_{SHUNT}$
- C_{SHUNT} = C₀ + C_{PKG} + C_{PCB} (total shunt capacitance seen across OSC0, OSC1 crystal inputs)
- C_{PKG}, C_{PCB} = the mutual caps as measured across the OSC0, OSC1 pins excluding the crystal.
- C₀ = Shunt capacitance of crystal specified by the crystal manufacturer

Table 32-24 on page 2117 lists part numbers of crystals that have been simulated and confirmed to operate within the specifications in Table 32-23 on page 2115. Other crystals that have nearly identical crystal parameters can be expected to work as well.

In the table below, the crystal parameters labeled C0, C1 and L1 are values that are obtained from the crystal manufacturer. These numbers are usually a result of testing a relevant batch of crystals

on a network analyzer. The parameters labeled ESR, DL and C_L are maximum numbers usually available in the data sheet for a crystal.

The table also includes three columns of Recommended Component Values. These values apply to system board components. C_1 and C_2 are the values in pico Farads of the load capacitors that should be put on each leg of the crystal pins to ensure oscillation at the correct frequency. R_s is the value in $k\Omega$ of a resistor that is placed in series with the crystal between the OSC1 pin and the crystal pin. R_s dissipates some of the power so the Max DI crystal parameter is not exceeded. Only use the recommended C_1 , C_2 , and R_s values with the associated crystal part. The values in the table were used in the simulation to ensure crystal startup and to determine the worst case drive level (WC DI). The value in the WC DI column should not be greater than the Max DI Crystal parameter. The WC DI value can be used to determine if a crystal with similar parameter values but a lower Max DI value is acceptable.

Table 32-24. Crystal Parameters

| MFG | MFG Part# | Holder | PKG Size (mm x mm) | Freq (MHz) | Crystal Spec (Tolerance / Stability) | Crystal Parameters | | | | | | Recommended Component Values | | | WC DI (μ W) |

a. R_S values as low as 0 Ohms can be used. Using a lower R_S value will result in the WC DL to increase towards the Max DL of the crystal.

b. Although this ESR value is outside of the recommended crystal ESR maximum for this frequency, this crystal has been simulated to confirm proper operation and is valid for use with this device.

c. R_S values as low as 500 Ohms can be used. Using a lower R_S value will result in the WC DL to increase towards the Max DL of the crystal.

32.9.6 System Clock Specification with ADC Operation

Table 32-25. System Clock Characteristics with ADC Operation

| Parameter | Parameter Name | Min | Nom | Max | Unit |
|---------------------|---|-----|-----|-----|------|
| F_{sysadc} | System clock frequency when the ADC module is operating (when PLL is bypassed). | - | 16 | - | MHz |

32.9.7 System Clock Specification with USB Operation

Table 32-26. System Clock Characteristics with USB Operation

| Parameter | Parameter Name | Min | Nom | Max | Unit |
|---------------------|---|-----|-----|-----|------|
| F_{sysusb} | System clock frequency when the USB module is operating (note that MOSC must be the clock source, either with or without using the PLL) | 30 | - | - | MHz |

32.10 Sleep Modes

The following tables can be used to calculate the maximum wake time from Sleep or Deep Sleep depending on the specific application. Depending on the application configuration, each of the parameters, except for T_{FLASH} , add sequential latency to the wake time. Flash restoration happens in parallel to the other wake processes and its wake time is normally absorbed by the other latencies. As an example, the wake time for a device in Deep Sleep, with the PIOSC and PLL turned off and the Flash and SRAM in low power mode is calculated as follows:

$$\text{Wake Time} = T_{PIOSCDS} + T_{PLLDS} + T_{SRAML PDS}$$

T_{FLASH} does not contribute to this equation since all other parameters are greater in value.

Note that in Sleep mode the wake time due to a clock source is zero because the device uses the same clock configuration in Run mode; thus, there is no latency involved with respect to the clocks.

Table 32-27. Wake from Sleep Characteristics

| Parameter No | Parameter | Parameter Name | Min | Nom | Max | Unit |
|--------------|----------------|--|-----|-----|------------------|---------------|
| D1 | T_{PIOSC} | Time to restore PIOSC as System Clock in Sleep mode | - | - | N/A ^a | μs |
| D2 | T_{MOSC} | Time to restore MOSC as System Clock in Sleep mode | - | - | N/A ^b | μs |
| D3 | T_{PLL} | Time to restore PLL as System Clock in Sleep mode | - | - | N/A ^c | μs |
| D4 | T_{LDO} | Time to restore LDO to 1.2 V in Sleep mode | - | - | 39 | μs |
| D5 | T_{FLASH} | Time to restore Flash to active state from low power state in Sleep mode | - | - | 5 | μs |
| D6 | $T_{SRAML P}$ | Time to restore SRAM to active state from low power state in Sleep mode | - | - | 15 | μs |
| D7 | $T_{SRAMSTBY}$ | Time to restore SRAM to active state from standby state in Sleep mode | - | - | 15 | μs |

a. Because the PIOSC is enabled in both Run and Sleep Mode for this configuration, no restoration time is required.

b. Because the MOSC is enabled in both Run and Sleep Mode for this configuration, no restoration time is required.

c. Because the PLL is enabled in both Run and Sleep Mode for this configuration, no restoration time is required.

Table 32-28. Wake from Deep Sleep Characteristics

| Parameter No | Parameter | Parameter Name | Min | Nom | Max | Unit |
|--------------|-----------------|--|-----|-----|--|--------------------------------------|
| D8 | $T_{PIOSCDS}$ | Time to restore PIOSC as System Clock in Deep Sleep Mode | - | - | 14 | Deep Sleep Clock Cycles ^a |
| D9 | T_{MOSCDS} | Time to restore MOSC as System Clock in Deep Sleep Mode | - | - | 18 | ms |
| D10 | T_{PLLDS} | Time to restore PLL as System Clock in Deep Sleep Mode | - | - | 1 cycle of Deep Sleep Clock + 512 cycles of PLL reference Clock ^a | clocks |
| D11 | T_{LDODS} | Time to restore LDO to 1.2 V in Deep Sleep Mode | - | - | 39 | μs |
| D12 | $T_{FLASHLPDS}$ | Time to restore Flash to active state from low power state | - | - | 5 | μs |
| D13 | $T_{SRAML PDS}$ | Time to restore SRAM to active state from low power state | - | - | 15 | μs |

Table 32-28. Wake from Deep Sleep Characteristics (continued)

| Parameter No | Parameter | Parameter Name | Min | Nom | Max | Unit |
|--------------|-------------------------|---|-----|-----|-----|------|
| D14 | T _{SRAMSTBYDS} | Time to restore SRAM to active state from standby state | - | - | 15 | μs |

a. Deep Sleep Clock can vary. See page 293 for the Deep Sleep Clock options.

32.11 Hibernation Module

The Hibernation module requires special system implementation considerations because it is intended to power down all other sections of its host device, refer to “Hibernation Module” on page 563.

Table 32-29. Hibernation Module Battery Characteristics

| Parameter | Parameter Name | Min | Nominal | Max | Unit |
|----------------------------------|---|-----|---------|------------------|------|
| V _{BAT} | Battery supply voltage | 1.8 | 3.0 | 3.6 ^a | V |
| V _{BATRMP} ^b | V _{BAT} battery supply voltage ramp time | 0 | - | 0.7 | V/μs |
| V _{LOWBAT} | Low battery detect voltage, VBATSEL=0x0 | 1.8 | 1.9 | 2.0 | V |
| | Low battery detect voltage, VBATSEL=0x1 | 2.0 | 2.1 | 2.2 | V |
| | Low battery detect voltage, VBATSEL=0x2 | 2.2 | 2.3 | 2.4 | V |
| | Low battery detect voltage, VBATSEL=0x3 | 2.4 | 2.5 | 2.6 | V |

a. To ensure proper functionality, any voltage input higher than V_{BAT} Max, must be connected through a diode.

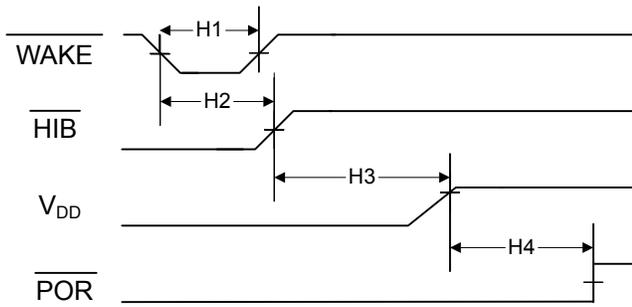

b. For recommended V_{BAT} RC circuit values, refer to the diagrams located in “Hibernation Clock Source” on page 567.

Table 32-30. Hibernation Module Characteristics

| Parameter No | Parameter | Parameter Name | Min | Nom | Max | Unit |
|--------------|--------------------------|--|-----|--|-----|--------------------------|
| H1 | T _{WAKE} | \overline{WAKE} assertion time | 100 | - | - | ns |
| H2 | T _{WAKE_TO_HIB} | \overline{WAKE} assert to \overline{HIB} desassert (wake up time) | - | - | 1 | Hibernation clock period |
| H3 | T _{VDD_RAMP} | V _{DD} ramp to 3.0 V | - | Depends on characteristics of power supply | - | μs |
| H4 | T _{VDD_CODE} | V _{DD} at 3.0 V to internal POR deassert; first instruction executes | - | - | 500 | μs |
| H5 | DC _{RTCCLK} | Duty cycle for RTCCLK output signal, when using a 32.768-kHz crystal | 40 | - | 60 | % |
| | | Duty cycle for RTCCLK output signal, when using a 32.768-kHz external single-ended (bypass) clock source | 30 | - | 70 | % |

Table 32-31. Hibernation Module Tamper I/O Characteristics

| Parameter | Parameter Name | Min | Nominal | Max | Unit |
|-------------------|---|-----------------------|---------|----------|------|
| R _{TPU} | TMPR _n pull-up resistor | 3.5 - | 4.4 | 5.2 - | MΩ |
| T _{SP} | TMPR _n pulse width with short glitch filter | 62 | - | - | μs |
| T _{LP} | TMPR _n pulse width with long glitch filter | 94 | - | - | ms |
| T _{NMIS} | TMPR _n assertion to NMI (short glitch filter) | - | - | 95 | μs |
| T _{NMIL} | TMPR _n assertion to NMI (long glitch filter) | - | - | 94 | ms |
| V _{IH} | TMPR _n high-level input voltage when operating from V _{BAT} | V _{BAT} *0.8 | - | - | V |

Figure 32-15. Hibernation Module Timing

32.12 Flash Memory

Table 32-32. Flash Memory Characteristics

| Parameter | Parameter Name | Min | Nom | Max | Unit |
|----------------------|---|---------|-----|------|--------|
| PE _{CYC} | Number of program/erase cycles ^a | 100,000 | - | - | cycles |
| T _{RET} | Data retention with 100% power-on hours at T _J =85°C | 20 | - | - | years |
| T _{RET_EXT} | Data retention with 10% power-on hours at T _J =125°C and 90% power-on hours at T _J =100°C | 11 | - | - | years |
| T _{PROG64} | Program time for double-word-aligned (64 bits) data ^b | 30 | 100 | 300 | μs |
| T _{ERASE} | Page erase time, <1k cycles | - | 8 | 15 | ms |
| | Page erase time, 10k cycles | - | 15 | 40 | ms |
| | Page erase time, 100k cycles | - | 75 | 500 | ms |
| T _{ME} | Mass erase time, <1k cycles | - | 10 | 25 | ms |
| | Mass erase time, 10k cycles | - | 20 | 70 | ms |
| | Mass erase time, 100k cycles | - | 300 | 2500 | ms |

a. A program/erase cycle is defined as switching the bits from 1-> 0 -> 1.

b. If programming fewer than 64 bits of data, the programming time is the same. For example, if only 32 bits of data need to be programmed, the other 32 bits are masked off.

32.13 EEPROM

Table 32-33. EEPROM Characteristics^a

| Parameter | Parameter Name | Min | Nom | Max | Unit |
|---------------------------------|---|---------|---------------|-----------|---------------|
| EPE _{CYC} ^b | Number of mass program/erase cycles of a single word ^c | 500,000 | - | - | cycles |
| ET _{RET} | Data retention with 100% power-on hours at T _J =85°C | 20 | - | - | years |
| ET _{RET_EXTEMP} | Data retention with 10% power-on hours at T _J =125°C and 90% power-on hours at T _J =100°C | 11 | - | - | years |
| ET _{PROG} | Program time for 32 bits of data with memory space available | - | 110 | 600 | µs |
| | Program time for 32 bits of data in which a copy to the copy buffer is required, the copy buffer has space and less than 10% of EEPROM endurance used | - | 30 | - | ms |
| | Program time for 32 bits of data in which a copy to the copy buffer is required, the copy buffer has space and greater than 90% of EEPROM endurance used | - | - | 900 | ms |
| | Program time for 32 bits of data in which a copy of the copy buffer is required, the copy buffer requires an erase and less than 10% of EEPROM endurance used | - | 60 | - | ms |
| | Program time for 32 bits of data a copy to the copy buffer is required, the copy buffer requires an erase and greater than 90% of EEPROM endurance used | - | - | 1800 | ms |
| ET _{READ} | Read access time ^d | - | 7+ 2*(EWS) | 9+4*(EWS) | system clocks |
| ET _{ME} | Mass erase time, <1k cycles | - | 8 | 15 | ms |
| | Mass erase time, 10k cycles | - | 15 | 40 | ms |
| | Mass erase time, 100k cycles | - | 75 | 500 | ms |

- a. Because the EEPROM operates as a background task and does not prevent the CPU from executing from Flash memory, the operation will complete within the maximum time specified provided the EEPROM operation is not stalled by a Flash memory program or erase operation.
- b. One word can be written more than 500K times, but these writes impact the endurance of the words in the meta-block that the word is within. Different words can be written such that any or all words can be written more than 500K times when write counts per word stay about the same. See the section called "Endurance" on page 651 for more information.
- c. A program/erase cycle is defined as switching the bits from 1-> 0 -> 1.
- d. The EWS field is programmed in the **MEMTIM0** register at Sysctl Offset 0x0C0.

32.14 Input/Output Pin Characteristics

Note: All GPIO signals are 3.3-V tolerant, except for PB1 (USB0VBUS) which is 5-V tolerant. See “Signal Description” on page 773 for more information on GPIO configuration.

Two types of pads are provided on the device:

- Fast GPIO pads: These pads provide variable, programmable drive strength and optimized voltage output levels.
- Slow GPIO pads: These pads provide 2-mA drive strength and are designed to be sensitive to voltage inputs. The following GPIOs port pins are designed with Slow GPIO Pads:
 - PJ1

Note: Port pins $PL6$ and $PL7$ operate as Fast GPIO pads, but have 4-mA drive capability only. GPIO register controls for drive strength, slew rate and open drain have no effect on these pins. The registers which have no effect are as follows: **GPIODR2R**, **GPIODR4R**, **GPIODR8R**, **GPIODR12R**, **GPIOSLR**, and **GPIODR**.

Note: Port pins $PM[7:4]$ operate as Fast GPIO pads but support only 2-, 4-, 6-, and 8-mA drive capability. 10- and 12-mA drive are not supported. All standard GPIO register controls, except for the **GPIODR12R** register, apply to these port pins.

Table 32-34. Fast GPIO Module Characteristics^{abcd}

| Parameter | Parameter Name | Min | Nom | Max | Unit |
|-----------------|---|------|------|-------|------------|
| C_{LGPIO} | Capacitive loading for measurements given in this table ^e | - | - | 50 | pF |
| R_{GPIOU} | Fast GPIO internal pull-up resistor ^f | 12.1 | 16.0 | 20.2 | k Ω |
| $R_{GPIOU4MA}$ | Fast GPIO $PL6$ and $PL7$ (4-mA only) pull-up resistor | 25 | - | 40 | k Ω |
| R_{GPIOPD} | Fast GPIO internal pull-down resistor ^f | 13.0 | 20.5 | 35.5 | k Ω |
| $R_{GPIOPD4MA}$ | Fast GPIO $PL6$ and $PL7$ (4-mA only) pull-down resistor | 10 | 14.3 | 17 | k Ω |
| I_{LKG+} | Fast GPIO input leakage current, $0V \leq V_{IN} \leq V_{DD}$ GPIO pins ^g | - | - | 400 | nA |
| | Fast GPIO input leakage current, $0V < V_{IN} \leq V_{DD}$, Fast GPIO pins configured as ADC or analog comparator inputs | - | - | 400 | nA |
| I_{INJ-} | DC injection current, $V_{IN} \leq 0V$ | - | - | 60 | μ A |
| $I_{MAXINJ-}$ | Max negative injection if not voltage protected ^d | - | - | -0.5 | mA |
| T_{GPIOR} | Fast GPIO rise time, 2-mA drive ^h | - | 7.85 | 11.73 | ns |
| | Fast GPIO rise time, 4-mA drive ^h | | 4.15 | 6.35 | ns |
| | Fast GPIO rise time, 8-mA drive ^h | | 2.33 | 3.73 | ns |
| | Fast GPIO rise time, 8-mA drive with slew rate control ^h | | 3.77 | 5.76 | ns |
| | Fast GPIO rise time, 10-mA drive ^h | | 1.98 | 3.22 | ns |
| | Fast GPIO rise time, 12-mA drive ^h | | 1.75 | 2.9 | ns |

Table 32-34. Fast GPIO Module Characteristics (continued)

| Parameter | Parameter Name | Min | Nom | Max | Unit |
|--------------------|---|-----|------|------|------|
| T _{GPIOF} | Fast GPIO fall time, 2-mA drive ⁱ | - | 10.3 | 16.5 | ns |
| | Fast GPIO fall time, 4-mA drive ⁱ | | 5.15 | 8.29 | ns |
| | Fast GPIO fall time, 8-mA drive ⁱ | | 2.58 | 4.16 | ns |
| | Fast GPIO fall time, 8-mA drive with slew rate control ⁱ | | 3.54 | 5.55 | ns |
| | Fast GPIO fall time, 10-mA drive ⁱ | | 2.07 | 3.34 | ns |
| | Fast GPIO fall time, 12-mA drive ⁱ | | 1.73 | 2.78 | ns |

- a. V_{DD} must be within the range specified in Table 32-6 on page 2097.
- b. Leakage and Injection current characteristics specified in this table also apply to XOSC0 and XOSC1 inputs.
- c. Note that for the ADC's external reference inputs, care must be taken to avoid a current limiting resistor (refer to I_{VREF} spec in Table 32-44 on page 2138)
- d. I/O pads should be protected if at any point the IO voltage has a possibility of going outside the limits shown in the table. If the part is unpowered, the IO pad Voltage or Current must be limited (as shown in this table) to avoid powering the part through the IO pad, causing potential irreversible damage.
- e. Refer to individual peripheral sections for specific loading information.
- f. This value includes all GPIO except for port pins PL6 and PL7.
- g. The leakage current is measured with V_{IN} applied to the corresponding pin(s). The leakage of digital port pins is measured individually. The port pin is configured as an input and the pull-up/pull-down resistor is disabled.
- h. Time measured from 20% to 80% of V_{DD}.
- i. Time measured from 80% to 20% of V_{DD}.

Table 32-35. Slow GPIO Module Characteristics^{abc}

| Parameter | Parameter Name | Min | Nom | Max | Unit |
|---------------------|--|------|------|------|------|
| C _{LGPIO} | Capacitive loading for measurements given in this table ^d | - | - | 50 | pF |
| R _{GPIOPU} | Slow GPIO internal pull-up resistor | 13.8 | 20.0 | 31.4 | kΩ |
| R _{GPIOPD} | Slow GPIO internal pull-down resistor | 13.0 | 20.5 | 35.5 | kΩ |
| I _{LKG+} | Slow GPIO input leakage current, 0 V ≤ V _{IN} ≤ V _{DD} , GPIO pins ^e | - | - | 3.25 | nA |
| | Slow GPIO input leakage current, 0 V < V _{IN} ≤ V _{DD} , GPIO pins configured as ADC or analog comparator inputs | - | - | 3.25 | nA |
| I _{INJ-} | DC injection current, V _{IN} ≤ 0 V | - | - | 3.42 | μA |
| T _{GPIOR} | Slow GPIO rise time, 2-mA drive ^f | - | 19.3 | 29.8 | ns |
| T _{GPIOF} | Slow GPIO fall time, 2-mA drive ^g | - | 12.8 | 21.1 | ns |

- a. V_{DD} must be within the range specified in Table 32-6 on page 2097.
- b. V_{IN} must be within the range specified in Table 32-1 on page 2095. Leakage current outside of this maximum voltage is not guaranteed and can result in permanent damage of the device.
- c. To avoid potential damage to the part, either the voltage or current on the non-Power, non-WAKE input/outputs should be limited externally as shown in this table.
- d. Refer to individual peripheral sections for specific loading information.
- e. The leakage current is measured with V_{IN} applied to the corresponding pin(s). The leakage of digital port pins is measured individually. The port pin is configured as an input and the pull-up/pull-down resistor is disabled.
- f. Time measured from 20% to 80% of V_{DD}.
- g. Time measured from 80% to 20% of V_{DD}.

32.14.1 Types of I/O Pins and ESD Protection

Caution – All device I/Os pins, except for PB1, are NOT 5V tolerant; voltages in excess of the limits shown in Table 32-6 on page 2097 can permanently damage the device. PB1 is used for the USB's USB0VBUS signal, which requires a 5-V input.

32.14.1.1 Hibernate $\overline{\text{WAKE}}$ pin

The Hibernate $\overline{\text{WAKE}}$ pin uses ESD protection, similar to the one shown in Figure 32-16 on page 2128. This ESD protection prevents a direct path between this pad and any power supply rails in the device. The $\overline{\text{WAKE}}$ pad input voltage should be kept inside the maximum ratings specified in Table 32-1 on page 2095 to ensure current leakage and current injections are within acceptable range. Current leakages and current injection for these pins are specified in Table 32-36 on page 2128.

Figure 32-16. ESD Protection

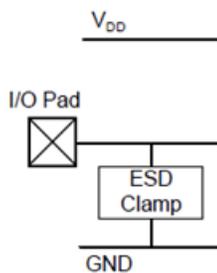

Table 32-36. Pad Voltage/Current Characteristics for Hibernate $\overline{\text{WAKE}}$ Pin^{ab}

| Parameter | Parameter Name | Min | Nom | Max | Unit |
|-------------------|--|-----|-----|------|---------------|
| $I_{\text{LKG}+}$ | Positive IO leakage for $V_{\text{DD}} \leq V_{\text{IN}} \leq V_{\text{BAT}} + 0.3\text{V}$ | - | - | 300 | nA |
| $I_{\text{LKG}-}$ | Negative IO leakage for $-0.3\text{V} \leq V_{\text{IN}} \leq 0\text{V}^{\text{c}}$ | - | - | 43.3 | μA |
| $I_{\text{INJ}+}$ | Max positive injection if not voltage protected ^d | - | - | 2 | mA |
| $I_{\text{INJ}-}$ | Max negative injection if not voltage protected ^d | - | - | -0.5 | mA |

a. V_{IN} must be within the range specified in Table 32-1 on page 2095. Leakage current outside of this maximum voltage is not guaranteed and can result in permanent damage of the device.

b. V_{DD} must be within the range specified in Table 32-6 on page 2097.

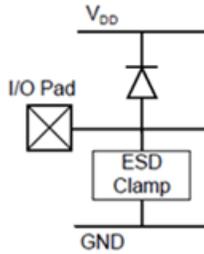

c. Leakage outside the minimum range (-0.3V) is unbounded and must be limited to $I_{\text{INJ}-}$ using an external resistor.

d. If the I/O pad is not voltage limited, it should be current limited (to $I_{\text{INJ}+}$ and $I_{\text{INJ}-}$) if there is any possibility of the pad voltage exceeding the V_{IO} limits (including transient behavior during supply ramp up, or at any time when the part is unpowered).

32.14.1.2 Non-Power I/O Pins

Most non-power I/Os (with the exception of the I/O pad for Hibernate $\overline{\text{WAKE}}$ input) have ESD protection as shown in Figure 32-17 on page 2129.

These I/Os have an ESD clamp to ground and a diode connection to the corresponding power supply rail. The voltage and current of these I/Os should follow the specifications in Table 32-37 on page 2129 to prevent potential damage to the device. In addition, it is recommended that the ADC external reference specifications in Table 32-44 on page 2138 be adhered to prevent any gain error.

Figure 32-17. ESD Protection for Non-Power Pins (Except $\overline{\text{WAKE}}$ Signal)Table 32-37. Non-Power I/O Pad Voltage/Current Characteristics^{abc}

| Parameter | Parameter Name | Min | Nom | Max | Unit |
|------------|--|------|----------|--------------|---------------|
| V_{IO}^d | IO pad voltage limits if voltage protected | -0.3 | V_{DD} | $V_{DD}+0.3$ | V |
| I_{LKG+} | Positive IO leakage for $V_{DD} \leq V_{IN} \leq V_{IO} \text{ MAX}^e$ | - | - | 400 | nA |
| I_{LKG-} | Negative IO leakage for $V_{IO} \text{ MIN} \leq V_{IN} \leq 0V^e$ | - | - | 60 | μA |
| I_{INJ+} | Max positive injection if not voltage protected ^f | - | - | 2 | mA |
| I_{INJ-} | Max negative injection if not voltage protected ^f | - | - | -0.5 | mA |

- To avoid potential damage to the part, either the voltage or current on the non-Power, non- $\overline{\text{WAKE}}$ input/outputs should be limited externally as shown in this table.
- Note that for the ADC's external reference inputs, care must be taken to avoid a current limiting resistor (refer to IVREF spec in Table 32-44 on page 2138)
- I/O pads should be protected if at any point the IO voltage has a possibility of going outside the limits shown in the table. If the part is unpowered, the IO pad Voltage or Current must be limited (as shown in this table) to avoid powering the part through the IO pad, causing potential irreversible damage.
- The Hibernate $\overline{\text{XOSC}}$ pins are non-failsafe and should follow the limits for V_{IO} with respect to both V_{DD} and V_{BAT} . Thus V_{IO} for the HIB $\overline{\text{XOSC}}$ pins should also fall within a MIN of -0.3 and a MAX of $V_{BAT} + 0.3$.
- MIN and MAX leakage current for the case when the I/O is voltage protected to $V_{IO} \text{ Min}$ or $V_{IO} \text{ Max}$.
- If the I/O pad is not voltage limited, it should be current limited (to I_{INJ+} and I_{INJ-}) if there is any possibility of the pad voltage exceeding the V_{IO} limits (including transient behavior during supply ramp up, or at any time when the part is unpowered).

32.15 External Peripheral Interface (EPI)

Table 32-38. EPI Interface Load Conditions

| Signals | Load Value (C_L) |
|---------------------------------------|----------------------|
| EPIOS[35:0] SDRAM interface | 30 pF |
| EPIOS[35:0] General-Purpose interface | |
| EPIOS[35:0] Host-Bus interface | |
| EPIOS[35:0] PSRAM interface | 40 pF |

When the EPI module is in SDRAM mode, EPI CLK must be configured to 12 mA. The EPI data bus can be configured to 8 mA. Table 32-39 on page 2130 shows the rise and fall times in SDRAM mode. When the EPI module is in Host-Bus or General-Purpose mode, the values in “Input/Output Pin Characteristics” on page 2126 should be used.

Table 32-39. EPI SDRAM Characteristics

| Parameter | Parameter Name | Condition | Min | Nom | Max | Unit |
|--------------|--|----------------------------|-----|-----|-----|------|
| T_{SDRAMR} | EPI Rise Time (from 20% to 80% of V_{DD}) | 12-mA drive, $C_L = 30$ pF | - | 2 | 3 | ns |
| T_{SDRAMF} | EPI Fall Time (from 80% to 20% of V_{DD}) | 12-mA drive, $C_L = 30$ pF | - | 2 | 3 | ns |

Table 32-40. EPI SDRAM Interface Characteristics^a

| Parameter No | Parameter | Parameter Name | Min | Nom | Max | Unit |
|--------------|-----------|------------------------|-------|-----|-----|---------|
| E1 | T_{CK} | SDRAM Clock period | 16.67 | - | - | ns |
| E2 | T_{CH} | SDRAM Clock high time | 8.33 | - | - | ns |
| E3 | T_{CL} | SDRAM Clock low time | 8.33 | - | - | ns |
| E4 | T_{COV} | CLK to output valid | - | - | 4 | ns |
| E5 | T_{COI} | CLK to output invalid | - | - | 4 | ns |
| E6 | T_{COT} | CLK to output tristate | - | - | 4 | ns |
| E7 | T_S | Input set up to CLK | 8.5 | - | - | ns |
| E8 | T_H | CLK to input hold | 0 | - | - | ns |
| E9 | T_{PU} | Power-up time | 100 | - | - | μ s |
| E10 | T_{RP} | Precharge all banks | 20 | - | - | ns |
| E11 | T_{RFC} | Auto refresh | 66 | - | - | ns |
| E12 | T_{MRD} | Program mode register | 2 | - | - | EPI CLK |

a. The EPI SDRAM interface must use 12-mA drive.

| TEMPERATURE SENSOR | | | | | |
| V_{TSENS} | Temperature sensor voltage, junction temperature 25 °C | - | 1.633 | - | V |
| S_{TSENS} | Temperature sensor slope at: -40°C to 85 °C ambient (industrial temperature part) -40°C to 105 °C ambient (extended temperature part) | - | -13.3 | - | mV/°C |
| E_{TSENS} | Temperature sensor accuracy at: ^z -40°C to 85 °C ambient (industrial temperature part) -40°C to 105 °C ambient (extended temperature part) | - | - | ±5 | °C |

a. Values are at $V_{REF+} = 3.3V$, $F_{ADC} = 16$ MHz unless otherwise noted.

b. Best design practices suggest that static or quiet digital I/O signals be configured adjacent to sensitive analog inputs to reduce capacitive coupling and cross talk. Unexpected results can occur if a switching digital I/O is placed adjacent to an ADC input channel or voltage reference input. In addition, analog signals configured adjacent to ADC input channels or reference inputs must meet the R_{ADC} equivalent input resistance given in this table and must be band-limited to 100 kHz or lower.

c. Two capacitors in parallel. Note that these capacitors should be as close to the die as possible.

d. Assumes external filtering network between VREFA+ and VREFA- as shown in Figure 32-28 on page 2143. External reference noise level must be under 12bit (-74 dB) of Full Scale input, over input bandwidth, measured at VREFA+ - VREFA-.

e. Internal reference is connected directly between V_{DDA} and GNDA ($V_{REFi} = V_{DDA} - GNDA$). In this mode, E_O , E_G , E_T , and dynamic specifications are adversely affected due to internal voltage drop and noise on V_{DDA} and GNDA. Internal reference voltage is selected when V_{REF} field in the **ADCCTL** register is 0x0.

- f. $V_{ADCIN} = V_{INP} - V_{INN}$
- g. With signal common mode as $V_{DDA}/2$.
- h. With signal common mode as $(V_{REF+} + V_{REF-})/2$.
- i. This parameter is defined as the average of the differential inputs.
- j. As shown in Figure 32-29 on page 2143, R_{ADC} is the total equivalent resistance in the input line all the way up to the sampling node at the input of the ADC.
- k. See "System Clock Specification with ADC Operation" on page 2119 for full ADC clock frequency specification.
- l. ADC conversion time (T_c) includes the ADC sample time (T_s).
- m. Low noise environment is assumed in order to obtain values close to spec. Board must have good ground isolation between analog and digital grounds, a clean reference voltage is assumed, and input signal must be bandlimited to Nyquist bandwidth. No anti-aliasing filter is provided internally.
- n. ADC static measurements taken by averaging over several samples. At least 20-sample averaging is assumed to obtain expected typical or maximum spec values.
- o. 12-bit DNL
- p. Gain error is measured at max code after compensating for offset. Gain error is equivalent to "Full Scale Error." It can be given in % of slope error, or in LSB, as done here.
- q. Total Unadjusted Error is the maximum error at any one code versus the ideal ADC curve. It includes all other errors (offset error, gain error and INL) at any given ADC code.
- r. A low noise environment is assumed in order to obtain values close to spec. The board must have good ground isolation between analog and digital grounds and a clean reference voltage. The input signal must be band-limited to Nyquist bandwidth. No anti-aliasing filter is provided internally.
- s. ADC dynamic characteristics are measured using low-noise board design, with low-noise reference voltage (< -74 dB noise level in signal BW) and low-noise analog supply voltage. Board noise and ground bouncing couple into the ADC and affect dynamic characteristics. Clean external reference must be used to achieve shown specs.
- t. Differential signal with correct common mode, applied between two ADC inputs.
- u. SDR = -THD in dB.
- v. For higher frequency inputs, degradation in SDR should be expected.
- w. SNDR = $S/(N+D)$ = SINAD (in dB)
- x. Effective number of bits (ENOB) can be calculated from SNDR: $ENOB = (SNDR - 1.76) / 6.02$.
- y. Single ended inputs are more sensitive to board and trace noise than differential inputs; SNR and SNDR measurements on single-ended inputs are highly dependent on how clean the test set-up is. If the input signal is not well-isolated on the board, higher noise than specified could potentially be seen at the ADC output.
- z. Note that this parameter does not include ADC error.

Table 32-45. ADC Electrical Characteristics for ADC at 2 Msps^{ab}

| Parameter | Parameter Name | Min | Nom | Max | Unit |
|----------------------------------|---|-------|--------------------------|-----------|---------|

| SDR_D | Signal-to-distortion ratio, Differential input, V_{ADCIN} : -3dB FS, 1KHz ^{uv} | 70 | 75 | - | dB |

Table 32-45. ADC Electrical Characteristics for ADC at 2 Msps (continued)

| Parameter | Parameter Name | Min | Nom | Max | Unit |
|-------------------|---|-----|-----|-----|------|
| SNDR _D | Signal-to-Noise+Distortion ratio, Differential input, V _{ADCIN} : -3dB FS, 1KHz ^{twx} | 65 | 70 | - | dB |
| SNR _S | Signal-to-noise-ratio, Single-ended input, V _{ADCIN} : -20dB FS, 1KHz ^y | 58 | 65 | - | dB |
| SDR _S | Signal-to-distortion ratio, Single-ended input, V _{ADCIN} : -3dB FS, 1KHz ^{uv} | 68 | 72 | - | dB |
| SNDR _S | Signal-to-Noise+Distortion ratio, Single-ended input, V _{ADCIN} : -3dB FS, 1KHz ^{ywx} | 58 | 63 | - | dB |

- a. Values are at V_{REF+} = 3.3V, F_{ADC} = 32 MHz unless otherwise noted.
- b. Best design practices suggest that static or quiet digital I/O signals be configured adjacent to sensitive analog inputs to reduce capacitive coupling and cross talk. Unexpected results can occur if a switching digital I/O is placed adjacent to an ADC input channel or voltage reference input. In addition, analog signals configured adjacent to ADC input channels or reference inputs must meet the R_{ADC} equivalent input resistance given in this table and must be band-limited to 100 kHz or lower.
- c. Two capacitors in parallel. Note that these capacitors should be as close to the die as possible.
- d. Assumes external filtering network between VREFA+ and VREFA- as shown in Figure 32-28 on page 2143. External reference noise level must be under 12bit (-74 dB) of Full Scale input, over input bandwidth, measured at VREFA+ - VREFA-.
- e. Internal reference is connected directly between V_{DDA} and GNDA (VREFi = V_{DDA} - GNDA). In this mode, E_O, E_G, E_T, and dynamic specifications are adversely affected due to internal voltage drop and noise on V_{DDA} and GNDA. Internal reference voltage is selected when VREF field in the **ADCCTL** register is 0x0.
- f. V_{ADCIN} = V_{INP} - V_{INN}
- g. With signal common mode as V_{DDA}/2.
- h. With signal common mode as (V_{REF+} + V_{REF-})/2.
- i. This parameter is defined as the average of the differential inputs.
- j. As shown in Figure 32-29 on page 2143, R_{ADC} is the total equivalent resistance in the input line all the way up to the sampling node at the input of the ADC.
- k. See "System Clock Specification with ADC Operation" on page 2119 for full ADC clock frequency specification.
- l. ADC conversion time (T_c) includes the ADC sample time (T_s).
- m. Low noise environment is assumed in order to obtain values close to spec. Board must have good ground isolation between analog and digital grounds, a clean reference voltage is assumed, and input signal must be bandlimited to Nyquist bandwidth. No anti-aliasing filter is provided internally.
- n. ADC static measurements taken by averaging over several samples. At least 20-sample averaging is assumed to obtain expected typical or maximum spec values.
- o. 12-bit DNL
- p. Gain error is measured at max code after compensating for offset. Gain error is equivalent to "Full Scale Error." It can be given in % of slope error, or in LSB, as done here.
- q. Total Unadjusted Error is the maximum error at any one code versus the ideal ADC curve. It includes all other errors (offset error, gain error and INL) at any given ADC code.
- r. A low noise environment is assumed in order to obtain values close to spec. The board must have good ground isolation between analog and digital grounds and a clean reference voltage. The input signal must be band-limited to Nyquist bandwidth. No anti-aliasing filter is provided internally.
- s. ADC dynamic characteristics are measured using low-noise board design, with low-noise reference voltage (< -74dB noise level in signal BW) and low-noise analog supply voltage. Board noise and ground bouncing couple into the ADC and affect dynamic characteristics. Clean external reference must be used to achieve shown specs.
- t. Differential signal with correct common mode, applied between two ADC inputs.
- u. SDR = -THD in dB.
- v. For higher frequency inputs, degradation in SDR should be expected.
- w. SNDR = S/(N+D) = SINAD (in dB)
- x. Effective number of bits (ENOB) can be calculated from SNDR: ENOB = (SNDR - 1.76) / 6.02.

y. Single ended inputs are more sensitive to board and trace noise than differential inputs; SNR and SNDR measurements on single-ended inputs are highly dependent on how clean the test set-up is. If the input signal is not well-isolated on the board, higher noise than specified could potentially be seen at the ADC output.

32.17 Synchronous Serial Interface (SSI)

Table 32-46. SSI Characteristics

| Parameter No. | Parameter | Parameter Name | Min | Nom | Max | Unit |
|---------------|-----------------------|---|--------------------|-----|--------------------|------|
| S1 | T _{CLK_PER} | SSIClk cycle time, as master ^a | 16.67 | - | - | ns |
| | | SSIClk cycle time, as slave ^b | 100 | - | - | ns |
| S2 | T _{CLK_HIGH} | SSIClk high time, as master | 8.33 | - | - | ns |
| | | SSIClk high time, as slave | 50 | - | - | ns |
| S3 | T _{CLK_LOW} | SSIClk low time, as master | 8.33 | - | - | ns |
| | | SSIClk low time, as slave | 50 | - | - | ns |
| S4 | T _{CLKR} | SSIClk rise time ^c | 1.25 | - | - | ns |
| S5 | T _{CLKF} | SSIClk fall time ^c | 1.25 | - | - | ns |
| S6 | T _{TXDMOV} | Master Mode: Master Tx Data Output (to slave) Valid Time from edge of SSIClk | - | - | 4.00 | ns |
| S7 | T _{TXDMOH} | Master Mode: Master Tx Data Output (to slave) Hold Time after next SSIClk | 0.60 | - | - | ns |
| S8 | T _{RXDMS} | Master Mode: Master Rx Data In (from slave) setup time | 7.89 | - | - | ns |
| S9 | T _{RXDMH} | Master Mode: Master Rx Data In (from slave) hold time | 0 | - | - | ns |
| S10 | T _{TXDSOV} | Slave Mode: Master Tx Data Output (to Master) Valid Time from edge of SSIClk | - | - | 47.60 ^d | ns |
| S11 | T _{TXDSOH} | Slave Mode: Slave Tx Data Output (to Master) Hold Time from next SSIClk | 37.4 ^e | - | - | ns |
| S13 | T _{RXDSSU} | Slave Mode: Rx Data In (from master) setup time | 0 | - | - | ns |
| S14 | T _{RXDSSH} | Slave Mode: Rx Data In (from master) hold time | 37.03 ^f | - | - | ns |

a. In master mode, the system clock must be at least twice as fast as the SSIClk.

b. In slave mode, the system clock must be at least 12 times faster than the SSIClk.

c. Note that the delays shown are using 12-mA drive strength.

d. This MAX value is for the minimum slave mode T_{SYSClk} period (8.33 ns). To find the MAX T_{TXDSOV} value for a larger T_{SYSClk}, use the equation: 4*T_{SYSClk}+14.25.

e. This MIN value is for the minimum slave mode T_{SYSClk} (8.33 ns). To find the MIN T_{TXDSOH} value for a larger T_{SYSClk}, use the equation: 4*T_{SYSClk}+4.08.

f. This MIN value is for the minimum slave mode T_{SYSClk} (8.33 ns). To find the MIN T_{TXDSSH} value for a larger T_{SYSClk}, use the equation: 4*T_{SYSClk}+3.70.

| S21 | T _{TXDMOH} | Master Mode: Master SSInXDATn Data Output (to slave) Hold Time after next SSIClk | 0.60 | - | - | ns |
| S22 | T _{RXDMS} | Master Mode: Master SSInXDATn Data In (from slave) setup time | 5.78 | - | - | ns |
| S23 | T _{RXDMH} | Master Mode: Master SSInXDATn Data In (from slave) hold time | 0 | - | - | ns |

a. Parameters S15 through S23 correspond to parameters S1 through S9 in Figure 32-30 and Figure 32-31.

b. In master mode, the system clock must be at least twice as fast as the SSIClk.

c. Note that the delays shown are using 12-mA drive strength.

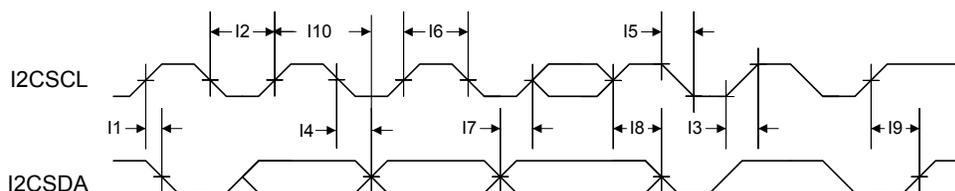

32.18 Inter-Integrated Circuit (I²C) Interface

Table 32-48. I²C Characteristics

| Parameter No. | Parameter | Parameter Name | Min | Nom | Max | Unit |
|-----------------|-------------------|---|-----|---------------------|--------------|---------------|
| I1 ^a | T _{SCH} | Start condition hold time | 36 | - | - | system clocks |
| I2 ^a | T _{LP} | Clock Low period | 36 | - | - | system clocks |
| I3 ^b | T _{SRT} | I ² C _{SCL} /I ² C _{SDA} rise time (V _{IL} = 0.5 V to V _{IH} = 2.4 V) | - | - | (see note b) | ns |
| I4 | T _{DH} | Data hold time (slave) | - | 2 | - | system clocks |
| | | Data hold time (master) | - | 7 | - | system clocks |
| I5 ^c | T _{SFT} | I ² C _{SCL} /I ² C _{SDA} fall time (V _{IH} = 2.4 V to V _{IL} = 0.5 V) | - | 9 | 10 | ns |
| I6 ^a | T _{HT} | Clock High time | 24 | - | - | system clocks |
| I7 | T _{DS} | Data setup time | 18 | - | - | system clocks |
| I8 ^a | T _{SCSR} | Start condition setup time (for repeated start condition only) | 36 | - | - | system clocks |
| I9 ^a | T _{SCS} | Stop condition setup time | 24 | - | - | system clocks |
| I10 | T _{DV} | Data Valid (slave) | - | 2 | - | system clocks |
| | | Data Valid (master) | - | (6 * (1 + TPR)) + 1 | - | system clocks |

- a. Values depend on the value programmed into the TPR bit in the I²C Master Timer Period (I2CMTPR) register; a TPR programmed for the maximum I²C_{SCL} frequency (TPR=0x2) results in a minimum output timing as shown in the table above. The I²C interface is designed to scale the actual data transition time to move it to the middle of the I²C_{SCL} Low period. The actual position is affected by the value programmed into the TPR; however, the numbers given in the above values are minimum values.
- b. Because I²C_{SCL} and I²C_{SDA} operate as open-drain-type signals, which the controller can only actively drive low, the time I²C_{SCL} or I²C_{SDA} takes to reach a high level depends on external signal capacitance and pull-up resistor values.
- c. Specified at a nominal 50 pF load.

Figure 32-33. I²C Timing

32.19 Ethernet Controller

32.19.1 DC Characteristics

The parameters listed in Table 32-49 on page 2148, with the exception of R_{BIAS} , apply to transmit pins of the Ethernet PHY, which are generally the $EN0TXOP$ and $EN0TXON$ signals during standard operation but can also be the $ENORXIN$ $ENORXIP$ signals if Auto-MDIX is enabled.

Table 32-49. Ethernet PHY DC Characteristics

| Parameter | Parameter Name | Min | Nom | Max | Unit |
|-----------------|---|------|------|------|------------|
| R_{BIAS} | Value of the pull-down resistor on the R_{BIAS} pin | 4.82 | 4.87 | 4.92 | k Ω |
| V_{TPTD_100} | 100M transmit voltage | 0.95 | 1 | 1.05 | V |
| $V_{TPTDSYM}$ | 100M transmit voltage symmetry | -2 | - | 2 | % |
| V_{OVRSH} | Output overshoot | - | - | 5 | % |
| V_{TPTD_10} | 10M transmit voltage | 2.2 | 2.5 | 2.8 | V |
| V_{TH1} | 10Base-T Receive threshold | - | 200 | - | mV |

32.20 Universal Serial Bus (USB) Controller

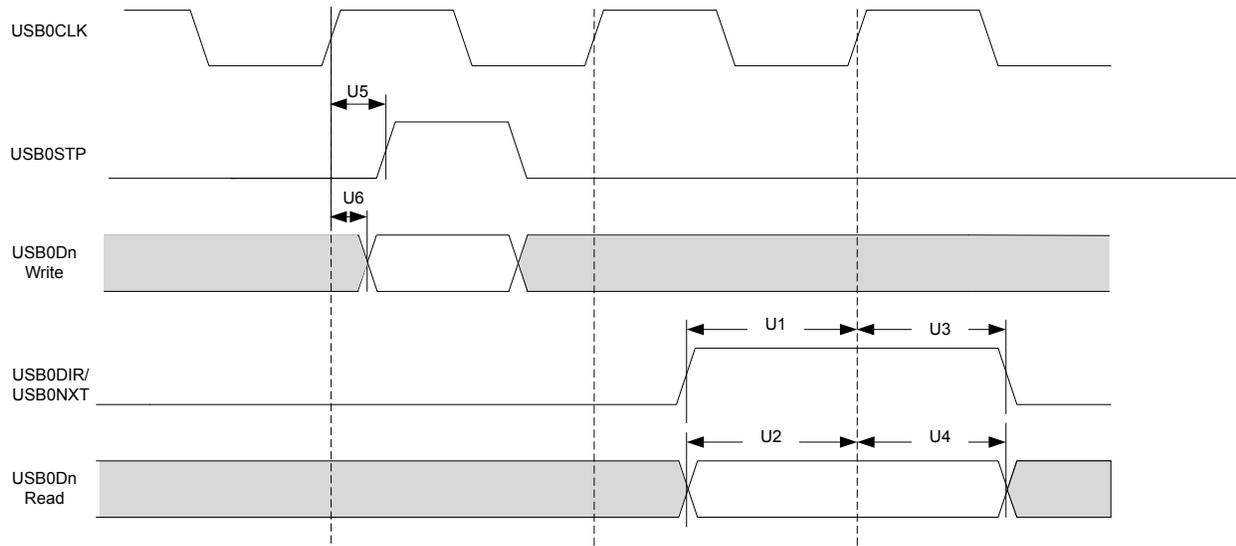

The Tiva™ C Series USB controller electrical specifications are compliant with the *Universal Serial Bus Specification Rev. 2.0* (full-speed and low-speed support) and the *On-The-Go Supplement to the USB 2.0 Specification Rev. 1.0*. Some components of the USB system are integrated within the TM4C129XKCZAD microcontroller and specific to the Tiva™ C Series microcontroller design.

Note: GPIO pin, PB1, which can be configured as the USB0VBUS signal, is the only pin which is 5-V tolerant on the device.

Table 32-65. ULPI Interface Timing

| Parameter No. | Parameter | Parameter Name | Min | Nom | Max | Unit |
|--|------------------|--|-----|-----|------|------|

Figure 32-49. ULPI Interface Timing Diagram

32.21 LCD Controller

The LCD controller consists of two independent controllers, the raster controller and the LCD interface display driver (LIDD) controller. Each controller operates independently from the other and only one of them is active at any given time.

- The LIDD controller supports an asynchronous LCD interface. It provides full-timing programmability of control signals (CS, WE, OE, ALE) and output data. It also supports synchronous interface in Motorola 6800 mode and Intel 8080 mode through the use of the external LCDMCLK output.
- The raster controller handles the synchronous LCD interface. It provides timing and data for constant graphics refresh to a passive display. It supports a wide variety of monochrome and full-color display types and sizes by use of programmable timing controls, a built-in palette, and a gray-scale and serializer. Graphics data is processed and stored in frame buffers. A frame buffer is a contiguous memory block in the system. The μ DMA supplies the graphics data to the raster engine which, in turn, outputs to the external LCD device.

The maximum resolution for the LCD controller is 2048 x 2048 pixels. The maximum frame rate is determined by the image size in combination with the pixel clock rate.

The LCD signals must be configured with a drive strength of 8 mA with slew rate control.

Table 32-66. LCD Controller Load Capacitance Limits

| Parameter | Parameter Name | Condition | Min | Nom | Max | Unit |
|------------|-----------------------------|-------------|-----|-----|-----|------|
| C_{LOAD} | LCD Output Load Capacitance | LIDD mode | 5 | - | 50 | pF |
| | | Raster mode | 3 | - | 30 | pF |

Note: A 25-pF load is assumed for LCD timings.

32.21.1 LCD Interface Display Driver (LIDD Mode)

In LIDD mode, the **LIDDCS0CFG** register allows for full programmability of the read and write strobes, data and enables. In the **LCDCS0CFG** register, the following parameters can be configured with respect to the internal MCLK:

- **WRSU** (bits[31:27]): Number of MCLK cycles that the LCDDATA bus, output enable, ADE, DIR and CS0 signals have to be ready before the write strobe. The minimum value is 0x0.
- **WRDUR** (bits[26:21]): Number of MCLK cycles for which the write strobe is held active when performing a write access. The minimum value is 0x1.
- **WRHOLD** (bits[20:17]): Number of MCLK cycles for which the LCDDATA bus, output enable, ALE, DIR and CS0 signals are held after the write strobe is deasserted when performing a write access. The minimum value is 0x1.
- **RDSU** (bits[16:12]): When performing a read access, this field defines the number of MCLK cycles that the LCDDATA bus, output enable, ALE, DIR and CS0 signals have to be ready before the read strobe is asserted.
- **RDDUR** (bits[11:6]): Number of MCLK cycles for which the read strobe is held active when performing a read access. The minimum value is 0x1.

- RDHOLD (bits[5:2]): Number of MCLK cycles for which the LCDDATA bus, output enable, ALE, DIR and CS0 signals are held after the read strobe is deasserted when performing a read access. The minimum value is 0x1.
- GAP (bits[1:0]): Number of MCLK cycles (GAP + 1) between the end of one CS0 device access and the start of another CS0 devices access unless the two accesses are both reads. In this case, this delay is not incurred. The minimum value is 0x0.

Essentially, output valid/hold and input setup/hold times in LIDD mode are programmed by these fields. In addition, the inherent clock delay from the internal MCLK transition to the signal output adds or subtracts to these programmed times as indicated in the following tables and figures.

Table 32-67. LCD Switching Characteristics

| Parameter No. | Parameter | Parameter Name | Min | Nom | Max | Unit |
|---------------|-----------------------|---|-----|-----|-------|------|
| L1 | T _{CYC} | Internal MCLK cycle time | - | 50 | - | ns |
| L2 | T _{CYCH} | Internal MCLK pulse duration high | - | 25 | - | ns |
| L3 | T _{CYCL} | Internal MCLK pulse duration low | - | 25 | - | ns |
| L4 | T _{DLYVAL} | Delay time from internal MCLK high to LCDDATA[15:0] valid (write) | - | - | 11.6 | ns |
| L5 | T _{DLYINV} | Delay time from internal MCLK high to LCDDATA[15:0] invalid (write) | - | - | 4.0 | ns |
| L6 | T _{DLYHAC} | Delay time, internal MCLK high to LCDAC | - | - | 11.19 | ns |
| L7 | T _{TRANAC} | LCDAC transition time | - | - | 5.9 | ns |
| L8 | T _{DLYFP} | Delay time from internal MCLK high to LCDFP | - | - | 10.5 | ns |
| L9 | T _{TRANFP} | LCDFP transition time | - | - | 5.9 | ns |
| L10 | T _{DLYLP} | Delay time internal MCLK high to LCDLP | - | - | 11.0 | ns |
| L11 | T _{TRANLP} | LCDLP transition time | - | - | 5.9 | ns |
| L12 | T _{DLYCP} | Delay time of internal MCLK to LCDCP | - | - | 8.4 | ns |
| L13 | T _{TRANCP} | LCDCP transition time | - | - | 5.9 | ns |
| L14 | T _{DLYDZ} | Delay time from internal MCLK high to LCDDATA[15:0] high-Z (read cycle) | - | - | 11.7 | ns |
| L15 | T _{DLYDD} | Delay time from internal MCLK high to LCDDATA[15:0] active (read cycle) | - | - | 11.0 | ns |
| L19 | T _{TRANMCLK} | Internal MCLK transition time | - | - | 5.9 | ns |
| L20 | T _{TRANPKT} | LCDDATA transition time from one data packet to next. | - | - | 5.9 | ns |

Table 32-68. Timing Requirements for LCDDATA in LIDD Mode

| Parameter No. | Parameter | Parameter Name | Min | Nom | Max | Unit |
|---------------|------------------------|---|-----|-----|-----|------|
| L16 | T _{STDATA} | LCDDATA[15:0] setup time (read) before internal MCLK high | 20 | - | - | ns |
| L17 | T _{HTDATA} | LCDDATA[15:0] hold time (read) after internal MCLK high | 0 | - | - | ns |
| L18 | T _{TRANRDATA} | LCDDATA read transition time | 5.9 | - | - | ns |

32.21.1.1 Hitachi Mode

Hitachi mode is an asynchronous mode which does not use an external LCDMCLK and allows for full programmability of the read and write strobes, data and enables through the **LIDDCS0CFG** register. Note that in addition to the parameter delays configured in the **LIDDCS0CFG** register, the delay times in the associated figures shown below that are from the internal MCLK to the signal output must be added to the programmed delays for full timing information. All of the parameter values associated with the following figures can be found in Table 32-67 on page 2159 and Table 32-68 on page 2159.

In Figure 32-50 on page 2160, Figure 32-51 on page 2161, and Figure 32-52 on page 2161 the second LCDMCLK is shown as E1 and can be used as the enable strobe for a second display in Hitachi mode. The primary enable strobe is the LCDAC signal.

Note: The acronyms WRSU, WRDUR, WRHOLD and GAP in the following figures correspond to the bitfields of the **LIDDCS0CFG** register described in “LCD Interface Display Driver (LIDD Mode)” on page 2158.

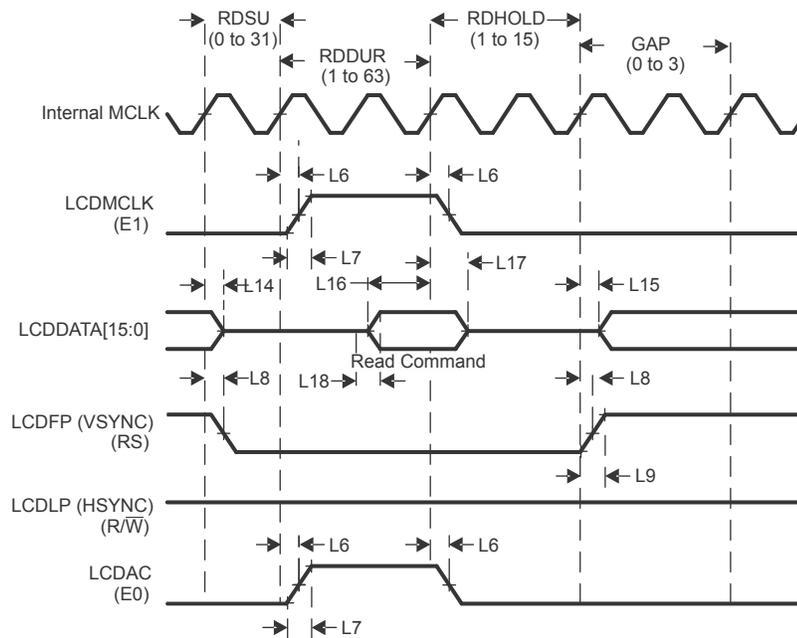

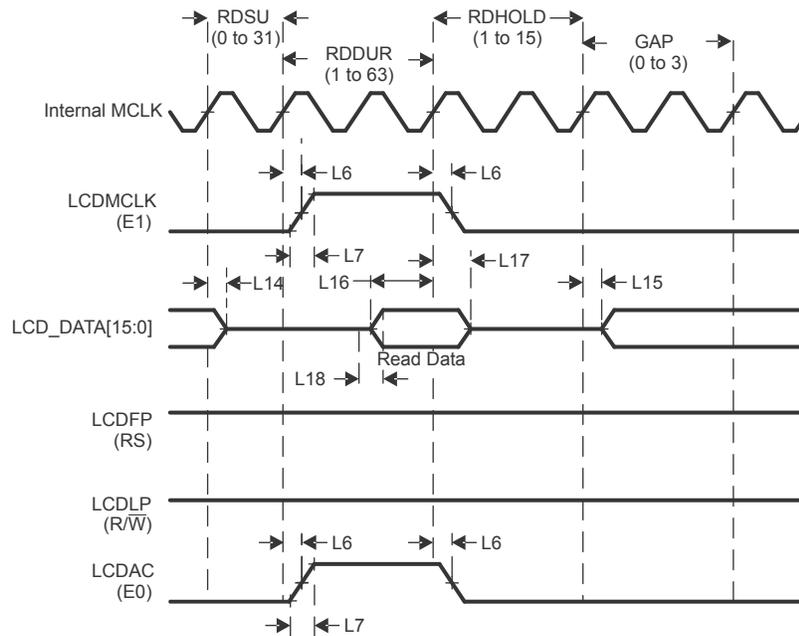

Figure 32-53. Data Read in Hitachi Mode

32.21.1.2 Motorola 6800 Mode

Motorola 6800 mode can be configured to perform asynchronous operations or synchronous operations. When configured in asynchronous mode, `LCDMCLK` is not required, so it performs the CS1 function. When configured in asynchronous mode, `LCDMCLK` is not required, so it performs the CS1 function. When configured in synchronous mode, `MCLK` is available externally through the signal `LCDMCLK`. Note that in asynchronous mode the internal `MCLK` shown represents the internal clock that sequences the other signals. All of the parameter values associated with the following figures can be found in Table 32-67 on page 2159 and Table 32-68 on page 2159.

Note: In asynchronous Motorola 6800 mode, `LCDCP` functions as the read and write strobe. In synchronous mode

Note: The acronyms `WRSU`, `WRDUR`, `WRHOLD` and `GAP` in the following figures correspond to the bitfields of the `LIDDCS0CFG` register described in “LCD Interface Display Driver (LIDD Mode)” on page 2158.

Figure 32-54. Motorola 6800 Graphic Display Mode Write (Synchronous & Asynchronous Operation)

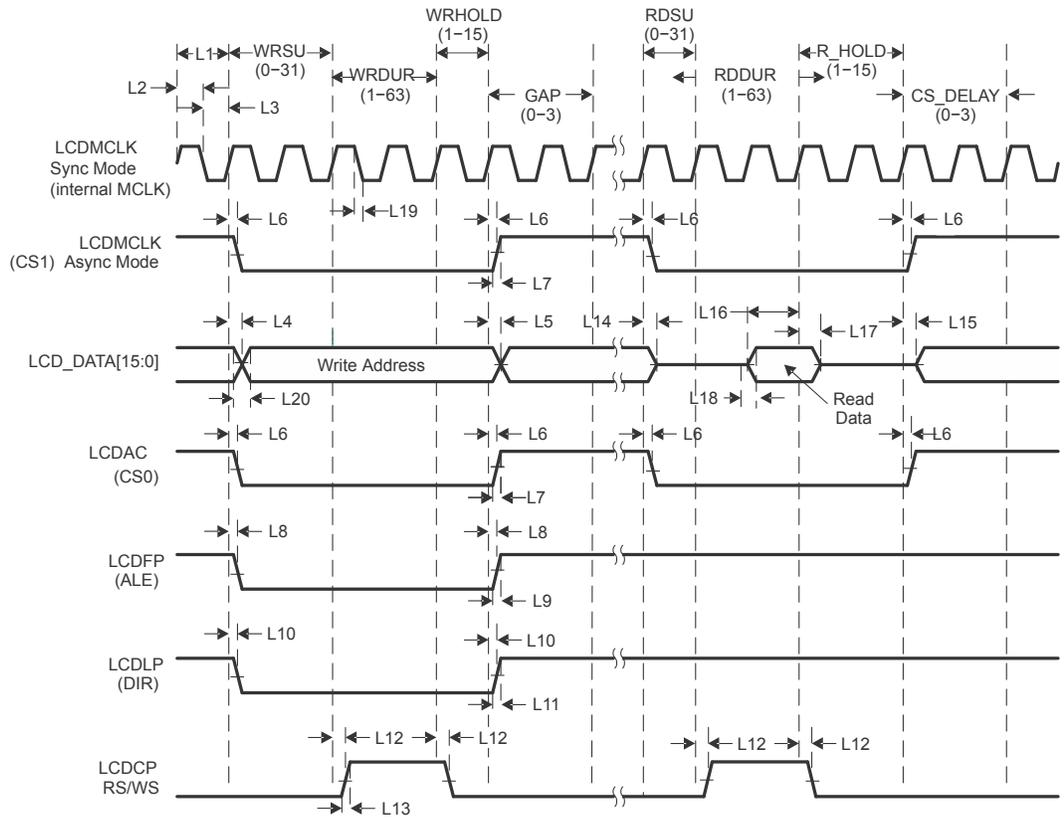

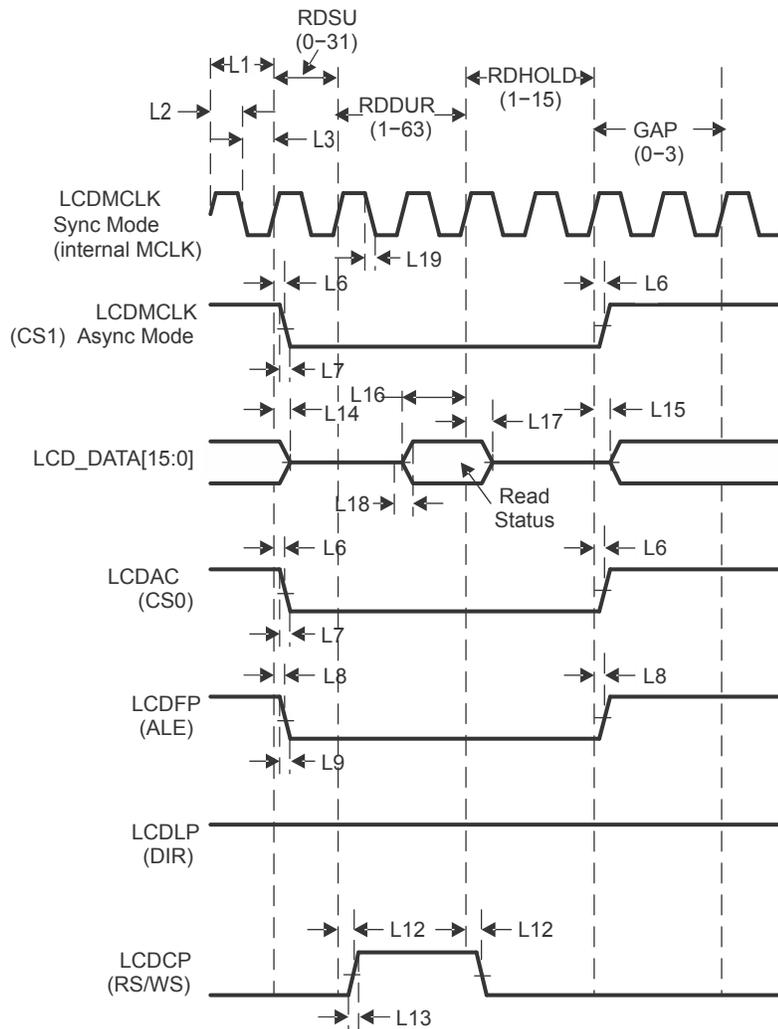

Figure 32-56. Motorola 6800 Graphic Display Mode Status (Synchronous & Asynchronous Operation)

32.21.1.3 Intel 8080 Mode

Intel mode can be configured to perform asynchronous operations or synchronous operations. When configured in asynchronous mode, `LCDMCLK` is not required, so it performs the CS1 function. When configured in synchronous mode, `MCLK` is available externally through the signal `LCDMCLK`. Note that in asynchronous mode the internal `MCLK` shown represents the internal clock that sequences the other signals. All of the parameter values associated with the following figures can be found in Table 32-67 on page 2159 and Table 32-68 on page 2159.

Note: The acronyms `WRSU`, `WRDUR`, `WRHOLD` and `GAP` in the following figures correspond to the bitfields of the `LIDDCS0CFG` register described in “LCD Interface Display Driver (LIDD Mode)” on page 2158.

32.21.2 LCD Raster Mode

The following table depicts the LCD Raster Mode Characteristics.

Table 32-69. Switching Characteristics Over Recommended Operating Characteristics for LCD Raster Mode

| Parameter No. | Parameter | Parameter Name | Min | Nom | Max | Unit |
|---------------|--------------|--|-------|-----|-----|------|
| L21 | T_{CYC} | LCDCP cycle time | 16.67 | - | - | ns |
| L22 | T_{PH} | LCDCP pulse width high | 8.33 | - | - | ns |
| L23 | T_{PL} | LCDCP pulse width low | 8.33 | - | - | ns |
| L24 | T_{DLYVAL} | Delay time from LCDCP to LCDDATA[23:0] valid (write) | 2.0 | - | 7.3 | ns |

Table 32-69. Switching Characteristics Over Recommended Operating Characteristics for LCD Raster Mode (continued)

| Parameter No. | Parameter | Parameter Name | Min | Nom | Max | Unit |
|---------------|-----------------------|--|-----|-----|-----|------|
| L25 | T _{DLYINV} | Delay time from LCDCP to LCDDATA[23:0] invalid (write) | 2.0 | - | 7.3 | ns |
| L26 | T _{DLYHAC} | Delay time, LCDCP to LCDAC | 1.9 | - | 7.0 | ns |
| L27 | T _{TRANAC} | LCDAC transition time | 0.5 | - | 3.3 | ns |
| L28 | T _{DLYFP} | Delay time from LCDCP high to LCDFP | 1.7 | - | 6.5 | ns |
| L29 | T _{TRANFP} | LCDFP transition time | 0.5 | - | 3.3 | ns |
| L30 | T _{DLYLP} | Delay time from LCDCP high to LCDLP | 2.0 | - | 6.8 | ns |
| L31 | T _{TRANLP} | LCDLP transition time | 0.5 | - | 3.3 | ns |
| L32 | T _{TRANCP} | LCDCP transition time | 0.5 | - | 3.3 | ns |
| L33 | T _{TRANDATA} | LCDDATA transition time | 0.5 | - | 3.3 | ns |

Frame-to-frame timing is derived through the following parameters in the **LCD Raster Timing 1 (LCDRASTRIM1)** register:

- Vertical front porch (VFP)
- Vertical sync pulse width (VSW)
- Vertical back porch (VBP)
- Lines per panel (MSBLPP + LPP)

Line-to-line timing is derived through the following parameters in the **LCD Raster Timing 0 (LCDRASTRIM0)** register:

- Horizontal front porch (HFP)
- Horizontal sync pulse width (HSW)
- Horizontal back porch (HBP)
- Pixels per panel (PPLMSB + PPLLSB)

LCDAC timing is derived through the following parameter in the **LCD Raster Timing 2 (LCDRASTRIM2)** register:

- AC bias frequency (ACBF)

The display format produced in raster mode is shown in Figure 32-60 on page 2170. An entire frame is delivered one line at a time. The first line delivered starts at data pixel (1, 1) and ends at data pixel (P, 1). The last line delivered starts at data pixel (1, L) and ends at data pixel (P, L). The beginning of each new frame is denoted by the activation of IO signal LCDFP (VSYNC). The beginning of each new line is denoted by the activation of IO signal LCDLP (HSYNC).

32.22 Analog Comparator

Table 32-70. Analog Comparator Characteristics^{ab}

| Parameter | Parameter Name | Min | Nom | Max | Unit |
|----------------------|---|------|----------|------------|---------|
| V_{INP}, V_{INN}^c | Input voltage range | GNDA | - | V_{DDA} | V |
| V_{CM} | Input common mode voltage range | GNDA | - | V_{DDA} | V |
| V_{OS} | Input offset voltage | - | ± 10 | $\pm 50^d$ | mV |
| I_{INP}, I_{INN} | Input leakage current over full voltage range | - | - | 2.0 | μA |
| C_{MRR} | Common mode rejection ratio | - | 50 | - | dB |
| T_{RT} | Response time | - | - | 1.0^e | μs |
| T_{MC} | Comparator mode change to Output Valid | - | - | 10 | μs |

- a. Best design practices suggest that static or quiet digital I/O signals be configured adjacent to sensitive analog inputs to reduce capacitive coupling and cross talk.
- b. To achieve best analog results, the source resistance driving the analog inputs, V_{INP} and V_{INN} , should be kept low.
- c. The external voltage inputs to the Analog Comparator are designed to be highly sensitive and can be affected by external noise on the board. For this reason, V_{INP} and V_{INN} must be set to different voltage levels during idle states to ensure the analog comparator triggers are not enabled. If an internal voltage reference is used, it should be set to a mid-supply level. When operating in Sleep/Deep-Sleep modes, the Analog Comparator module should be disabled or the external voltage inputs set to different levels (greater than the input offset voltage) to achieve minimum current draw.
- d. Measured at $V_{REF}=100$ mV.
- e. Measured at external $V_{REF}=100$ mV, input signal switching from 75 mV to 125 mV.

Table 32-71. Analog Comparator Voltage Reference Characteristics

| Parameter | Parameter Name | Min | Nom | Max | Unit |
|-----------|------------------------------|-----|-----------------|----------------|------|
| R_{HR} | Resolution in high range | - | $V_{DDA}/29.4$ | - | V |
| R_{LR} | Resolution in low range | - | $V_{DDA}/22.12$ | - | V |
| A_{HR} | Absolute accuracy high range | - | - | $\pm R_{HR}/2$ | V |
| A_{LR} | Absolute accuracy low range | - | - | $\pm R_{LR}/2$ | V |

32.23 Pulse-Width Modulator (PWM)

Table 32-74. PWM Timing Characteristics

| Parameter | Parameter Name | Min | Nom | Max | Unit |
|--------------|--|-----|-----|--------------------|-------------------|
| T_{FLTW} | Minimum Fault Pulse Width | 2 | - | - | PWM clock periods |
| T_{FLTMAX} | MnFAULTn Assertion to PWM Inactive ^a | - | - | 24 + (1 PWM clock) | ns |
| T_{FLTMIN} | MnFAULTn De-Assertion to PWM Active ^b | 5 | - | - | ns |

a. This parameter value can vary depending on the PWM clock frequency which is controlled by the System Clock and a programmable divider field in the **PWMCC** register.

b. The latch and minimum fault period functions that can be enabled in the **PWMnCTL** register can change the timing of this parameter.

32.24 Current Consumption

Table 32-76 on page 2182 shows the amount of current consumption that specific peripherals contribute to the Run mode current consumption numbers shown in Table 32-75 on page 2178. If these peripherals are not powered, then the peripheral current consumption values can be subtracted from the Run mode numbers displayed in Table 32-75 on page 2178.

Table 32-75. Current Consumption^{ab}

| Parameter | Parameter Name | Conditions | System Clock | | Nom | | | | Max | | Unit |

a. Total current in RUN, SLEEP and DEEPSLEEP modes is the sum of I_{DDPHY}, I_{DD} and I_{DDA}.

b. For Peripherals = All OFF, the clocks to all peripherals are turned off and the peripherals are powered down, if capable (see the section called "Peripheral Power Control" on page 254).

c. Applicable to extended temperature devices only.

- d. Note that if the MOSC is the source of the Run-mode system clock and is powered down in Sleep mode, wake time is increased by T_{MOSC_SETTLE} .
- e. To achieve the lowest possible Deep-Sleep current, one or more wait states must be configured in the **MEMTIMO** register. If there are no wait states applied in Run mode, then lowest possible Deep-Sleep current is not achieved.
- f. See the section called "LDO Power Control" on page 255 for information on lowering the LDO voltage to 0.9 V.

Table 32-76. Peripheral Current Consumption

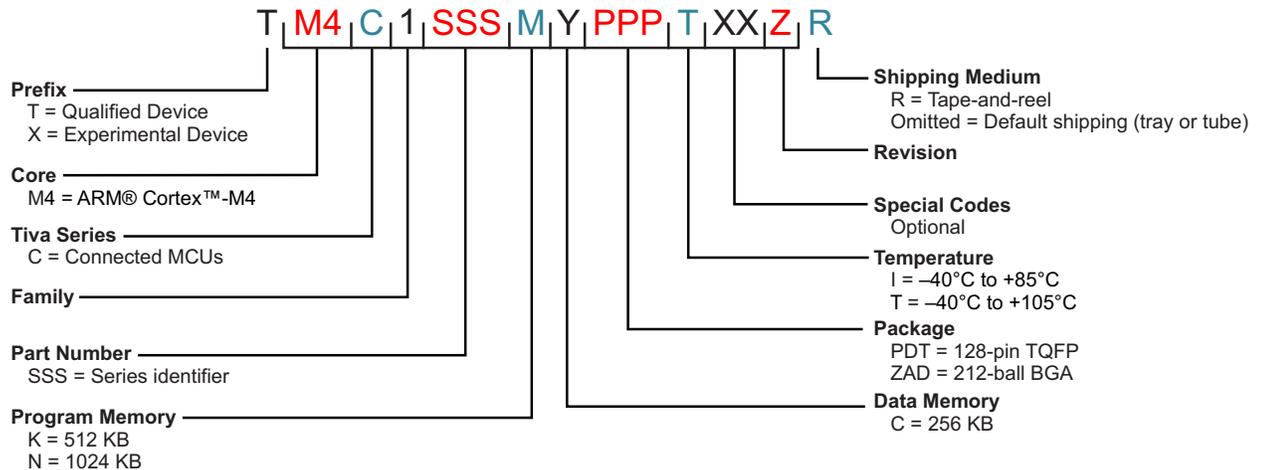

| Parameter | Parameter Name | Conditions | System Clock | Nom | Units |
|-----------------|--|---|-------------------------|-----|-------|
| I_{DDUSB} | USB (including USB PHY) run mode current | $V_{DD} = 3.3\text{ V}$ $V_{DDA} = 3.3\text{ V}$ | 120 MHz (MOSC with PLL) | 4.0 | mA |
| I_{DDEMAC} | Ethernet MAC run mode current | $V_{DD} = 3.3\text{ V}$ $V_{DDA} = 3.3\text{ V}$ | 120 MHz (MOSC with PLL) | 1.9 | mA |
| $I_{DDEMACPHY}$ | Ethernet MAC and PHY run mode current | $V_{DD} = 3.3\text{ V}$ $V_{DDA} = 3.3\text{ V}$ | 120 MHz (MOSC with PLL) | 30 | mA |

A Package Information

A.1 Orderable Devices

The figure below defines the full set of orderable part numbers for the TM4C129x Series. See the Package Option Addendum for the complete list of valid orderable part numbers for the TM4C129XKCZAD microcontroller.

Figure A-1. Key to Part Numbers

A.2 Device Nomenclature

To designate the stages in the product development cycle, TI assigns prefixes to the part numbers of all microcontroller (MCU) devices. Each Tiva™ C Series family member has one of two prefixes: XM4C or TM4C. These prefixes represent evolutionary stages of product development from engineering prototypes (XM4C) through fully qualified production devices (TM4C).

Device development evolutionary flow:

- XM4C — Experimental device that is not necessarily representative of the final device's electrical specifications and may not use production assembly flow.
- TM4C — Production version of the silicon die that is fully qualified.

XM4C devices are shipped against the following disclaimer:

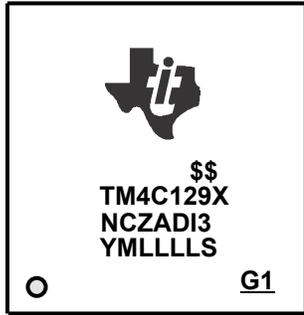

"Developmental product is intended for internal evaluation purposes."

TM4C devices have been characterized fully, and the quality and reliability of the device have been demonstrated fully. TI's standard warranty applies.

Predictions show that prototype devices (XM4C) have a greater failure rate than the standard production devices. Texas Instruments recommends that these devices not be used in any production system because their expected end-use failure rate still is undefined. Only qualified production devices are to be used.

A.3 Device Markings

The figure below shows an example of the Tiva™ microcontroller package symbolization.

This identifying number contains the following information:

- **Lines 1 and 5:** Internal tracking numbers
- **Lines 2 and 3:** Part number

For example, TM4C129X on the second line followed by NCZADI3 on the third line indicates orderable part number TM4C129XNCZADI3. Note that the first letter in the part number indicates the product status. A T indicates the part is fully qualified and released to production; an X indicates the part is experimental (pre-production) and requires a waiver. The silicon revision number is the last number in the part number, in this example, 3. The **DID0** register identifies the version of the microcontroller, as shown in the table below. Combined, the MAJOR and MINOR bit fields indicate the die revision and part revision numbers.

| MAJOR Bitfield Value | MINOR Bitfield Value | Die Revision | Part Revision |
|----------------------|----------------------|--------------|---------------|
| 0x0 | 0x0 | A0 | 1 |
| 0x0 | 0x1 | A1 | 2 |
| 0x0 | 0x2 | A2 | 3 |

- **Line 4:** Date code

The first two characters on the fourth line indicate the date code, followed by internal tracking numbers. The two-digit date code YM indicates the last digit of the year, then the month. For example, a 34 for the first two digits of the fourth line indicates a date code of April 2013.

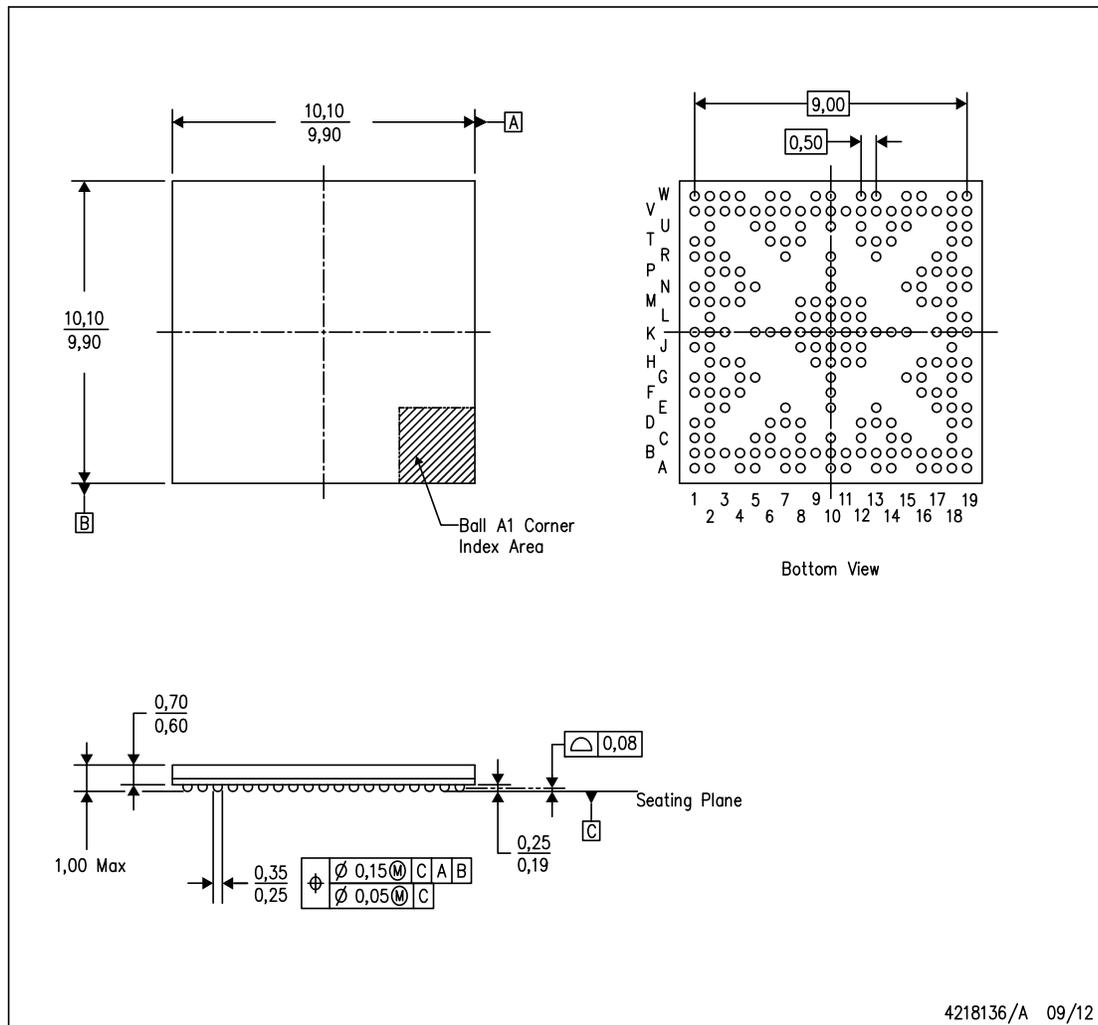

A.4 Packaging Diagram

Figure A-2. TM4C129XKCZAD 212-Ball BGA Package Diagram

MECHANICAL DATA

ZAD (S-PBGA-N212)

PLASTIC BALL GRID ARRAY

- NOTES:
- All linear dimensions are in millimeters. Dimensioning and tolerancing per ASME Y14.5M-1994.
 - This drawing is subject to change without notice.
 - This is a Pb-free solder ball design.

PACKAGING INFORMATION

| Orderable part number | Status (1) | Material type (2) | Package Pins | Package qty Carrier | RoHS (3) | Lead finish/ Ball material (4) | MSL rating/ Peak reflow (5) | Op temp (°C) | Part marking (6) |
|----------------------------------|---------------|----------------------|-------------------|-------------------------|-------------|--------------------------------------|-----------------------------------|--------------|---------------------|
| TM4C129XKCZADI3 | Active | Production | NFBGA (ZAD) 212 | 184 JEDEC TRAY (10+1) | Yes | SNAGCU | Level-3-260C-168 HR | -40 to 85 | TM4C129 XKCZADI3 |
| TM4C129XKCZADI3.B | Active | Production | NFBGA (ZAD) 212 | 184 JEDEC TRAY (10+1) | Yes | SNAGCU | Level-3-260C-168 HR | -40 to 85 | TM4C129 XKCZADI3 |
| TM4C129XKCZADI3R | Obsolete | Production | NFBGA (ZAD) 212 | - | - | Call TI | Call TI | -40 to 85 | TM4C129 XKCZADI3 |
| TM4C129XKCZADT3 | Active | Production | NFBGA (ZAD) 212 | 184 JEDEC TRAY (10+1) | Yes | SNAGCU | Level-3-260C-168 HR | -40 to 105 | TM4C129 XKCZADT3 |
| TM4C129XKCZADT3.B | Active | Production | NFBGA (ZAD) 212 | 184 JEDEC TRAY (10+1) | Yes | SNAGCU | Level-3-260C-168 HR | -40 to 105 | TM4C129 XKCZADT3 |

(1) **Status:** For more details on status, see our [product life cycle](#).

(2) **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

(3) **RoHS values:** Yes, No, RoHS Exempt. See the [TI RoHS Statement](#) for additional information and value definition.

(4) **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

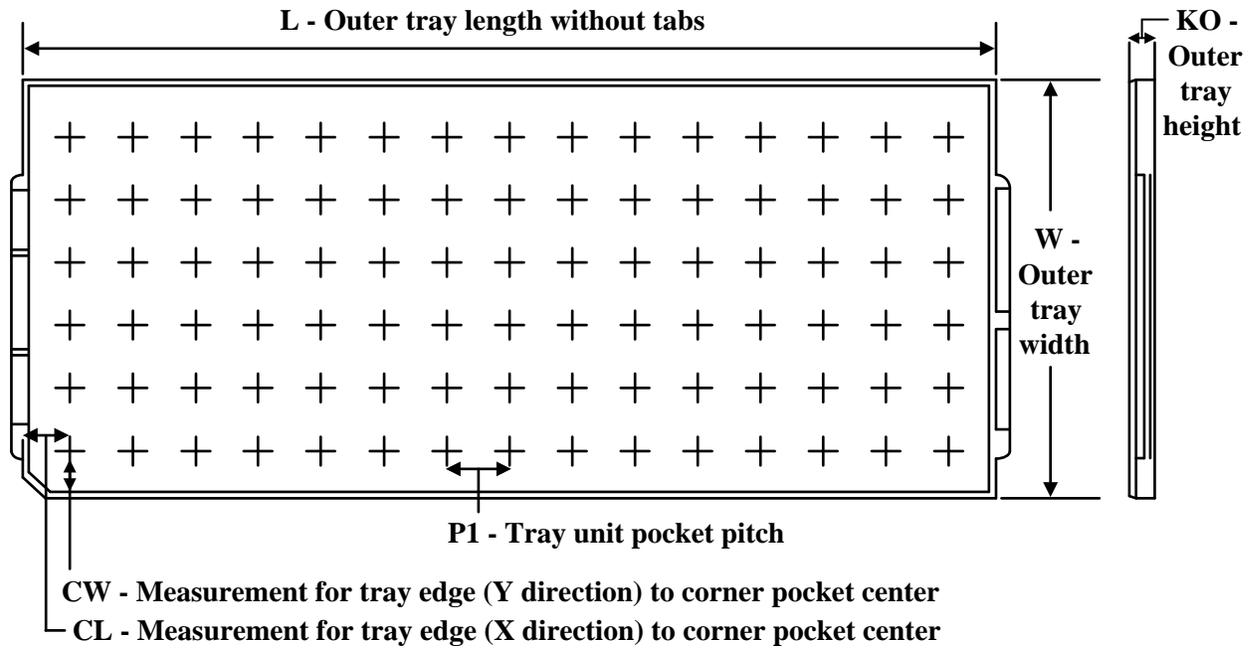

(5) **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

(6) **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.

Important Information and Disclaimer: The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

TRAY

Chamfer on Tray corner indicates Pin 1 orientation of packed units.

You are solely responsible for (1) selecting the appropriate TI products for your application, (2) designing, validating and testing your application, and (3) ensuring your application meets applicable standards, and any other safety, security, regulatory or other requirements.

These resources are subject to change without notice. TI grants you permission to use these resources only for development of an application that uses the TI products described in the resource. Other reproduction and display of these resources is prohibited. No license is granted to any other TI intellectual property right or to any third party intellectual property right. TI disclaims responsibility for, and you fully indemnify TI and its representatives against any claims, damages, costs, losses, and liabilities arising out of your use of these resources.

TI's products are provided subject to [TI's Terms of Sale](#), [TI's General Quality Guidelines](#), or other applicable terms available either on [ti.com](#) or provided in conjunction with such TI products. TI's provision of these resources does not expand or otherwise alter TI's applicable warranties or warranty disclaimers for TI products. Unless TI explicitly designates a product as custom or customer-specified, TI products are standard, catalog, general purpose devices.

TI objects to and rejects any additional or different terms you may propose.
