TMS320VC5410A
Fixed-Point Digital Signal Processor

Data Manual

Literature Number: SPRS139I
November 2000 – Revised October 2008

Revision History

NOTE: Page numbers for previous revisions may differ from page numbers in the current version.

This data sheet revision history highlights the technical changes made to the SPRS139H device-specific data sheet to make it an SPRS139I revision.

Scope: This document has been reviewed for technical accuracy; the technical content is up-to-date as of the specified release date with the following corrections.

ADDITIONS/CHANGES/DELETIONS
Table 2-2, Signal Descriptions: • Updated DESCRIPTION of $\overline{\text{TRST}}$ • Added footnote about $\overline{\text{TRST}}$

List of Tables

1 TMS320VC5410A Features

- **Advanced Multibus Architecture With Three Separate 16-Bit Data Memory Buses and One Program Memory Bus**
- **40-Bit Arithmetic Logic Unit (ALU) Including a 40-Bit Barrel Shifter and Two Independent 40-Bit Accumulators**
- **17- × 17-Bit Parallel Multiplier Coupled to a 40-Bit Dedicated Adder for Non-Pipelined Single-Cycle Multiply/Accumulate (MAC) Operation**
- **Compare, Select, and Store Unit (CSSU) for the Add/Compare Selection of the Viterbi Operator**
- **Exponent Encoder to Compute an Exponent Value of a 40-Bit Accumulator Value in a Single Cycle**
- **Two Address Generators With Eight Auxiliary Registers and Two Auxiliary Register Arithmetic Units (ARAUs)**
- **Data Bus With a Bus Holder Feature**
- **Extended Addressing Mode for 8M × 16-Bit Maximum Addressable External Program Space**
- **64K × 16-Bit On-Chip RAM Composed of Eight Blocks of 8K × 16-Bit On-Chip Dual-Access Program/Data RAM**
- **16K × 16-Bit On-Chip ROM Configured for Program Memory**
- **Enhanced External Parallel Interface (XIO2)**
- **Single-Instruction-Repeat and Block-Repeat Operations for Program Code**
- **Block-Memory-Move Instructions for Better Program and Data Management**
- **Instructions With a 32-Bit Long Word Operand**
- **Instructions With Two- or Three-Operand Reads**
- **Arithmetic Instructions With Parallel Store and Parallel Load**
- **Conditional Store Instructions**
- **Fast Return From Interrupt**
- **On-Chip Peripherals**
  - **Software-Programmable Wait-State Generator and Programmable Bank-Switching**
  - **On-Chip Programmable Phase-Locked Loop (PLL) Clock Generator With Internal Oscillator or External Clock Source**(1)
  - **One 16-Bit Timer**
  - **Six-Channel Direct Memory Access (DMA) Controller**
  - **Three Multichannel Buffered Serial Ports (McBSPs)**
  - **8/16-Bit Enhanced Parallel Host-Port Interface (HPI8/16)**
- **Power Consumption Control With IDLE1, IDLE2, and IDLE3 Instructions With Power-Down Modes**
- **CLKOUT Off Control to Disable CLKOUT**
- **On-Chip Scan-Based Emulation Logic, IEEE Std 1149.1**(2) **(JTAG) Boundary Scan Logic**
- **144-Pin Ball Grid Array (BGA) (GGU Suffix)**
- **144-Pin Low-Profile Quad Flatpack (LQFP) (PGE Suffix)**
- **6.25-ns Single-Cycle Fixed-Point Instruction Execution Time (160 MIPS)**
- **8.33-ns Single-Cycle Fixed-Point Instruction Execution Time (120 MIPS)**
- **3.3-V I/O Supply Voltage (160 and 120 MIPS)**
- **1.6-V Core Supply Voltage (160 MIPS)**
- **1.5-V Core Supply Voltage (120 MIPS)**

(1) The on-chip oscillator is not available on all 5410A devices. For applicable devices, see the *TMS320VC5410A Digital Signal Processor Silicon Errata* (literature number SPRZ187).
(2) IEEE Standard 1149.1-1990 Standard-Test-Access Port and Boundary Scan Architecture.

2 Introduction

This section lists the pin assignments and describes the function of each pin. This data manual also provides a detailed description section, electrical specifications, parameter measurement information, and mechanical data about the available packaging.

NOTE

This data manual is designed to be used in conjunction with the *TMS320C54x™ DSP Functional Overview* (literature number SPRU307).

2.1 Description

The TMS320VC5410A fixed-point, digital signal processor (DSP) (hereafter referred to as the 5410A unless otherwise specified) is based on an advanced modified Harvard architecture that has one program memory bus and three data memory buses. This processor provides an arithmetic logic unit (ALU) with a high degree of parallelism, application-specific hardware logic, on-chip memory, and additional on-chip peripherals. The basis of the operational flexibility and speed of this DSP is a highly specialized instruction set.

Separate program and data spaces allow simultaneous access to program instructions and data, providing a high degree of parallelism. Two read operations and one write operation can be performed in a single cycle. Instructions with parallel store and application-specific instructions can fully utilize this architecture. In addition, data can be transferred between data and program spaces. Such parallelism supports a powerful set of arithmetic, logic, and bit-manipulation operations that can all be performed in a single machine cycle. The 5410A also includes the control mechanisms to manage interrupts, repeated operations, and function calls.

2.2 Terminal/Pin Assignments

Figure 2-1 illustrates the ball locations for the 144-pin ball grid array (BGA) package and is used in conjunction with Table 2-1 to locate signal names and ball grid numbers. Figure 2-2 provides the pin assignments for the 144-pin low-profile quad flatpack (LQFP) package.

2.2.1 Terminal Assignments for the GGU Package

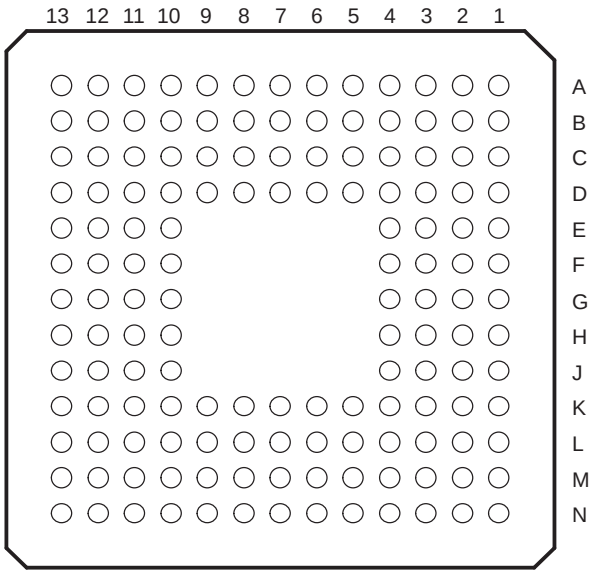

Figure 2-1. 144-Ball GGU MicroStar BGA™ (Bottom View)

Table 2-1 lists each signal name and BGA ball number for the 144-pin TMS320VC5410AGGU package. Table 2-2 lists each terminal name, terminal function, and operating modes for the TMS320VC5410A. DV_{DD} is the power supply for the I/O pins while CV_{DD} is the power supply for the core CPU. DV_{SS} is the ground for the I/O pins while CV_{SS} is the ground for the core CPU. The DV_{SS} and CV_{SS} pins can be connected to a common ground plane in a system.

Table 2-1. Terminal Assignments

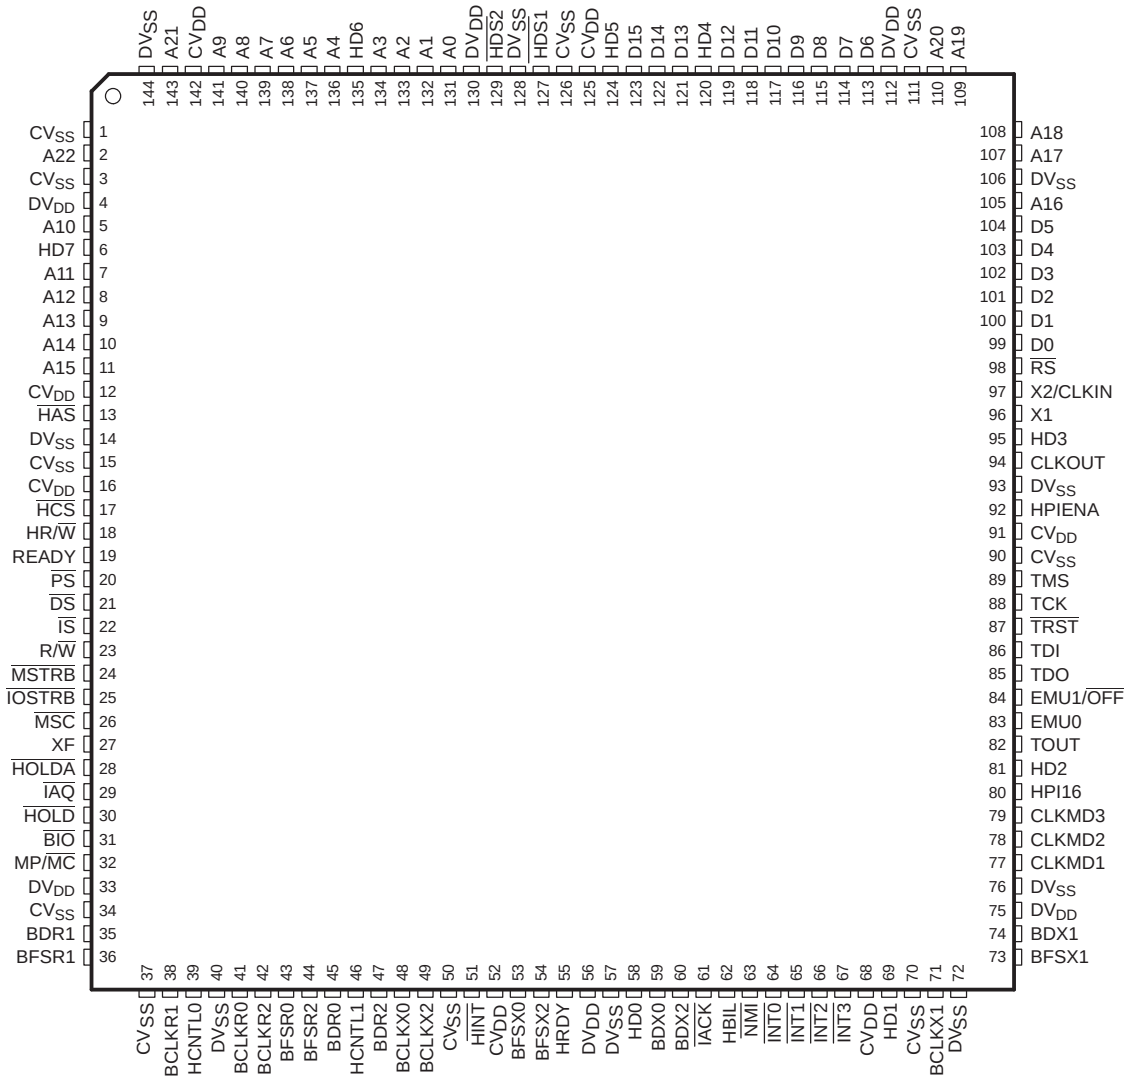
2.2.2 Pin Assignments for the PGE Package

The TMS320VC5410APGE 144-pin low-profile quad flatpack (LQFP) pin assignments are shown in Figure 2-2.



A. DV_{DD} is the power supply for the I/O pins while CV_{DD} is the power supply for the core CPU. DV_{SS} is the ground for the I/O pins while CV_{SS} is the ground for the core CPU. The DV_{SS} and CV_{SS} pins can be connected to a common ground plane in a system.

Figure 2-2. 144-Pin PGE Low-Profile Quad Flatpack (Top View)

2.3 Signal Descriptions

Table 2-2 lists each signal, function, and operating mode(s) grouped by function. See Section 2.2 for exact pin locations based on package type.

Table 2-2. Signal Descriptions

TERMINAL NAME	I/O(1)	DESCRIPTION
DATA SIGNALS		
A22 (MSB) A21 A20 A19 A18 A17 A16 A15 A14 A13 A12 A11 A10 A9 A8 A7 A6 A5 A4 A3 A2 A1 A0 (LSB)	I/O/Z(2)(3)	Parallel address bus A22 [most significant bit (MSB)] through A0 [least significant bit (LSB)]. The sixteen LSB lines, A0 to A15, are multiplexed to address external memory (program, data) or I/O. The seven MSB lines, A16 to A22, address external program space memory. A22-A0 is placed in the high-impedance state in the hold mode. A22-A0 also goes into the high-impedance state when $\overline{OFF}$ is low. A16-A0 are inputs in HPI16 mode. These pins can be used to address internal memory via the host-port interface (HPI) when the HPI16 pin is high. These pins also have Schmitt trigger inputs. The address bus has a bus holder feature that eliminates passive components and the power dissipation associated with them. The bus holder keeps the address bus at the previous logic level when the bus goes into a high-impedance state.
D15 (MSB) D14 D13 D12 D11 D10 D9 D8 D7 D6 D5 D4 D3 D2 D1 D0 (LSB)	I/O/Z(2)(3)	Parallel data bus D15 (MSB) through D0 (LSB). D15-D0 is multiplexed to transfer data between the core CPU and external data/program memory or I/O devices or HPI in HPI16 mode (when HPI16 pin is high). D15-D0 is placed in the high-impedance state when not outputting data or when $\overline{RS}$ or $\overline{HOLD}$ is asserted. D15-D0 also goes into the high-impedance state when $\overline{OFF}$ is low. These pins also have Schmitt trigger inputs. The data bus has a bus holder feature that eliminates passive components and the power dissipation associated with them. The bus holder keeps the data bus at the previous logic level when the bus goes into the high-impedance state. The bus holders on the data bus can be enabled/disabled under software control.
INITIALIZATION, INTERRUPT AND RESET OPERATIONS		
$\overline{IACK}$	O/Z	Interrupt acknowledge signal. $\overline{IACK}$ indicates receipt of an interrupt and that the program counter is fetching the interrupt vector location designated by A15-A0. $\overline{IACK}$ also goes into the high-impedance state when $\overline{OFF}$ is low.
$\overline{INT0}$(2) $\overline{INT1}$(2) $\overline{INT2}$(2) $\overline{INT3}$(2)	I	External user interrupt inputs. $\overline{INT0}$-$\overline{INT3}$ are maskable and are prioritized by the interrupt mask register (IMR) and the interrupt mode bit. $\overline{INT0}$ -$\overline{INT3}$ can be polled and reset by way of the interrupt flag register (IFR).
$\overline{NMI}$(2)	I	Nonmaskable interrupt. $\overline{NMI}$ is an external interrupt that cannot be masked by way of the INTM or the IMR. When $\overline{NMI}$ is activated, the processor traps to the appropriate vector location.
$\overline{RS}$(2)	I	Reset. $\overline{RS}$ causes the digital signal processor (DSP) to terminate execution and forces the program counter to 0FF80h. When $\overline{RS}$ is brought to a high level, execution begins at location 0FF80h of program memory. $\overline{RS}$ affects various registers and status bits.

(1) I = Input, O = Output, Z = High-impedance, S = Supply
(2) These pins have Schmitt trigger inputs.
(3) This pin has an internal bus holder controlled by way of the BSCR register.

Table 2-2. Signal Descriptions (continued)

TERMINAL NAME	I/O[1]	DESCRIPTION
MP/$\overline{MC}$	I	Microprocessor/microcomputer mode select. If active low at reset, microcomputer mode is selected, and the internal program ROM is mapped into the upper 16K words of program memory space. If the pin is driven high during reset, microprocessor mode is selected, and the on-chip ROM is removed from program space. This pin is only sampled at reset, and the MP/$\overline{MC}$ bit of the processor mode status (PMST) register can override the mode that is selected at reset.
MULTIPROCESSING SIGNALS		
$\overline{BIO}$[2]	I	Branch control. A branch can be conditionally executed when $\overline{BIO}$ is active. If low, the processor executes the conditional instruction. The $\overline{BIO}$ condition is sampled during the decode phase of the pipeline for the XC instruction, and all other instructions sample $\overline{BIO}$ during the read phase of the pipeline.
XF	O/Z	External flag output (latched software-programmable signal). XF is set high by the SSBX XF instruction, set low by RSBX XF instruction or by loading ST1. XF is used for signaling other processors in multiprocessor configurations or used as a general-purpose output pin. XF goes into the high-impedance state when $\overline{OFF}$ is low, and is set high at reset.
MEMORY CONTROL SIGNALS		
$\overline{DS}$ $\overline{PS}$ $\overline{IS}$	O/Z	Data, program, and I/O space select signals. $\overline{DS}$, $\overline{PS}$, and $\overline{IS}$ are always high unless driven low for communicating to a particular external space. Active period corresponds to valid address information. $\overline{DS}$, $\overline{PS}$, and $\overline{IS}$ are placed into the high-impedance state in the hold mode; these signals also go into the high-impedance state when $\overline{OFF}$ is low.
$\overline{MSTRB}$	O/Z	Memory strobe signal. $\overline{MSTRB}$ is always high unless low-level asserted to indicate an external bus access to data or program memory. $\overline{MSTRB}$ is placed in the high-impedance state in the hold mode; it also goes into the high-impedance state when $\overline{OFF}$ is low.
READY	I	Data ready. READY indicates that an external device is prepared for a bus transaction to be completed. If the device is not ready (READY is low), the processor waits one cycle and checks READY again. Note that the processor performs ready detection if at least two software wait states are programmed. The READY signal is not sampled until the completion of the software wait states.
R/$\overline{W}$	O/Z	Read/write signal. R/$\overline{W}$ indicates transfer direction during communication to an external device. R/$\overline{W}$ is normally in the read mode (high), unless it is asserted low when the DSP performs a write operation. R/$\overline{W}$ is placed in the high-impedance state in the hold mode; and it also goes into the high-impedance state when $\overline{OFF}$ is low.
$\overline{IOSTRB}$	O/Z	I/O strobe signal. $\overline{IOSTRB}$ is always high unless low-level asserted to indicate an external bus access to an I/O device. $\overline{IOSTRB}$ is placed in the high-impedance state in the hold mode; it also goes into the high-impedance state when $\overline{OFF}$ is low.
$\overline{HOLD}$	I	Hold input. $\overline{HOLD}$ is asserted to request control of the address, data, and control lines. When acknowledged by the 5410A, these lines go into the high-impedance state.
$\overline{HOLDA}$	O/Z	Hold acknowledge. $\overline{HOLDA}$ indicates to the external circuitry that the processor is in a hold state and that the address, data, and control lines are in the high-impedance state, allowing them to be available to the external circuitry. $\overline{HOLDA}$ also goes into the high-impedance state when $\overline{OFF}$ is low. This pin is driven high during reset.
$\overline{MSC}$	O/Z	Microstate complete. $\overline{MSC}$ indicates completion of all software wait states. When two or more software wait states are enabled, the $\overline{MSC}$ pin goes active at the beginning of the first software wait state and goes inactive high at the beginning of the last software wait state. If connected to the READY input, $\overline{MSC}$ forces one external wait state after the last internal wait state is completed. $\overline{MSC}$ also goes into the high-impedance state when $\overline{OFF}$ is low.
$\overline{IAQ}$	O/Z	Instruction acquisition signal. $\overline{IAQ}$ is asserted (active low) when there is an instruction address on the address bus and goes into the high-impedance state when $\overline{OFF}$ is low.
TIMER SIGNALS		
CLKOUT	O/Z	Clock output signal. CLKOUT can represent the machine-cycle rate of the CPU divided by 1, 2, 3, or 4 as configured in the bank-switching control register (BSCR). Following reset, CLKOUT represents the machine-cycle rate divided by 4.
CLKMD1[2] CLKMD2[2] CLKMD3[2]	I	Clock mode select signals. CLKMD1-CLKMD3 allow the selection and configuration of different clock modes such as crystal, external clock, and PLL mode. The external CLKMD1-CLKMD3 pins are sampled to determine the desired clock generation mode while $\overline{RS}$ is low. Following reset, the clock generation mode can be reconfigured by writing to the internal clock mode register in software.
X2/CLKIN[2]	I	Clock/oscillator input. If the internal oscillator is not being used, X2/CLKIN functions as the clock input. (This is revision depended, see Section 3.6 for additional information.)
X1	O	Output pin from the internal oscillator for the crystal. If the internal oscillator is not used, X1 should be left unconnected. X1 does not go into the high-impedance state when $\overline{OFF}$ is low. (This is revision depended, see Section 3.6 for additional information.)

Table 2-2. Signal Descriptions (continued)

TERMINAL NAME	I/O(1)	DESCRIPTION
TOUT	O/Z	Timer output. TOUT signals a pulse when the on-chip timer counts down past zero. The pulse is one CLKOUT cycle wide. TOUT also goes into the high-impedance state when $\overline{OFF}$ is low.
MULTICHANNEL BUFFERED SERIAL PORT 0 (McBSP #0), MULTICHANNEL BUFFERED SERIAL PORT 1 (McBSP #1), AND MULTICHANNEL BUFFERED SERIAL PORT 2 (McBSP #2) SIGNALS		
BCLKR0(2) BCLKR1(2) BCLKR2(2)	I/O/Z	Receive clock input. BCLKR can be configured as an input or an output; it is configured as an input following reset. BCLKR serves as the serial shift clock for the buffered serial port receiver.
BDR0 BDR1 BDR2	I	Serial data receive input
BFSR0 BFSR1 BFSR2	I/O/Z	Frame synchronization pulse for receive input. BFSR can be configured as an input or an output; it is configured as an input following reset. The BFSR pulse initiates the receive data process over BDR.
BCLKX0(2) BCLKX1(2) BCLKX2(2)	I/O/Z	Transmit clock. BCLKX serves as the serial shift clock for the McBSP transmitter. BCLKX can be configured as an input or an output, and is configured as an input following reset. BCLKX enters the high-impedance state when $\overline{OFF}$ goes low.
BDX0 BDX1 BDX2	O/Z	Serial data transmit output. BDX is placed in the high-impedance state when not transmitting, when $\overline{RS}$ is asserted, or when $\overline{OFF}$ is low.
HOST-PORT INTERFACE SIGNALS		
BFSX0 BFSX1 BFSX2	I/O/Z	Frame synchronization pulse for transmit input/output. The BFSX pulse initiates the data transmit process over BDX. BFSX can be configured as an input or an output, and is configured as an input following reset. BFSX goes into the high-impedance state when $\overline{OFF}$ is low.
HD0-HD7(2)(3)	I/O/Z	Parallel bidirectional data bus. The HPI data bus is used by a host device bus to exchange information with the HPI registers. These pins can also be used as general-purpose I/O pins. HD0-HD7 is placed in the high-impedance state when not outputting data or when $\overline{OFF}$ is low. The HPI data bus includes bus holders to reduce the static power dissipation caused by floating, unused pins. When the HPI data bus is not being driven by the 5410A, the bus holders keep the pins at the previous logic level. The HPI data bus holders are disabled at reset and can be enabled/disabled via the HBH bit of the BSCR. These pins also have Schmitt trigger inputs.
HCNTL0(4) HCNTL1(4)	I	Control inputs. HCNTL0 and HCNTL1 select a host access to one of the three HPI registers. The control inputs have internal pullups that are only enabled when HPIENA = 0. These pins are not used when HPI16 = 1.
HBIL(4)	I	Byte identification. HBIL identifies the first or second byte of transfer. The HPIL input has an internal pullup resistor that is only enabled when HPIENA = 0. This pin is not used when HPI16 = 1.
$\overline{HCS}$(2)(4)	I	Chip select. $\overline{HCS}$ is the select input for the HPI and must be driven low during accesses. The chip select input has an internal pullup resistor that is only enabled when HPIENA = 0.
$\overline{HDS1}$ (2) (4) $\overline{HDS2}$ (2) (4)	I	Data strobe. $\overline{HDS1}$ and $\overline{HDS2}$ are driven by the host read and write strobes to control the transfer. The strobe inputs have internal pullup resistors that are only enabled when HPIENA = 0.
$\overline{HAS}$(2)(4)	I	Address strobe. Host with multiplexed address and data pins requires $\overline{HAS}$ to latch the address in the HPIA register. $\overline{HAS}$ input has an internal pullup resistor that is only enabled when HPIENA = 0.
HR/$\overline{W}$(4)	I	Read/write. HR/$\overline{W}$ controls the direction of the HPI transfer. HR/$\overline{W}$ has an internal pullup resistor that is only enabled when HPIENA = 0.
HRDY	O/Z	Ready output. HRDY goes into the high-impedance state when $\overline{OFF}$ is low. The ready output informs the host when the HPI is ready for the next transfer.
$\overline{HINT}$	O/Z	Interrupt output. This output is used to interrupt the host. When the DSP is in reset, $\overline{HINT}$ is driven high. $\overline{HINT}$ goes into the high-impedance state when $\overline{OFF}$ is low. This pin is not used when HPI16 = 1.
HPIENA(5)	I	HPI module select. HPIENA must be tied to DV_{DD} to have HPI selected. If HPIENA is left open or connected to ground, the HPI module is not selected, internal pullup for the HPI input pins are enabled, and the HPI data bus has holders set. HPIENA is provided with an internal pulldown resistor that is always active. HPIENA is sampled when $\overline{RS}$ goes high and is ignored until $\overline{RS}$ goes low again.
HPI16(5)	I	HPI16 mode selection. This pin must be tied to DV_{DD} to enable HPI16 mode. The pin has an internal pulldown resistor which is always active. If HPI16 is left open or driven low, the HPI16 mode is disabled.
SUPPLY PINS		
CV_{SS}	S	Ground. Dedicated ground for the core CPU

(4) This pin has an internal pullup resistor.
(5) This pin has an internal pulldown resistor.

Table 2-2. Signal Descriptions (continued)

TERMINAL NAME	I/O(1)	DESCRIPTION
CV_{DD}	S	$+V_{DD}$. Dedicated power supply for the core CPU
DV_{SS}	S	Ground. Dedicated ground for I/O pins
DV_{DD}	S	$+V_{DD}$. Dedicated power supply for I/O pins
TEST PINS		
TCK(2)(4)	I	IEEE standard 1149.1 test clock. TCK is normally a free-running clock signal with a 50% duty cycle. The changes on test access port (TAP) of input signals TMS and TDI are clocked into the TAP controller, instruction register, or selected test data register on the rising edge of TCK. Changes at the TAP output signal (TDO) occur on the falling edge of TCK.
TDI(4)	I	IEEE standard 1149.1 test data input. Pin with internal pullup device. TDI is clocked into the selected register (instruction or data) on a rising edge of TCK.
TDO	O/Z	IEEE standard 1149.1 test data output. The contents of the selected register (instruction or data) are shifted out of TDO on the falling edge of TCK. TDO is in the high-impedance state except when the scanning of data is in progress. TDO also goes into the high-impedance state when $\overline{OFF}$ is low.
TMS(4)	I	IEEE standard 1149.1 test mode select. Pin with internal pullup device. This serial control input is clocked into the TAP controller on the rising edge of TCK.
$\overline{TRST}$ (5) (6)	I	IEEE standard 1149.1 test reset. $\overline{TRST}$, when high, gives the IEEE standard 1149.1 scan system control of the operations of the device. If $\overline{TRST}$ is driven low, the device operates in its functional mode, and the IEEE standard 1149.1 signals are ignored. Pin with internal pulldown device.
EMU0(7)	I/O/Z	Emulator 0 pin. When $\overline{TRST}$ is driven low, EMU0 must be high for activation of the $\overline{OFF}$ condition. When $\overline{TRST}$ is driven high, EMU0 is used as an interrupt to or from the emulator system and is defined as input/output by way of the IEEE standard 1149.1 scan system.
EMU1/$\overline{OFF}$(7)	I/O/Z	Emulator 1 pin/disable all outputs. When $\overline{TRST}$ is driven high, EMU1/$\overline{OFF}$ is used as an interrupt to or from the emulator system and is defined as input/output by way of IEEE standard 1149.1 scan system. When $\overline{TRST}$ is driven low, EMU1/$\overline{OFF}$ is configured as $\overline{OFF}$. The EMU1/$\overline{OFF}$ signal, when active low, puts all output drivers into the high-impedance state. Note that $\overline{OFF}$ is used exclusively for testing and emulation purposes (not for multiprocessing applications). Therefore, for the $\overline{OFF}$ condition, the following apply: • $\overline{TRST}$= low, • EMU0 = high • EMU1/$\overline{OFF}$= low

(6) Although this pin includes an internal pulldown resistor, a 470-Ω external pulldown is required. If the $\overline{TRST}$ pin is connected to multiple DSPs, a buffer is recommended to ensure the V_{IL} and V_{IH} specifications are met.
(7) This pin must be pulled up with a 4.7-kΩ resistor to ensure the device is operable in functional mode or emulation mode.

3 Functional Overview

The following functional overview is based on the block diagram in Figure 3-1.

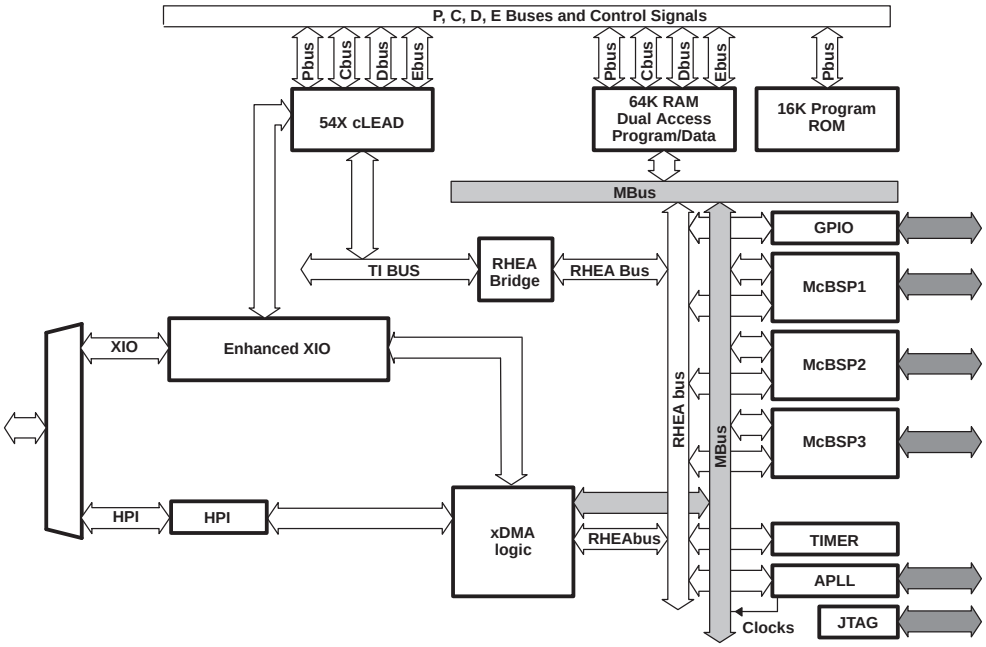


Figure 3-1. TMS320VC5410A Functional Block Diagram

3.1 Memory

The 5410A device provides both on-chip ROM and RAM memories to aid in system performance and integration.

3.1.1 Data Memory

The data memory space addresses up to 64K of 16-bit words. The device automatically accesses the on-chip RAM when addressing within its bounds. When an address is generated outside the RAM bounds, the device automatically generates an external access.

The advantages of operating from on-chip memory are as follows:

- Higher performance because no wait states are required
- Higher performance because of better flow within the pipeline of the central arithmetic logic unit (CALU)
- Lower cost than external memory
- Lower power than external memory

The advantage of operating from off-chip memory is the ability to access a larger address space.

3.1.2 Program Memory

Software can configure their memory cells to reside inside or outside of the program address map. When the cells are mapped into program space, the device automatically accesses them when their addresses are within bounds. When the program-address generation (PAGEN) logic generates an address outside its bounds, the device automatically generates an external access. The advantages of operating from on-chip memory are as follows:

- Higher performance because no wait states are required
- Lower cost than external memory
- Lower power than external memory

The advantage of operating from off-chip memory is the ability to access a larger address space.

3.1.3 Extended Program Memory

The 5410A uses a paged extended memory scheme in program space to allow access of up to 8192K of program memory. In order to implement this scheme, the 5410A includes several features which are also present on C548/549/5410:

- Twenty-three address lines, instead of sixteen
- An extra memory-mapped register, the XPC
- Six extra instructions for addressing extended program space

Program memory in the 5410A is organized into 128 pages that are each 64K in length.

The value of the XPC register defines the page selection. This register is memory-mapped into data space to address 001Eh. At a hardware reset, the XPC is initialized to 0.

3.1.4 On-Chip ROM With Bootloader

The 5410A features a 16K-word $\times$ 16-bit on-chip maskable ROM that can only be mapped into program memory space.

Customers can arrange to have the ROM of the 5410A programmed with contents unique to any particular application.

A bootloader is available in the standard 5410A on-chip ROM. This bootloader can be used to automatically transfer user code from an external source to anywhere in the program memory at power up. If MP/$\overline{\text{MC}}$ of the device is sampled low during a hardware reset, execution begins at location FF80h of the on-chip ROM. This location contains a branch instruction to the start of the bootloader program.

The standard 5410A devices provide different ways to download the code to accommodate various system requirements:

- Parallel from 8-bit or 16-bit-wide EPROM
- Parallel from I/O space, 8-bit or 16-bit mode
- Serial boot from serial ports, 8-bit or 16-bit mode
- Host-port interface boot
- Serial EEPROM mode
- Warm boot

The standard on-chip ROM layout is shown in Table 3-1.

Table 3-1. Standard On-Chip ROM Layout

ADDRESS RANGE	DESCRIPTION
C000h-D4FFh	ROM tables for the GSM EFR speech codec
D500h-F7FFh	Reserved
F800h-FBFFh	Bootloader
FC00h-FCFFh	μ-Law expansion table
FD00h-FDFFh	A-Law expansion table
FE00h-FEFFh	Sine look-up table
FF00h-FF7Fh	Reserved(1)
FF80h-FFFFh	Interrupt vector table

(1) In the 5410A ROM, 128 words are reserved for factory device-testing purposes. Application code to be implemented in on-chip ROM must reserve these 128 words at addresses FF00h-FF7Fh in program space.

3.1.5 On-Chip RAM

The 5410A device contains 64K-word × 16-bit of on-chip dual-access RAM (DARAM).

The DARAM is composed of eight blocks of 8K words each. Each block in the DARAM can support two reads in one cycle, or a read and a write in one cycle. Four blocks of DARAM are located in the address range 0080h-7FFFh in data space, and can be mapped into program/data space by setting the OVLY bit to one. The other four blocks of DARAM are located in the address range 18000h-1FFFFh in program space. The DARAM located in the address range 18000h-1FFFFh in program space can be mapped into data space by setting the DROM bit to one.

3.1.6 On-Chip Memory Security

The TMS320VC5410A device has a maskable option to protect the contents of on-chip memories.

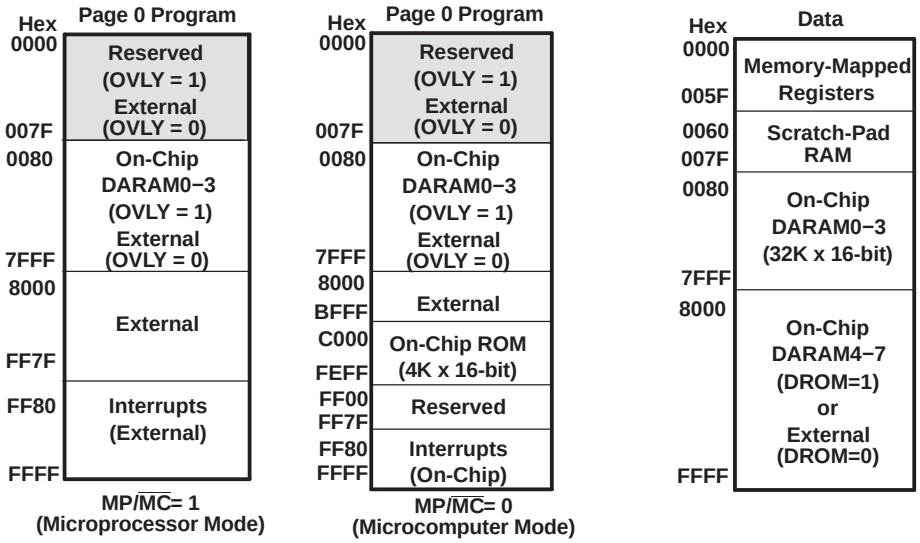
When the *RAM/ROM* security option is selected, the following restrictions apply:

- Only the on-chip ROM-originating instructions can read the contents of the on-chip ROM. On-chip RAM and external RAM-originating instructions cannot read data from ROM; instead, 0FFFFh is read. Code can still branch to ROM from on-chip RAM or external program memory.
- The contents of on-chip RAM can be read by all instructions, even by instructions fetched from external memory. To protect the internal RAM, the user must never branch to external memory.
- The security feature completely disables the scan-based emulation capability of the 54x to prevent the use of a debugger utility. This only affects emulation and does not prevent the use of the JTAG boundary scan test capability.
- The device is internally forced into microcomputer mode at reset (MP/$\overline{MC}$ bit forced to zero), preventing the ROM from being disabled by the external MP/$\overline{MC}$ pin. The status of the MP/$\overline{MC}$ bit in the PMST register can be changed after reset by the user application.
- HPI writes have no restriction, but HPI reads are restricted to the 4000h - 5FFFh address range.

If the *ROM*-only security option is selected the following restrictions apply:

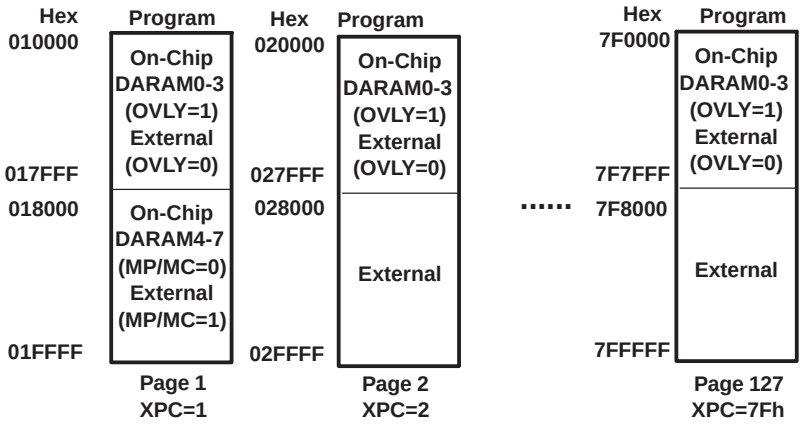
- Only the on-chip ROM-originating instructions can read the contents of the on-chip ROM. On-chip RAM and external RAM-originating instruction cannot read data from ROM; instead, 0FFFFh is read. Code can still branch to ROM from on-chip RAM or external program memory.
- The contents of on-chip RAM can be read by all instructions, even by instructions fetched from external memory. To protect the internal RAM the user must never branch to external memory.
- The security feature completely disables the scan-based emulation capability of the 54x to prevent the use of a debugger utility. This only affects emulation and does not prevent the use of the JTAG boundary scan test capability.
- The device can be started in either microcomputer mode or microprocessor mode at reset (depends on the MP/$\overline{MC}$ pin).
- HPI reads and writes have no restriction.

3.1.7 Memory Map



A. Address ranges for on-chip DARAM in data memory are: DARAM0: 0080h-1FFFh; DARAM1: 2000h-3FFFh DARAM2: 4000h-5FFFh; DARAM3: 6000h-7FFFh DARAM4: 8000h-9FFFh; DARAM5: A000h-BFFFh DARAM6: C000h-DFFFh; DARAM7: E000h-FFFFh

Figure 3-2. Program and Data Memory Map



A. Address ranges for on-chip DARAM in program memory are: DARAM4: 018000h-019FFFh; DARAM5: 01A000h-01 BFFFh DARAM6: 01C000h-01DFFFh; DARAM7: 01E000h-01FFFFh

Figure 3-3. Extended Program Memory Map

3.1.7.1 Relocatable Interrupt Vector Table

The reset, interrupt, and trap vectors are addressed in program space. These vectors are soft — meaning that the processor, when taking the trap, loads the program counter (PC) with the trap address and executes the code at the vector location. Four words, either two 1-word instructions or one 2-word instruction, are reserved at each vector location to accommodate a delayed branch instruction which allows branching to the appropriate interrupt service routine without the overhead.

At device reset, the reset, interrupt, and trap vectors are mapped to address FF80h in program space. However, these vectors can be remapped to the beginning of any 128-word page in program space after device reset. This is done by loading the interrupt vector pointer (IPTR) bits in the PMST register with the appropriate 128-word page boundary address. After loading IPTR, any user interrupt or trap vector is mapped to the new 128-word page.

NOTE

The hardware reset ($\overline{RS}$) vector cannot be remapped because the hardware reset loads the IPTR with 1s. Therefore, the reset vector is always fetched at location FF80h in program space.

15	14	13	12	11	10	9	8

	R/W-MP/$\overline{MC}$ pin	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0

LEGEND: R = Read, W = Write, n = value at reset

Figure 3-4. Processor Mode Status Register (PMST)

Table 3-2. Processor Mode Status Register (PMST) Field Descriptions

BIT	FIELD	VALUE	DESCRIPTION
15-7	IPTR	1FFh	Interrupt vector pointer. The 9-bit IPTR field points to the 128-word program page where the interrupt vectors reside. The interrupt vectors can be remapped to RAM for boot-loaded operations. At reset, these bits are all set to 1; the reset vector always resides at address FF80h in program memory space. The RESET instruction does not affect this field.
6	MP/$\overline{MC}$	MP/$\overline{MC}$ pin	Microprocessor/microcomputer mode. MP/$\overline{MC}$ enables/disables the on-chip ROM to be addressable in program memory space.
		0	The on-chip ROM is enabled and addressable.
		1	The on-chip ROM is not available.
			MP/$\overline{MC}$ is set to the value corresponding to the logic level on the MP/$\overline{MC}$ pin when sampled at reset. This pin is not sampled again until the next reset. The RESET instruction does not affect this bit. This bit can also be set or cleared by software.
5	OVLY		RAM overlay. OVLY enables on-chip dual-access data RAM blocks to be mapped into program space. The values for the OVLY bit are:
		0	The on-chip RAM is addressable in data space but not in program space.
		1	The on-chip RAM is mapped into program space and data space. Data page 0 (addresses 0h to 7Fh), however, is not mapped into program space.
4	AVIS		Address visibility mode. AVIS enables/disables the internal program address to be visible at the address pins.
		0	The external address lines do not change with the internal program address. Control and data lines are not affected and the address bus is driven with the last address on the bus.
		1	This mode allows the internal program address to appear at the pins of the 5410A so that the internal program address can be traced. Also, it allows the interrupt vector to be decoded in conjunction with $\overline{IACK}$ when the interrupt vectors reside on on-chip memory.
3	DROM		Data ROM. DROM enables on-chip ROM to be mapped into data space. The values for the DROM bit are:
		0	The on-chip ROM is not mapped into data space.
		1	A portion of the on-chip RAM is mapped into data space.
2	CLKOFF	0	CLOCKOUT off. When the CLKOFF bit is 1, the output of CLKOUT is disabled and remains at a high level.
1	SMUL	0	Saturation on multiplication. When SMUL = 1, saturation of a multiplication result occurs before performing the accumulation in a MAC of MAS instruction. The SMUL bit applies only when OVM = 1 and FRCT = 1.
0	SST	0	Saturation on store. When SST = 1, saturation of the data from the accumulator is enabled before storing in memory. The saturation is performed after the shift operation.

3.2 On-Chip Peripherals

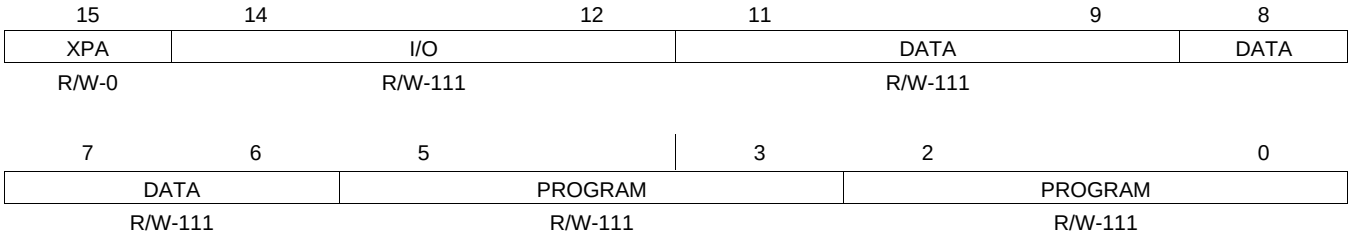
The 5410A device has the following peripherals:

- Software-programmable wait-state generator
- Programmable bank-switching
- A host-port interface (HPI8/16)
- Three multichannel buffered serial ports (McBSPs)
- A hardware timer
- A clock generator with a multiple phase-locked loop (PLL)
- Enhanced external parallel interface (XIO2)
- A DMA controller (DMA)

3.2.1 Software-Programmable Wait-State Generator

The software wait-state generator of the 5410A can extend external bus cycles by up to fourteen machine cycles. Devices that require more than fourteen wait states can be interfaced using the hardware READY line. When all external accesses are configured for zero wait states, the internal clocks to the wait-state generator are automatically disabled. Disabling the wait-state generator clocks reduces the power consumption of the 5410A.

The software wait-state register (SWWSR) controls the operation of the wait-state generator. The 14 LSBs of the SWWSR specify the number of wait states (0 to 7) to be inserted for external memory accesses to five separate address ranges. This allows a different number of wait states for each of the five address ranges. Additionally, the software wait-state multiplier (SWSM) bit of the software wait-state control register (SWCR) defines a multiplication factor of 1 or 2 for the number of wait states. At reset, the wait-state generator is initialized to provide seven wait states on all external memory accesses. The SWWSR bit fields are shown in Figure 3-5 and described in Table 3-3.



LEGEND: R = Read, W = Write, n = value at reset

Figure 3-5. Software Wait-State Register (SWWSR) [Memory-Mapped Register (MMR) Address 0028h]

Table 3-3. Software Wait-State Register (SWWSR) Field Descriptions

BIT	FIELD	VALUE	DESCRIPTION
15	XPA	0	Extended program address control bit. XPA is used in conjunction with the program space fields (bits 0 through 5) to select the address range for program space wait states.
14-12	I/O	111	I/O space. The field value (0-7) corresponds to the base number of wait states for I/O space accesses within addresses 0000-FFFFh. The SWSM bit of the SWCR defines a multiplication factor of 1 or 2 for the base number of wait states.
11-9	Data	111	Upper data space. The field value (0-7) corresponds to the base number of wait states for external data space accesses within addresses 8000-FFFFh. The SWSM bit of the SWCR defines a multiplication factor of 1 or 2 for the base number of wait states.
8-6	Data	111	Lower data space. The field value (0-7) corresponds to the base number of wait states for external data space accesses within addresses 0000-7FFFh. The SWSM bit of the SWCR defines a multiplication factor of 1 or 2 for the base number of wait states.
5-3	Program	111	Upper program space. The field value (0-7) corresponds to the base number of wait states for external program space accesses within the following addresses: • XPA = 0: xx8000 - xxFFFFh • XPA = 1: 400000h - 7FFFFFh The SWSM bit of the SWCR defines a multiplication factor of 1 or 2 for the base number of wait states.
2-0	Program	111	Program space. The field value (0-7) corresponds to the base number of wait states for external program space accesses within the following addresses: • XPA = 0: xx0000 - xx7FFFh • XPA = 1: 000000 - 3FFFFFh The SWSM bit of the SWCR defines a multiplication factor of 1 or 2 for the base number of wait states.

The software wait-state multiplier bit of the software wait-state control register (SWCR) is used to extend the base number of wait states selected by the SWWSR. The SWCR bit fields are shown in Figure 3-6 and described in Table 3-4.

Table 3-4. Software Wait-State Control Register (SWCR) Field Descriptions

BIT	FIELD	VALUE	FUNCTION
15-1	Reserved	0	These bits are reserved and are unaffected by writes.
0	SWSM		Software wait-state multiplier. Used to multiply the number of wait states defined in the SWWSR by a factor of 1 or 2.
		0	Wait-state base values are unchanged (multiplied by 1).
		1	Wait-state base values are multiplied by 2 for a maximum of 14 wait states.

3.2.2 Programmable Bank-Switching

Programmable bank-switching logic allows the 5410A to switch between external memory banks without requiring external wait states for memories that need additional time to turn off. The bank-switching logic automatically inserts one cycle when accesses cross a 32K-word memory-bank boundary inside program or data space.

Bank-switching is defined by the bank-switching control register (BSCR), which is memory-mapped at address 0029h. The bit fields of the BSCR are shown in Figure 3-7 and are described in Table 3-5.

Figure 3-7. Bank-Switching Control Register (BSCR) [MMR Address 0029h]

Table 3-5. Bank-Switching Control Register (BSCR) Field Descriptions

BIT	FIELD	VALUE	DESCRIPTION
15	$\overline{\text{CONSEC}}$(1)		Consecutive bank-switching**.** Specifies the bank-switching mode.
		0	Bank-switching on 32K bank boundaries only. This bit is cleared if fast access is desired for continuous memory reads (i.e., no starting and trailing cycles between read cycles).
		1	Consecutive bank switches on external memory reads. Each read cycle consists of 3 cycles: starting cycle, read cycle, and trailing cycle.
14-13	DIVFCT		CLKOUT output divide factor**.** The CLKOUT output is driven by an on-chip source having a frequency equal to 1/(DIVFCT+1) of the DSP clock.
		00	CLKOUT is not divided.
		01	CLKOUT is divided by 2 from the DSP clock.
		10	CLKOUT is divided by 3 from the DSP clock.
		11	CLKOUT is divided by 4 from the DSP clock (default value following reset.
12	IACKOFF		$\overline{\text{IACK}}$ signal output off**.** Controls the output of the $\overline{\text{IACK}}$ signal. IACKOFF is set to 1 at reset.
		0	The $\overline{\text{IACK}}$ signal output off function is disabled.
		1	The $\overline{\text{IACK}}$ signal output off function is enabled.
11-3	Reserved		Reserved
2	HBH		HPI bus holder. Controls the HPI bus holder. HBH is cleared to 0 at reset.
		0	The bus holder is disabled except when HPI16=1.
		1	The bus holder is enabled. When not driven, the HPI data bus, HD[7:0] is held in the previous logic level.
1	BH		Bus holder. Controls the bus holder. BH is cleared to 0 at reset.
		0	The bus holder is disabled.
		1	The bus holder is enabled. When not driven, the data bus, D[15:0] is held in the previous logic level.
0	Reserved		Reserved

(1) For additional information, see Section 3.7 of this document.

The 5410A has an internal register that holds the MSB of the last address used for a read or write operation in program or data space. In the non-consecutive bank switches ($\overline{\text{CONSEC}}$ = 0), if the MSB of the address used for the current read does not match that contained in this internal register, the $\overline{\text{MSTRB}}$ (memory strobe) signal is not asserted for one CLKOUT cycle. During this extra cycle, the address bus switches to the new address. The contents of the internal register are replaced with the MSB for the read of the current address. If the MSB of the address used for the current read matches the bits in the register, a normal read cycle occurs.

In non-consecutive bank switches ($\overline{\text{CONSEC}}$ = 0), if repeated reads are performed from the same memory bank, no extra cycles are inserted. When a read is performed from a different memory bank, memory conflicts are avoided by inserting an extra cycle. For more information, see Section 3.7 of this document.

The bank-switching mechanism automatically inserts one extra cycle in the following cases:

- A memory read followed by another memory read from a different memory bank.
- A program-memory read followed by a data-memory read.
- A data-memory read followed by a program-memory read.
- A program-memory read followed by another program-memory read from a different page.

3.2.3 Bus Holders

The 5410A has two bus holder control bits, BH (BSCR[1]) and HBH (BSCR[2]), to control the bus keepers of the address bus (A[16-0]), data bus (D[15-0]), and the HPI data bus (HD[7-0]). Bus keeper enabling/disabling is described in Table 3-6.

Table 3-6. Bus Holder Control Bits

HPI16 PIN	BH	HBH	D[15-0]	A[16-0]	HD[7-0]
0	0	0	OFF	OFF	OFF
0	0	1	OFF	OFF	ON
0	1	0	ON	OFF	OFF
0	1	1	ON	OFF	ON
1	0	0	OFF	OFF	ON
1	0	1	OFF	ON	ON
1	1	0	ON	OFF	ON
1	1	1	ON	ON	ON

3.3 Parallel I/O Ports

The 5410A has a total of 64K I/O ports. These ports can be addressed by the PORTR instruction or the PORTW instruction. The $\overline{IS}$ signal indicates a read/write operation through an I/O port. The 5410A can interface easily with external devices through the I/O ports while requiring minimal off-chip address-decoding circuits.

3.3.1 Enhanced 8-/16-Bit Host-Port Interface (HPI8/16)

The 5410A host-port interface, also referred to as the HPI8/16, is an enhanced version of the standard 8-bit HPI found on earlier TMS320C54x™ DSPs (542, 545, 548, and 549). The 5410A HPI can be used to interface to an 8-bit or 16-bit host. When the address and data buses for external I/O is not used (to interface to external devices in program/data/IO spaces), the 5410A HPI can be configured as an HPI16 to interface to a 16-bit host. This configuration can be accomplished by connecting the HPI16 pin to logic "1".

When the HPI16 pin is connected to a logic "0", the 5410A HPI is configured as an HPI8. The HPI8 is an 8-bit parallel port for interprocessor communication. The features of the HPI8 include:

Standard features:

- Sequential transfers (with autoincrement) or random-access transfers
- Host interrupt and C54x™ interrupt capability
- Multiple data strobes and control pins for interface flexibility

The HPI8 interface consists of an 8-bit bidirectional data bus and various control signals. Sixteen-bit transfers are accomplished in two parts with the HBIL input designating high or low byte. The host communicates with the HPI8 through three dedicated registers — the HPI address register (HPIA), the HPI data register (HPID), and the HPI control register (HPIC). The HPIA and HPID registers are only accessible by the host, and the HPIC register is accessible by both the host and the 5410A.

Enhanced features:

- Access to entire on-chip RAM through DMA bus
- Capability to continue transferring during emulation stop

The HPI16 is an enhanced 16-bit version of the TMS320C54x™ DSP 8-bit host-port interface (HPI8). The HPI16 is designed to allow a 16-bit host to access the DSP on-chip memory, with the host acting as the master of the interface. Some of the features of the HPI16 include:

- 16-bit bidirectional data bus
- Multiple data strobes and control signals to allow glueless interfacing to a variety of hosts
- Only nonmultiplexed address/data modes are supported
- 17-bit address bus used in nonmultiplexed mode to allow access to all internal memory (including internal extended address pages)
- HRDY signal to hold off host accesses due to DMA latency
- The HPI16 acts as a slave to a 16-bit host processor and allows access to the on-chip memory of the DSP.

NOTE

Only the nonmultiplexed mode is supported when the 5410A HPI is configured as a HPI16 (see Figure 3-8).

The 5410A HPI functions as a slave and enables the host processor to access the on-chip memory. A major enhancement to the 5410A HPI over previous versions is that it allows host access to the entire on-chip memory range of the DSP. The host and the DSP both have access to the on-chip RAM at all times and host accesses are always synchronized to the DSP clock. If the host and the DSP contend for access to the same location, the host has priority, and the DSP waits for one cycle. Note that since host accesses are always synchronized to the 5410A clock, an active input clock (CLKIN) is required for HPI accesses during IDLE states, and host accesses are not allowed while the 5410A reset pin is asserted.

3.3.2 HPI Nonmultiplexed Mode

In *nonmultiplexed* mode, a host with separate address/data buses can access the HPI16 data register (HPID) via the HD 16-bit bidirectional data bus, and the address register (HPIA) via the 17-bit HA address bus. The host initiates the access with the strobe signals ($\overline{HDS1}$, $\overline{HDS2}$, $\overline{HCS}$) and controls the direction of the access with the HR/$\overline{W}$ signal. The HPI16 can stall host accesses via the HRDY signal. Note that the HPIC register is not available in *nonmultiplexed* mode since there are no HCNTL signals available. All host accesses initiate a DMA read or write access. Figure 3-8 shows a block diagram of the HPI16 in *nonmultiplexed* mode.

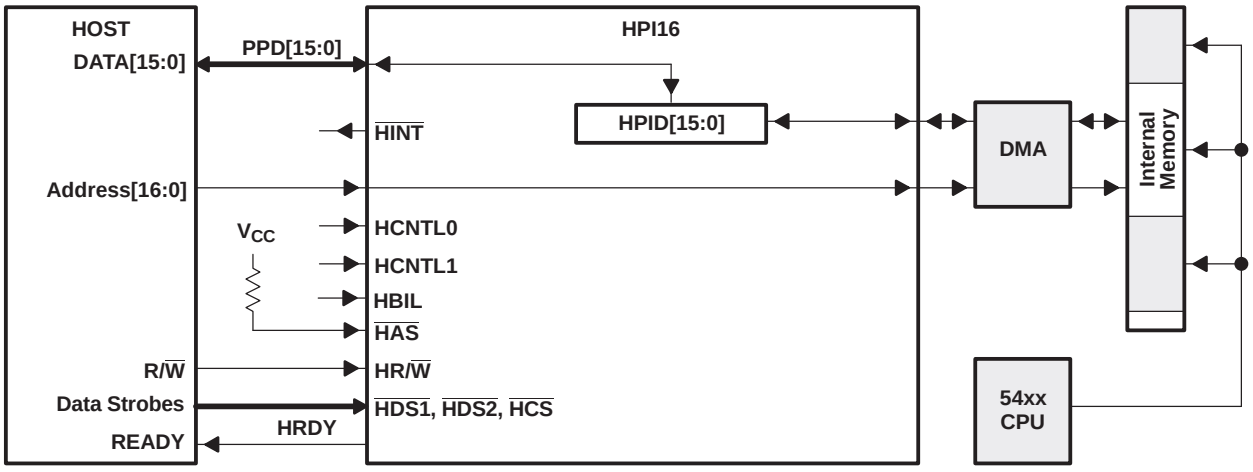

Figure 3-8. Host-Port Interface — Nonmultiplexed Mode

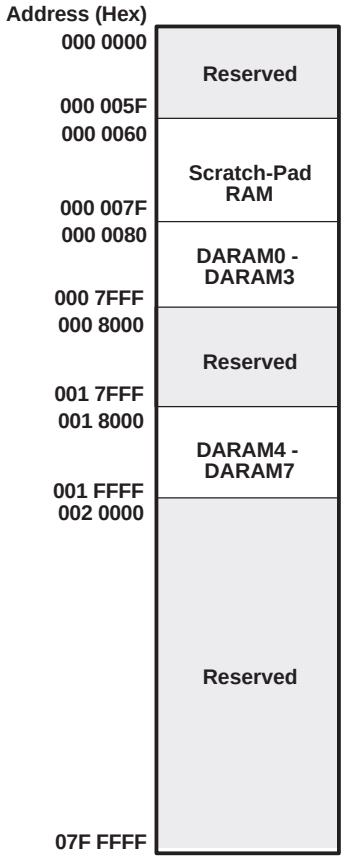

Figure 3-9. HPI Memory Map

3.4 Multichannel Buffered Serial Ports (McBSPs)

The 5410A device provides high-speed, full-duplex serial ports that allow direct interface to other C54x/LC54x devices, codecs, and other devices in a system. There are three multichannel buffered serial ports (McBSPs) on board (three per subsystem).

The McBSP provides:

- Full-duplex communication
- Double-buffer data registers, which allow a continuous data stream
- Independent framing and clocking for receive and transmit

In addition, the McBSP has the following capabilities:

- Direct interface to:
  - T1/E1 framers
  - MVIP switching-compatible and ST-BUS compliant devices
  - IOM-2 compliant device
  - AC97-compliant device
  - Serial peripheral interface (SPI)
- Multichannel transmit and receive of up to 128 channels
- A wide selection of data sizes, including: 8, 12, 16, 20, 24, or 32 bits
- μ-law and A-law companding
- Programmable polarity for both frame synchronization and data clocks
- Programmable internal clock and frame generation

The 5410A McBSPs have been enhanced to provide more flexibility in the choice of the sample rate generator input clock source. On previous TMS320C5000™ DSP platform devices, the McBSP sample rate input clock can be driven from one of two possible choices: the internal CPU clock, or the external CLKS pin. However, most C5000™ DSP devices have only the internal CPU clock as a possible source because the CLKS pin is not implemented on most device packages.

To accommodate applications that require an external reference clock for the sample rate generator, the 5410A McBSPs allow either the receive clock pin (BCLKR) or the transmit clock pin (BCLKX) to be configured as the input clock to the sample rate generator. This enhancement is enabled through two register bits: pin control register (PCR) bit 7 - enhanced sample clock mode (SCLKME), and sample rate generator register 2 (SRGR2) bit 13 - McBSP sample rate generator clock mode (CLKSM). SCLKME is an addition to the PCR contained in the McBSPs on previous C5000 devices. The new bit layout of the PCR is shown in Figure 3-10. For a description of the remaining bits, see *TMS320C54x DSP Reference Set, Volume 5: Enhanced Peripherals* (literature number SPRU302).

LEGEND: R = Read, W = Write, n = value at reset

Figure 3-10. Pin Control Register (PCR)

The selection of the sample rate generator (SRG) clock input source is made by the combination of the CLKSM and SCLKME bit values as shown in Table 3-7.

Table 3-7. Sample Rate Generator Clock Source Selection

SCLKME	CLKSM	SRG CLOCK SOURCE
0	0	CLKS (not available as a pin on 5410A)
0	1	CPU clock
1	0	BCLKR pin
1	1	BCLKX pin

When either of the bidirectional pins, BCLKR or BCLKX, is configured as the clock input, its output buffer is automatically disabled. For example, with SCLKME = 1 and CLKSM = 0, the BCLKR pin is configured as the SRG input. In this case, both the transmitter and receiver circuits can be synchronized to the SRG output by setting the PCR bits (9:8) for CLKXM = 1 and CLKRM = 1. However, the SRG output is only driven onto the BCLKX pin because the BCLKR output is automatically disabled.

The McBSP supports independent selection of multiple channels for the transmitter and receiver. When multiple channels are selected, each frame represents a time-division multiplexed (TDM) data stream. In using time-division multiplexed data streams, the CPU may only need to process a few of them. Thus, to save memory and bus bandwidth, multichannel selection allows independent enabling of particular channels for transmission and reception. Up to a maximum of 128 channels in a bit stream can be enabled or disabled.

The 5410A McBSPs have two working modes that are selected by setting the RMCME and XMCME bits in the multichannel control registers (MCR1x and MCR2x, respectively). See Figure 3-11 and Figure 3-12. For a description of the remaining bits, see *TMS320C54x DSP Reference Set, Volume 5: Enhanced Peripherals* (literature number SPRU302).

- In the first mode, when RMCME = 0 and XMCME = 0, there are two partitions (A and B), with each containing 16 channels as shown in Figure 3-11 and Figure 3-12. This is compatible with the McBSPs used in earlier TMS320C54x devices, where only 32-channel selection is enabled (default).

- In the second mode, with RMCME = 1 and XMCME = 1, the McBSPs have 128 channel selection capability. Twelve new registers (RCERCx-RCERHx and XCERCx-XCERHx) are used to enable the 128 channel selection. The subaddresses of the new registers are shown in Table 3-19. These new registers, functionally equivalent to the RCERA0-RCERB1 and XCERA0-XCERB1 registers in the 5420, are used to enable/disable the transmit and receive of additional channel partitions (C,D,E,F,G,

and H) in the128 channel stream. For example, XCERH1 is the transmit enable for channel partition H (channels 112 to 127) of MCBSP1 for each DSP subsystem. See Figure 3-13, Table 3-8, Figure 3-14, and Table 3-9 for bit layout and function of the receive and transmit registers .

		0	Disables transmit of *n*th channel in partition y.
		1	Enables transmit of *n*th channel in partition y.

The clock stop mode (CLKSTP) in the McBSP provides compatibility with the serial port interface (SPI) protocol. Clock stop mode works with only single-phase frames and one word per frame. The word sizes supported by the McBSP are programmable for 8-, 12-, 16-, 20-, 24-, or 32-bit operation. When the McBSP is configured to operate in SPI mode, both the transmitter and the receiver operate together as a master or as a slave.

The McBSP is fully static and operates at arbitrarily low clock frequencies. The maximum McBSP multichannel operating frequency on the 5410A is 9 MBps. Nonmultichannel operation is limited to 38 MBps.

3.5 Hardware Timer

The 5410A device features a 16-bit timing circuit with a 4-bit prescaler. The timer counter is decremented by one every CPU clock cycle. Each time the counter decrements to 0, a timer interrupt is generated. The timer can be stopped, restarted, reset, or disabled by specific status bits.

3.6 Clock Generator

The clock generator provides clocks to the 5410A device, and consists of a phase-locked loop (PLL) circuit. The clock generator requires a reference clock input, which can be provided from an external clock source. The reference clock input is then divided by two (DIV mode) to generate clocks for the 5410A device, or the PLL circuit can be used (PLL mode) to generate the device clock by multiplying the reference clock frequency by a scale factor, allowing use of a clock source with a lower frequency than that of the CPU. The PLL is an adaptive circuit that, once synchronized, locks onto and tracks an input clock signal.

When the PLL is initially started, it enters a transitional mode during which the PLL acquires lock with the input signal. Once the PLL is locked, it continues to track and maintain synchronization with the input signal. Then, other internal clock circuitry allows the synthesis of new clock frequencies for use as master clock for the 5410A device.

This clock generator allows system designers to select the clock source. The sources that drive the clock generator are:

- A crystal resonator circuit. The crystal resonator circuit is connected across the X1 and X2/CLKIN pins of the 5410A to enable the internal oscillator.
- An external clock. The external clock source is directly connected to the X2/CLKIN pin, and X1 is left unconnected.

NOTE

The crystal oscillator function is not supported by all die revisions of the 5410A device. See the *TMS320VC5410A Digital Signal Processor Silicon Errata* (literature number SPRZ187) to verify which die revisions support this functionality.

The software-programmable PLL features a high level of flexibility, and includes a clock scaler that provides various clock multiplier ratios, capability to directly enable and disable the PLL, and a PLL lock timer that can be used to delay switching to PLL clocking mode of the device until lock is achieved. Devices that have a built-in software-programmable PLL can be configured in one of two clock modes:

- PLL mode. The input clock (X2/CLKIN) is multiplied by 1 of 31 possible ratios.
- DIV (divider) mode. The input clock is divided by 2 or 4. Note that when DIV mode is used, the PLL can be completely disabled in order to minimize power dissipation.

The software-programmable PLL is controlled using the 16-bit memory-mapped (address 0058h) clock mode register (CLKMD). The CLKMD register is used to define the clock configuration of the PLL clock module. Note that upon reset, the CLKMD register is initialized with a predetermined value dependent only upon the state of the CLKMD1 - CLKMD3 pins. For more programming information, see the *TMS320C54x DSP Reference Set, Volume 1: CPU and Peripherals* (literature number SPRU131). The CLKMD pin configured clock options are shown in Table 3-10.

Table 3-10. Clock Mode Settings at Reset

CLKMD1	CLKMD2	CLKMD3	CLKMD RESET VALUE	CLOCK MODE(1)
0	0	0	0000h	(PLL and Oscillator disabled)
0	0	1	9007h	PLL x 10 (Oscillator enabled)
0	1	0	4007h	PLL x 5 (Oscillator enabled)
1	0	0	1007h	PLL x 2(Oscillator enabled)
1	1	0	F007h	PLL x 1 (Oscillator enabled)
1	1	1	0000h	(PLL disabled, Oscillator enabled)
1	0	1	F000h	1/4 (PLL disabled, Oscillator enabled)
0	1	1	—	Reserved (Bypass mode)

(1) The external CLKMD1-CLKMD3 pins are sampled to determine the desired clock generation mode while $\overline{RS}$ is low. Following reset, the clock generation mode can be reconfigured by writing to the internal clock mode register in software. However, the oscillator enable/disable selection is performed independently of the state of $\overline{RS}$; therefore, if CLKMD1-CLKMD3 are changed following reset, the oscillator enable/disable selection may change, but other aspects of the clock generation mode will not.

3.7 Enhanced External Parallel Interface (XIO2)

The 5410A external interface has been redesigned to include several improvements, including: simplification of the bus sequence, more immunity to bus contention when transitioning between read and write operations, the ability for external memory access to the DMA controller, and optimization of the power-down modes.

The bus sequence on the 5410A still maintains all of the same interface signals as on previous 54x devices, but the signal sequence has been simplified. Most external accesses now require 3 cycles composed of a leading cycle, an active (read or write) cycle, and a trailing cycle. The leading and trailing cycles provide additional immunity against bus contention when switching between read operations and write operations. To maintain high-speed read access, a consecutive read mode that performs single-cycle reads as on previous 54x devices is available.

Figure 3-15 shows the bus sequence for three cases: all I/O reads, memory reads in nonconsecutive mode, or single memory reads in consecutive mode. The accesses shown in Figure 3-15 always require 3 CLKOUT cycles to complete.

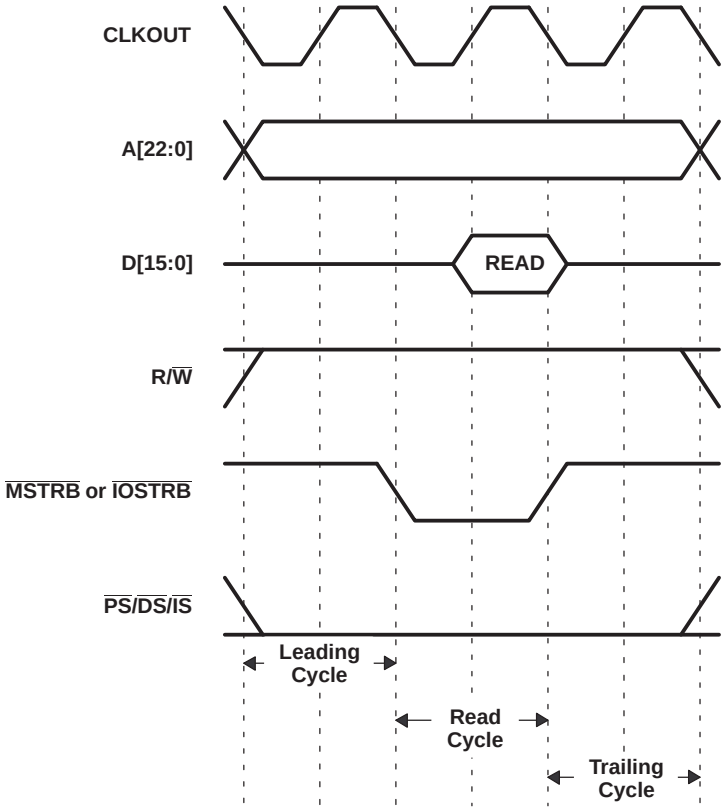

Figure 3-15. Nonconsecutive Memory Read and I/O Read Bus Sequence

Figure 3-16 shows the bus sequence for repeated memory reads in consecutive mode. The accesses shown in Figure 3-16 require (2+n) CLKOUT cycles to complete, where n is the number of consecutive reads performed.

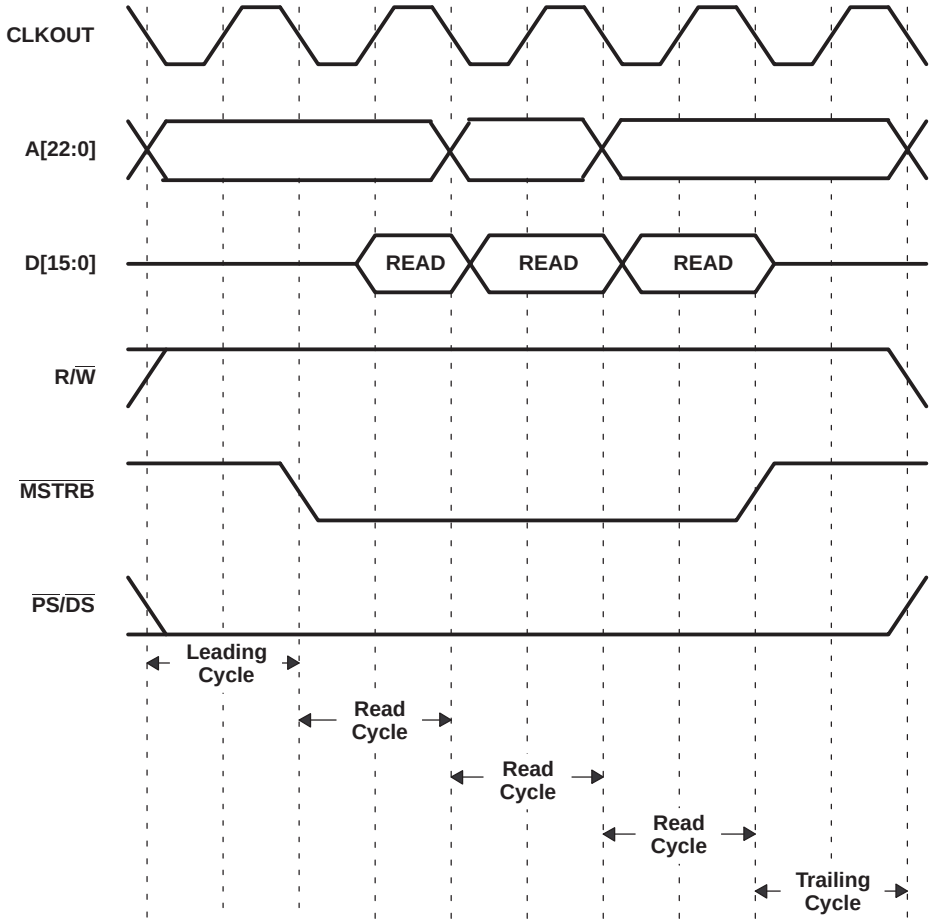

Figure 3-16. Consecutive Memory Read Bus Sequence (n = 3 reads)

Figure 3-17 shows the bus sequence for all memory writes and I/O writes. The accesses shown in Figure 3-17 always require three CLKOUT cycles to complete.

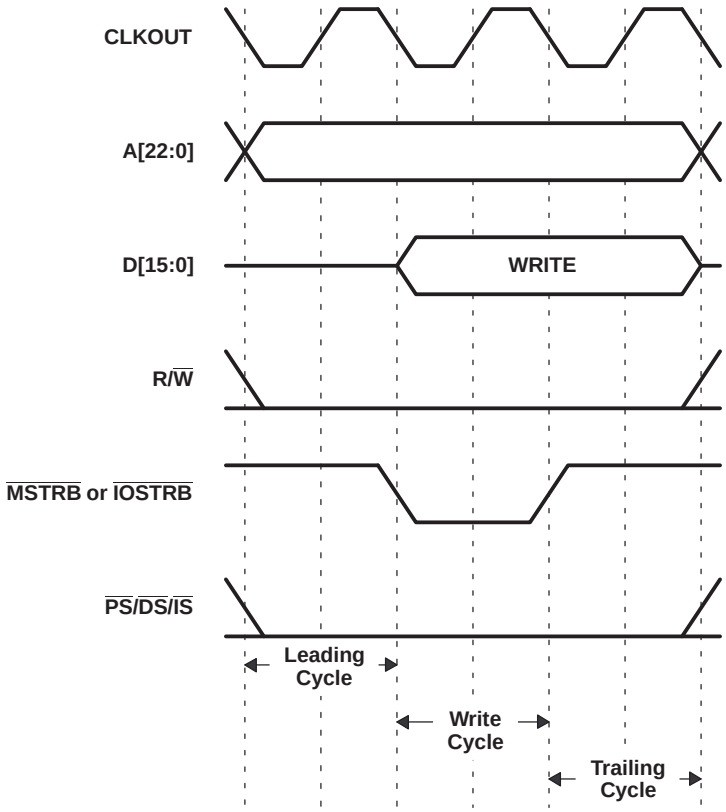

Figure 3-17. Memory Write and I/O Write Bus Sequence

The enhanced interface also provides the ability for DMA transfers to extend to external memory. For more information on DMA capability, see the DMA sections that follow.

The enhanced interface improves the low-power performance already present on the TMS320C5000™ DSP platform by switching off the internal clocks to the interface when it is not being used. This power-saving feature is automatic, requires no software setup, and causes no latency in the operation of the interface.

Additional features integrated in the enhanced interface are the ability to automatically insert bank-switching cycles when crossing 32K memory boundaries (see Section 3.2.2), the ability to program up to 14 wait states through software (see Section 3.2.1), and the ability to divide down CLKOUT by a factor of 1, 2, 3, or 4. Dividing down CLKOUT provides an alternative to wait states when interfacing to slower external memory or peripheral devices. While inserting wait states extends the bus sequence during read or write accesses, it does not slow down the bus signal sequences at the beginning and the end of the access. Dividing down CLKOUT provides a method of slowing the entire bus sequence when necessary. The CLKOUT divide-down factor is controlled through the DIVFCT field in the bank-switching control register (BSCR) (see Table 3-5).

3.8 DMA Controller

The 5410A direct memory access (DMA) controller transfers data between points in the memory map without intervention by the CPU. The DMA allows movements of data to and from internal program/data memory, internal peripherals (such as the McBSPs), or external memory devices to occur in the background of CPU operation. The DMA has six independent programmable channels, allowing six different contexts for DMA operation.

3.8.1 Features

The DMA has the following features:

- The DMA operates independently of the CPU.
- The DMA has six channels. The DMA can keep track of the contexts of six independent block transfers.
- The DMA has higher priority than the CPU for both internal and external accesses.
- Each channel has independently programmable priorities.
- Each channel's source and destination address registers can have configurable indexes through memory on each read and write transfer, respectively. The address may remain constant, be post-incremented, be post-decremented, or be adjusted by a programmable value.
- Each read or write internal transfer may be initialized by selected events.
- On completion of a half- or entire-block transfer, each DMA channel may send an interrupt to the CPU.
- The DMA can perform double-word internal transfers (a 32-bit transfer of two 16-bit words).

3.8.2 DMA External Access

The 5410A DMA supports external accesses to extended program, extended data, and extended I/O memory. These overlay pages are only visible to the DMA controller. A maximum of two DMA channels can be used for external memory accesses. The DMA external accesses require a minimum of 8 cycles for external writes and a minimum of 11 cycles for external reads assuming the XIO02 is in consecutive mode ($\overline{\text{CONSEC}}$ = 1), wait state is set to two, and CLKOUT is not divided (DIVFCT = 00).

The control of the bus is arbitrated between the CPU and the DMA While the DMA or CPU is in control of the external bus, the other will be held-off via wait states until the current transfer is complete. The DMA takes precedence over XIO requests.

- Only two channels are available for external accesses. (One for external reads and one for external writes.)
- Single-word (16-bit) transfers are supported for external accesses.
- The DMA does not support transfers from the peripherals to external memory.
- The DMA does not support transfers from external memory to the peripherals.
- The DMA does not support external-to-external transfers.
- The DMA does not support synchronized external transfers.

To allow the DMA access to extended data pages, the SLAXS and DLAXS bits are added to the DMMCRn register (see Figure 3-18).

15	14	13	12	11	10	8
AUTOINIT	DINM	IMOD	CTMOD	SLAXS	SIND	

7	6	5	4	2	1	0
DMS		DLAXS	DIND		DMD	

LEGEND: R = Read, W = Write, n = value at reset

Figure 3-18. DMA Transfer Mode Control Register (DMMCRn)

These new bit fields were created to allow the user to define the space-select for the DMA (internal/external). The functions of the DLAXS and SLAXS bits are as follows:

DLAXS(DMMCRn[5]) Destination
0 = No external access (default internal)
1 = External access

SLAXS(DMMCRn[11]) Source
0 = No external access (default internal)
1 = External access

Table 3-11 lists the DMD bit values and their corresponding destination space.

Table 3-11. DMD Section of the DMMCRn Register

DMD	DESTINATION SPACE
00	PS
01	DS
10	I/O
11	Reserved

For the CPU external access, software can configure the memory cells to reside inside or outside the program address map. When the cells are mapped into program space, the device automatically accesses them when their addresses are within bounds. When the address generation logic generates an address outside its bounds, the device automatically generates an external access.

3.8.3 DMPREC Issue

When updating the DE bits of the DMPREC register while one or more DMA channel transfers are in progress, it is possible for the write to the DMPREC to cause an additional transfer on one of the active channels.

The problem occurs when an active channel completes a transfer at the same time that the user updates the DMPREC register. When the transfer completes, the DMA logic attempts to clear the DE bit corresponding to the complete channel transfer, but the register is instead updated with the CPU write (usually an ORM instruction) which can set the bit and cause an additional transfer on the channel. See the *TMS320VC5410A Digital Signal Processor Silicon Errata* (literature number SPRZ187) for further clarification.

A hardware workaround has been implemented in revision A of the 5410A device. This solution consists of an additional memory mapped register, DMCECTL (DMA Channel Enable Control), at DMA subbank register address 0x003E, with the following characteristics:

15	14	8
SET/RESET	Reserved	
W-0	W-0	

7	6	5	4	3	2	1	0
Reserved		CH5	CH4	CH3	CH2	CH1	CH0
W-0		W-0	W-0	W-0	W-0	W-0	W-0

LEGEND: R = Read, W = Write, n = value at reset

Figure 3-19. DMA Channel Enable Control Register (DMCECTL)

Table 3-12. DMA Channel Enable Control Register (DMCECTL) Field Descriptions

BIT	FIELD	VALUE	DESCRIPTION
15	Set/Reset		Sets or clears individual DE bits of the DMPREC register according to the values of CH0-CH5.
		0	Clears the DE bits of the DMPREC register as specified by CH0-CH5.
		1	Sets the DE bits of the DMPREC register as specified by CH0-CH5.
14-6	Reserved	0	Reserved.
5-0	CH5-CH0		These bits are used in conjunction with the set/reset bit to write to the individual DE bits of the DMPREC register.
		0	Corresponding DE bit in the DMPREC register is unaffected by the Set/Reset bit.
		1	Corresponding bit in the DMPREC register is set or cleared depending on the state of Set/Reset.

Use this register to enable or disable DMA channels instead of writing to the DMPREC register. For example, to enable channels zero and five, write a value of 0x8021 to DMA subbank register address 0x03E. In this case only DE0 and DE5 of the DMPREC are set to 1. Or for another example, to disable channel one, write a value of 0x02 to DMA subbank address 0x03E. In this case only DE1 is cleared. Note that this is a write-only register.

3.8.4 DMA Memory Map

The DMA memory map, shown in Figure 3-20, allows the DMA transfer to be unaffected by the status of the MP/$\overline{MC}$, DROM, and OVLY bits.

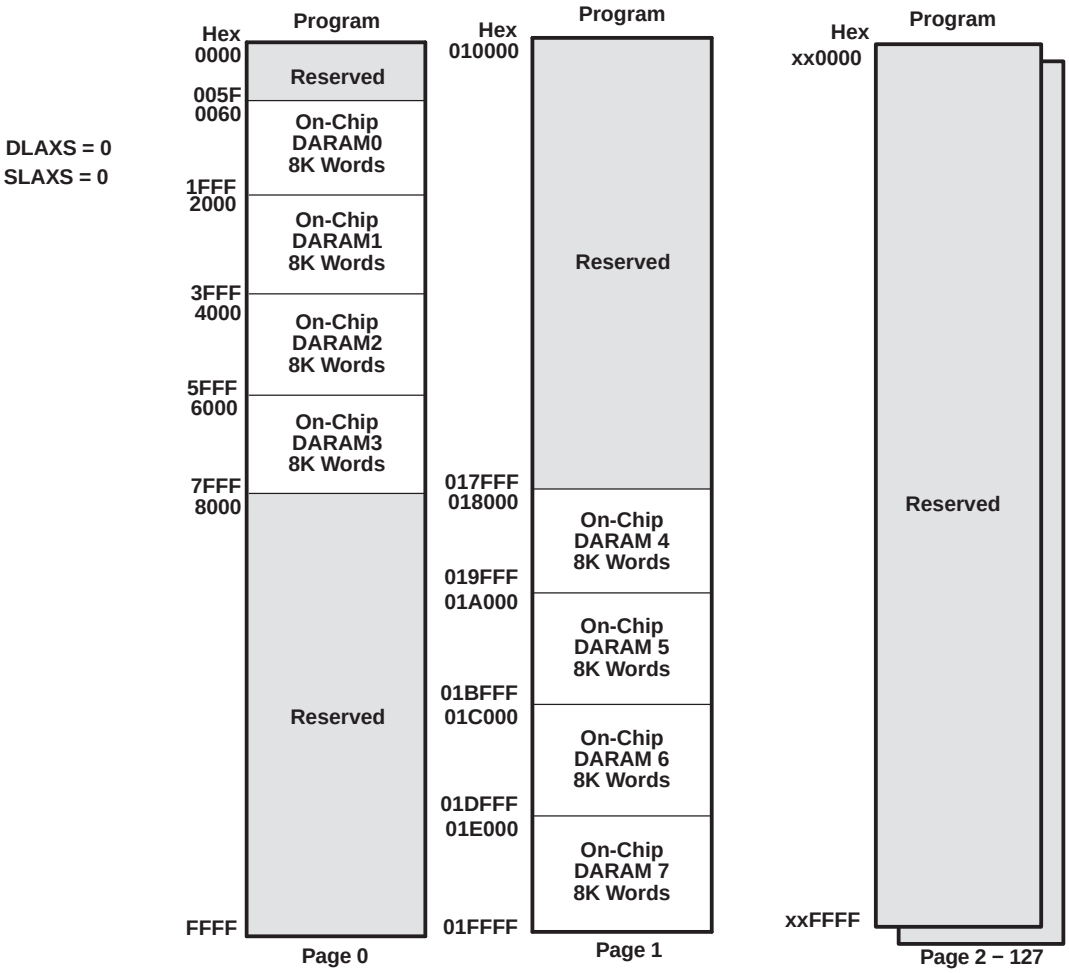

Figure 3-20. On-Chip DMA Memory Map for Program Space (DLAXS = 0 and SLAXS = 0)

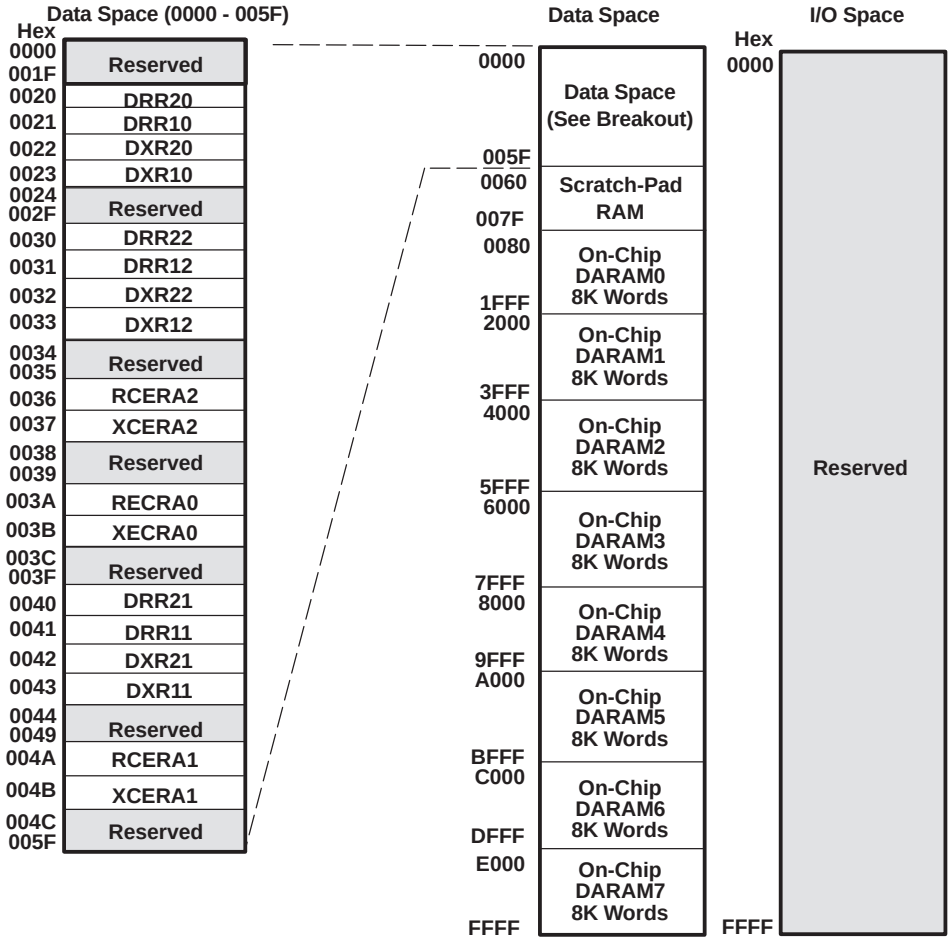

Figure 3-21. On-Chip DMA Memory Map for Data and IO Space (DLAXS = 0 and SLAXS = 0)

3.8.5 DMA Priority Level

Each DMA channel can be independently assigned high- or low-priority relative to each other. Multiple DMA channels that are assigned to the same priority level are handled in a round-robin manner.

3.8.6 DMA Source/Destination Address Modification

The DMA provides flexible address-indexing modes for easy implementation of data management schemes such as autobuffering and circular buffers. Source and destination addresses can be indexed separately and can be post-incremented, post-decremented, or post-incremented with a specified index offset.

3.8.7 DMA in Autoinitialization Mode

The DMA can automatically reinitialize itself after completion of a block transfer. Some of the DMA registers can be preloaded for the next block transfer through the DMA reload registers (DMGSA, DMGDA, DMGCR, and DMGFR). Autoinitialization allows:

- Continuous operation: Normally, the CPU would have to reinitialize the DMA immediately after the completion of the current block transfers, but with the reload registers, it can reinitialize these values for the next block transfer any time after the current block transfer begins.
- Repetitive operation: The CPU does not preload the reload register with new values for each block transfer but only loads them on the first block transfer.

The 5410A DMA has been enhanced to expand the DMA reload register sets. Each DMA channel now has its own DMA reload register set. For example, the DMA reload register set for channel 0 has DMGSA0, DMGDA0, DMGCR0, and DMGFR0 while DMA channel 1 has DMGSA1, DMGDA1, DMGCR1, and DMGFR1, etc.

To utilize the additional DMA reload registers, the AUTOIX bit is added to the DMPREC register as shown in Figure 3-22.

15	14	13	8
FREE	AUTOIX	DPRC[5:0]	

7	6	5	0
INTOSEL		DE[5:0]	

LEGEND: R = Read, W = Write, n = value at reset

Figure 3-22. DMPREC Register

Table 3-13. DMA Reload Register Selection

AUTOIX	DMA RELOAD REGISTER USAGE IN AUTO INIT MODE
0 (default)	All DMA channels use DMGSA0, DMGDA0, DMGCR0 and DMGFR0
1	Each DMA channel uses its own set of reload registers

3.8.8 DMA Transfer Counting

The DMA channel element count register (DMCTRx) and the frame count register (DMFRCx) contain bit fields that represent the number of frames and the number of elements per frame to be transferred.

- Frame count. This 8-bit value defines the total number of frames in the block transfer. The maximum number of frames per block transfer is 128 (FRAME COUNT= 0FFh). The counter is decremented upon the last read transfer in a frame transfer. Once the last frame is transferred, the selected 8-bit counter is reloaded with the DMA global frame reload register (DMGFR) if the AUTOINIT bit is set to 1. A frame count of 0 (default value) means the block transfer contains a single frame.
- Element count. This 16-bit value defines the number of elements per frame. This counter is decremented after the read transfer of each element. The maximum number of elements per frame is 65536(DMCTRn = 0FFFFh). In autoinitialization mode, once the last frame is transferred, the counter is reloaded with the DMA global count reload register (DMGCR).

3.8.9 DMA Transfer in Doubleword Mode

Doubleword mode allows the DMA to transfer 32-bit words in any index mode. In doubleword mode, two consecutive 16-bit transfers are initiated and the source and destination addresses are automatically updated following each transfer. In this mode, each 32-bit word is considered to be one element.

3.8.10 DMA Channel Index Registers

The particular DMA channel index register is selected by way of the SIND and DIND fields in the DMA transfer mode control register (DMMCRn). Unlike basic address adjustment, in conjunction with the frame index DMFRI0 and DMFRI1, the DMA allows different adjustment amounts depending on whether or not the element transfer is the last in the current frame. The normal adjustment value (element index) is contained in the element index registers DMIDX0 and DMIDX1. The adjustment value (frame index) for the end of the frame, is determined by the selected DMA frame index register, either DMFRI0 or DMFRI1.

The element index and the frame index affect address adjustment as follows:

- Element index: For all except the last transfer in the frame, the element index determines the amount to be added to the DMA channel for the source/destination address register (DMSRCx/DMDSTx) as selected by the SIND/DIND bits.
- Frame index: If the transfer is the last in a frame, frame index is used for address adjustment as selected by the SIND/DIND bits. This occurs in both single-frame and multiframe transfers.

3.8.11 DMA Interrupts

The ability of the DMA to interrupt the CPU based on the status of the data transfer is configurable and is determined by the IMOD and DINM bits in the DMA transfer mode control register (DMMCRn). The available modes are shown in Table 3-14.

Table 3-14. DMA Interrupts

MODE	DINM	IMOD	INTERRUPT
ABU (non-decrement)	1	0	At full buffer only
ABU (non-decrement)	1	1	At half buffer and full buffer
Multiframe	1	0	At block transfer complete (DMCTRn = DMSEFCn[7:0] = 0)
Multiframe	1	1	At end of frame and end of block (DMCTRn = 0)
Either	0	X	No interrupt generated
Either	0	X	No interrupt generated

3.8.12 DMA Controller Synchronization Events

The transfers associated with each DMA channel can be synchronized to one of several events. The DSYN bit field of the DMSEFCn register selects the synchronization event for a channel. The list of possible events and the DSYN values are shown in Table 3-15.

Table 3-15. DMA Synchronization Events

DSYN VALUE	DMA SYNCHRONIZATION EVENT
0000b	No synchronization used
0001b	McBSP0 receive event
0010b	McBSP0 transmit event
0011b	McBSP2 receive event
0100b	McBSP2 transmit event
0101b	McBSP1 receive event
0110b	McBSP1 transmit event
0111b	McBSP0 receive event - ABIS mode
1000b	McBSP0 transmit event - ABIS mode
1001b	McBSP2 receive event - ABIS mode
1010b	McBSP2 transmit event - ABIS mode
1011b	McBSP1 receive event - ABIS mode
1100b	McBSP1 transmit event - ABIS mode
1101b	Timer interrupt event
1110b	External interrupt 3
1111b	Reserved

The DMA controller can generate a CPU interrupt for each of the six channels. However, due to a limit on the number of internal CPU interrupt inputs, channels 0, 1, 2, and 3 are multiplexed with other interrupt sources. DMA channels 0, 1, 2, and 3 share an interrupt line with the receive and transmit portions of the McBSP. When the 5410A is reset, the interrupts from these three DMA channels are deselected. The INTOSEL bit field in the DMPREC register can be used to select these interrupts, as shown in Table 3-16.

Table 3-16. DMA Channel Interrupt Selection

INTOSEL Value	IMR/IFR[6]	IMR/IFR[7]	IMR/IFR[10]	IMR/IFR[11]
00b (reset	BRINT2	BXINT2	BRINT1	BXINT1
01b	BRINT2	BXINT2	DMAC2	DMAC3
10b	DMAC0	DMAC1	DMAC2	DMAC3
11b	Reserved			

3.9 General-Purpose I/O Pins

In addition to the standard $\overline{\text{BIO}}$ and XF pins, the 5410A has pins that can be configured for general-purpose I/O. These pins are:

- 18 McBSP pins — BCLKX0/1/2, BCLKR0/1/2, BDR0/1/2, BFSX0/1/2, BFSR0/1/2, BDX0/1/2
- 8 HPI data pins — HD0-HD7

The general-purpose I/O function of these pins is only available when the primary pin function is not required.

3.9.1 McBSP Pins as General-Purpose I/O

When the receive or transmit portion of a McBSP is in reset, its pins can be configured as general-purpose inputs or outputs. For more details on this feature, see Section 3.4.

3.9.2 HPI Data Pins as General-Purpose I/O

The 8-bit bidirectional data bus of the HPI can be used as general-purpose input/output (GPIO) pins when the HPI is disabled (HPIENA = 0) or when the HPI is used in HPI16 mode (HPI16 = 1). Two memory-mapped registers are used to control the GPIO function of the HPI data pins—the general-purpose I/O control register (GPIOCR) and the general-purpose I/O status register (GPIOSR). The GPIOCR is shown in Figure 3-23.

Figure 3-25. Device ID Register (CSIDR) [MMR Address 003Eh]

3.11 Memory-Mapped Registers

The 5410A has 27 memory-mapped CPU registers, which are mapped in data memory space address 0h to 1Fh. Each 5410A device also has a set of memory-mapped registers associated with peripherals. Table 3-17 gives a list of CPU memory-mapped registers (MMRs) available on 5410A. Table 3-18 shows additional peripheral MMRs associated with the 5410A.

Table 3-17. CPU Memory-Mapped Registers

NAME	ADDRESS		DESCRIPTION
	DEC	HEX	
IMR	0	0	Interrupt mask register
IFR	1	1	Interrupt flag register
—	2-5	2-5	Reserved for testing
ST0	6	6	Status register 0

(1) See Table 3-19 for a detailed description of the McBSP control registers and their subaddresses.
(2) See Table 3-20 for a detailed description of the DMA subbank addressed registers.

3.12 McBSP Control Registers and Subaddresses

The control registers for the multichannel buffered serial port (McBSP) are accessed using the subbank addressing scheme. This allows a set or subbank of registers to be accessed through a single memory location. The McBSP subbank address register (SPSA) is used as a pointer to select a particular register within the subbank. The McBSP data register (SPSDx) is used to access (read or write) the selected register. Table 3-19 shows the McBSP control registers and their corresponding subaddresses.

Table 3-19. McBSP Control Registers and Subaddresses

3.13 DMA Subbank Addressed Registers

The direct memory access (DMA) controller has several control registers associated with it. The main control register (DMPREC) is a standard memory-mapped register. However, the other registers are accessed using the subbank addressing scheme. This allows a set or subbank of registers to be accessed through a single memory location. The DMA subbank address (DMSA) register is used as a pointer to select a particular register within the subbank, while the DMA subbank data (DMSD) register or the DMA subbank data register with autoincrement (DMSDI) is used to access (read or write) the selected register.

When the DMSDI register is used to access the subbank, the subbank address is automatically postincremented so that a subsequent access affects the next register within the subbank. This autoincrement feature is intended for efficient, successive accesses to several control registers. If the autoincrement feature is not required, the DMSDN register should be used to access the subbank. Table 3-20 shows the DMA controller subbank addressed registers and their corresponding subaddresses.

Table 3-20. DMA Subbank Addressed Registers

NAME	ADDRESS	SUB-ADDRESS	DESCRIPTION
DMSRC0	56h/57h	00h	DMA channel 0 source address register

4 Support

4.1 Documentation Support

Extensive documentation supports all TMS320™ DSP family of devices from product announcement through applications development. The following types of documentation are available to support the design and use of the C5000™ platform of DSPs:

SPRU307: TMS320C54x DSP Family Functional Overview

Provides a functional overview of the devices included in the TMS320C54x™ DSP generation of digital signal processors. Included are descriptions of the CPU architecture, bus structure, memory structure, on-chip peripherals, and instruction set.

SPRA164: Calculation of TMS320LC54x Power Dissipation

Describes the power-saving features of the TMS320LC54x and presents techniques for analyzing systems and device conditions to determine operating current levels and power dissipaton. From this information, informed decisions can be made regarding power supply requirements and thermal management considerations.

The five-volume *TMS320C54x DSP Reference Set* consists of:

SPRU131: TMS320C54x DSP Reference Set, Volume 1: CPU

Describes the TMS320C54x 16-bit fixed-point general-purpose digital signal processors. Covered are its architecture, internal register structure, data and program addressing, and the instruction pipeline. Also includes development support information, parts lists, and design considerations for using the XDS510 emulator.

SPRU172: TMS320C54x DSP Reference Set, Volume 2: Mnemonic Instruction Set

Describes the TMS320C54x digital signal processor mnemonic instructions individually. Also includes a summary of instruction set classes and cycles.

SPRU179: TMS320C54x DSP Reference Set, Volume 3: Algebraic Instruction Set

Describes the TMS320C54x digital signal processor algebraic instructions individually. Also includes a summary of instruction set classes and cycles.

SPRU173: TMS320C54x DSP Reference Set, Volume 4: Applications Guide

Describes software and hardware applications for the TMS320C54x digital signal processor. Also includes development support information, parts lists, and design considerations for using the XDS510 emulator.

SPRU302: TMS320C54x DSP Reference Set, Volume 5: Enhanced Peripherals

Describes the enhanced peripherals available on the TMS320C54x digital signal processors. Includes the multichannel buffered serial ports (McBSPs), direct memory access (DMA) controller, interprocessor communications, and the HPI-8 and HPI-16 host port interfaces.

The reference set describes in detail the TMS320C54x™ DSP products currently available and the hardware and software applications, including algorithms, for fixed-point TMS320™ DSP family of devices.

A series of DSP textbooks is published by Prentice-Hall and John Wiley & Sons to support digital signal processing research and education. The TMS320 DSP newsletter, *Details on Signal Processing*, is published quarterly and distributed to update TMS320 DSP customers on product information.

Information regarding TI DSP porducts is also available on the web at *www.ti.com*.

4.2 Device and Development-Support Tool Nomenclature

To designate the stages in the product development cycle, TI assigns prefixes to the part numbers of all TMS320 DSP devices and support tools. Each TMS320 DSP commercial family member has one of three prefixes: TMX, TMP, or TMS (e.g., TMS320C6412GDK600). Texas Instruments recommends two of three possible prefix designators for its support tools: TMDX and TMDS. These prefixes represent evolutionary stages of product development from engineering prototypes (TMX/TMDX) through fully qualified production devices/tools (TMS/TMDS).

Device development evolutionary flow:

TMX Experimental device that is not necessarily representative of the final device's electrical specifications

TMP Final silicon die that conforms to the device's electrical specifications but has not completed quality and reliability verification

TMS Fully qualified production device

Support tool development evolutionary flow:

TMDX Development-support product that has not yet completed Texas Instruments internal qualification testing.

TMDS Fully qualified development-support product

TMX and TMP devices and TMDX development-support tools are shipped with appropriate disclaimers describing their limitations and intended uses.

"Developmental product is intended for internal evaluation purposes."

TMS devices and TMDS development-support tools have been characterized fully, and the quality and reliability of the device have been demonstrated fully. TI's standard warranty applies.

Predictions show that prototype devices (TMX or TMP) have a greater failure rate than the standard production devices. Texas Instruments recommends that these devices not be used in any production system because their expected end-use failure rate still is undefined. Only qualified production devices are to be used.

5 Electrical Specifications

This section provides the absolute maximum ratings and the recommended operating conditions for the TMS320VC5410A DSP.

5.1 Absolute Maximum Ratings

The list of absolute maximum ratings are specified over operating case temperature. Stresses beyond those listed under "absolute maximum ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under Section 5.2 is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability. All voltage values are with respect to DV_{SS}. Figure 5-1 provides the test load circuit values for a 3.3-V device.

DV_{DD}	Supply voltage I/O range	– 0.3 V to 4.0 V
CV_{DD}	Supply voltage core range	– 0.3 V to 2.0 V
V_I	Input voltage range	– 0.3 V to 4.5 V
V_O	Output voltage range	– 0.3 V to 4.5 V
T_C	Operating case temperature range	– 40°C to 100°C
T_{stg}	Storage temperature range	– 55°C to 150°C

5.2 Recommended Operating Conditions

			MIN	NOM	MAX	UNIT
DV_{DD}	Device supply voltage, I/O		2.7	3.3	3.6	V
CV_{DD}	Device supply voltage, core (VC5410A–160)		1.55	1.6	1.65	V
CV_{DD}	Device supply voltage, core (VC5410A–120)		1.42	1.5	1.65	V
DV_{SS}, CV_{SS}	Supply voltage, GND			0		V
V_{IH}	High-level input voltage, I/O	$\overline{RS}$, $\overline{INTn}$, $\overline{NMI}$, X2/CLKIN, CLKMDn, BCLKRn, BCLKXn, $\overline{HCS}$, $\overline{HDS1}$, $\overline{HDS2}$, $\overline{HAS}$, $\overline{TRST}$, TCK, $\overline{BIO}$, Dn, An, HDn(DV_{DD} = 2.7 V to 3.6 V)	2.4		DV_{DD} + 0.3	V
		All other inputs	2		DV_{DD} + 0.3	
V_{IL}	Low-level input voltage		– 0.3		0.8	V
I_{OH}	High-level output current(1)(2)				– 8	mA
I_{OL}	Low-level output current(1)(2)				8	mA
T_C	Operating case temperature		– 40		100	°C

(1) These output current limits are used for the test conditions on V_{OL} and V_{OH}, except where noted otherwise.
(2) The maximum output currents are DC values only. Transient currents may exceed these values.

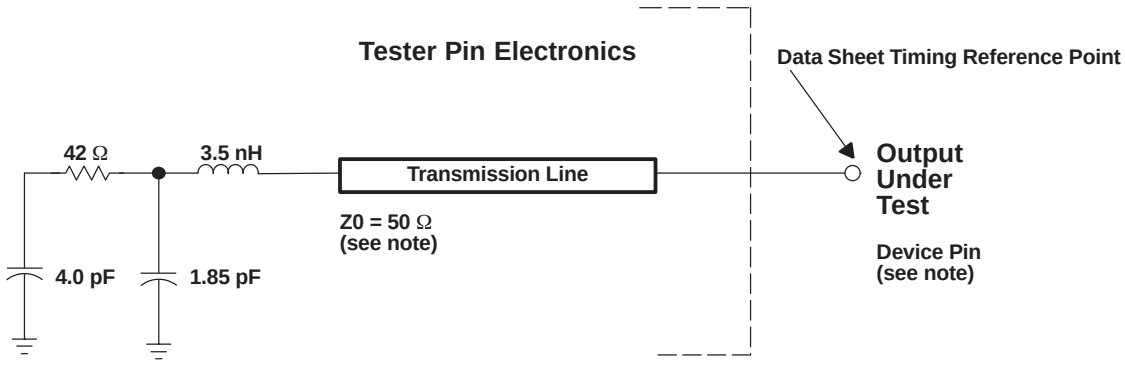
5.3 Electrical Characteristics Over Recommended Operating Case Temperature Range (Unless Otherwise Noted)

PARAMETER			TEST CONDITIONS	MIN	TYP(1)	MAX	UNIT
V_{OH}	High-level output voltage(2)		(DV_{DD} = 2.7 V to 3.0 V), I_{OH} = –2 mA	2.2			V
			(DV_{DD} = 3.0 V to 3.6 V), I_{OH} = MAX	2.4			
V_{OL}	Low-level output voltage(2)		I_{OL} = MAX			0.4	V
I_{IZ}	Input current in high impedance	A[16:0]	DV_{DD} = MAX, V_O = DV_{SS} to DV_{DD}	– 275		275	µA
I_I	Input current (V_I = DV_{SS} to DV_{DD})	X2/CLKIN		– 40		40	µA
		$\overline{TRST}$, HPI16	With internal pulldown	– 10		800	µA
		HPIENA	With internal pulldown, $\overline{RS}$ = 0	– 10		400	
		TMS, TCK, TDI, HPI(3)	With internal pullups	– 400		10	
		D[15:0], HD[7:0]	Bus holders enabled, DV_{DD} = MAX(4)	– 275		275	
		All other input-only pins		– 5		5	
I_{DDC}	Supply current, core CPU		CV_{DD} = 1.6 V, f_x = 160 MHz,(5) T_C = 25°C		60(6)		mA
I_{DDP}	Supply current, pins		DV_{DD} = 3.0 V, f_x = 160 MHz,(5) T_C = 25°C		40(7)		mA
I_{DD}	Supply current, standby	IDLE2	PLL × 1 mode, 20 MHz input		2		mA
		IDLE3, divide-by-two mode, CLKIN stopped	T_C = 25°C		1(8)		mA
			T_C = 100°C		30		
C_i	Input capacitance				5		pF
C_o	Output capacitance				5		pF

(1) All values are typical unless otherwise specified.
(2) All input and output voltage levels except $\overline{RS}$, $\overline{INT0}$–$\overline{INT3}$, $\overline{NMI}$, X2/CLKIN, CLKMD1–CLKMD3, BCLKR0 – BCLKR2, BCLKX0 – BCLKX2, $\overline{HCS}$, $\overline{HAS}$, $\overline{HDS1}$, $\overline{HDS2}$, $\overline{BIO}$, TCK, $\overline{TRST}$, D0 – D15, HD0 – HD7, A0 – A16 are LVTTL-compatible.
(3) HPI input signals except for HPIENA and HPI16, when HPIENA = 0.
(4) $V_{IL(MIN)} \le V_I \le V_{IL(MAX)}$ or $V_{IH(MIN)} \le V_I \le V_{IH(MAX)}$
(5) Clock mode: PLL × 1 with external source
(6) This value was obtained with 50% usage of MAC and 50% usage of NOP instructions. Actual operating current varies with program being executed.
(7) This value was obtained with single-cycle external writes, CLKOFF = 0 and load = 15 pF. For more details on how this calculation is performed, refer to the *Calculation of TMS320LC54x Power Dissipation* application report (literature number SPRA164).
(8) Material with high I_{DD} has been observed with a typical I_{DD} value of 5 to 10 mA during high temperature testing.

5.4 Test Load Circuit

This test load circuit is used to measure all switching characteristics provided in this data manual.



NOTE: The data sheet provides timing at the device pin. For output timing analysis, the tester pin electronics and its transmission line effects must taken into account. A transmission line with a delay of 2 ns or longer can be used to produce the desired transmission line effect. The transmission line is intended as a load only. It is not necessary to add or subtract the transmission line delay (2 ns or longer) from the data sheet timings.

Input requirements in this data sheet are tested with an input slew rate of < 4 Volts per nanosecond (4 V/ns) at the device pin.

Figure 5-1. Tester Pin Electronics

5.5 Timing Parameter Symbology

Timing parameter symbols used in the timing requirements and switching characteristics tables are created in accordance with JEDEC Standard 100. To shorten the symbols, some of the pin names and other related terminology have been abbreviated as follows:

Lowercase subscripts and their meanings:

a	access time
c	cycle time (period)
d	delay time
dis	disable time
en	enable time
f	fall time
h	hold time
r	rise time
su	setup time
t	transition time
v	valid time
w	pulse duration (width)
X	Unknown, changing, or don't care level

Letters and symbols and their meanings:

H	High
L	Low
V	Valid
Z	High impedance

5.6 Internal Oscillator With External Crystal

The internal oscillator is enabled by selecting the appropriate clock mode at reset (this is device-dependent; see Section 3.6) and connecting a crystal or ceramic resonator across X1 and X2/CLKIN. The CPU clock frequency is one-half, one-fourth, or a multiple of the oscillator frequency. The multiply ratio is determined by the bit settings in the CLKMD register.

The crystal should be in fundamental-mode operation, and parallel resonant, with an effective series resistance of 30Ω maximum and power dissipation of 1 mW. The connection of the required circuit, consisting of the crystal and two load capacitors, is shown in Figure 5-2. The load capacitors, C_1 and C_2, should be chosen such that the equation below is satisfied. C_L (recommended value of 10 pF)in the equation is the load specified for the crystal.

$$C_L = \frac{C_1 C_2}{(C_1 + C_2)}$$

Table 5-1. Input Clock Frequency Characteristics

		MIN	MAX	UNIT
f_x	Input clock frequency	10 (1)	20 (2)	MHz

(1) This device utilizes a fully static design and therefore can operate with $t_{c(CI)}$ approaching ∞. The device is characterized at frequencies approaching 0 Hz
(2) It is recommended that the PLL multiply by N clocking option be used for maximum frequency operation.

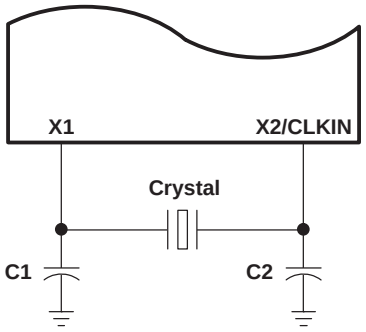


Figure 5-2. Internal Divide-By-Two Clock Option With External Crystal

5.7 Clock Options

The frequency of the reference clock provided at the CLKIN pin can be divided by a factor of two or four or multiplied by one of several values to generate the internal machine cycle.

5.7.1 Divide-By-Two and Divide-By-Four Clock Options

The frequency of the reference clock provided at the X2/CLKIN pin can be divided by a factor of two or four to generate the internal machine cycle. The selection of the clock mode is described in Section 3.6.

When an external clock source is used, the frequency injected must conform to specifications listed in Table 5-3.

An external frequency source can be used by applying an input clock to X2/CLKIN with X1 left unconnected.

Table 5-2 shows the configuration options for the CLKMD pins that generate the external divide-by-2 or divide-by-4 clock option.

Table 5-2. Clock Mode Pin Settings for the Divide-By-2 and By Divide-By-4 Clock Options

CLKMD1	CLKMD2	CLKMD3	Clock Mode
0	0	0	1/2, PLL disabled
1	0	1	1/4, PLL disabled
1	1	1	1/2, PLL disabled

Table 5-3 and Table 5-4 assume testing over recommended operating conditions and H = $0.5t_{c(CO)}$ (see Figure 5-3).

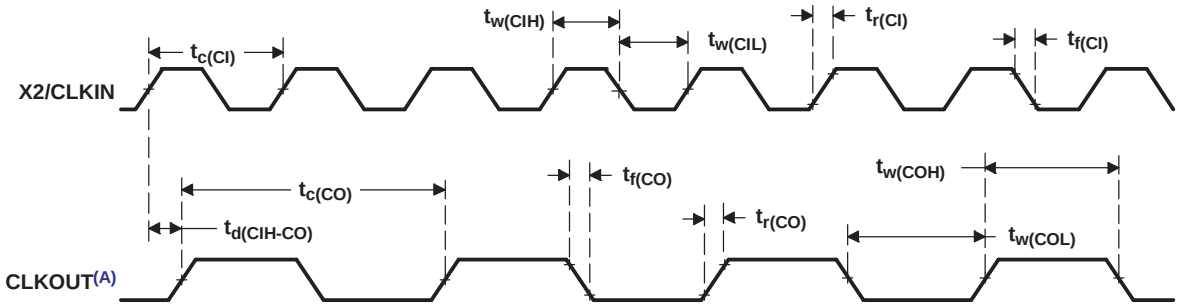
Table 5-3. Divide-By-2 and Divide-By-4 Clock Options Timing Requirements

		5410A-120 5410A-160		UNIT
		MIN	MAX	
$t_{c(CI)}$	Cycle time, X2/CLKIN	20		ns
$t_{f(CI)}$	Fall time, X2/CLKIN		4	ns
$t_{r(CI)}$	Rise time, X2/CLKIN		4	ns
$t_{w(CIL)}$	Pulse duration, X2/CLKIN low	4		ns
$t_{w(CIH)}$	Pulse duration, X2/CLKIN high	4		ns

Table 5-4. Divide-By-2 and Divide-By-4 Clock Options Switching Characteristics

Parameter		5410A-120			5410A-160			UNIT
		MIN	TYP	MAX	MIN	TYP	MAX	
$t_{c(CO)}$	Cycle time, CLKOUT	8.33(1)		(2)	6.25(1)		(2)	ns
$t_{d(CIH-CO)}$	Delay time, X2/CLKIN high to CLKOUT high/low	4	7	11	4	7	11	ns
$t_{f(CO)}$	Fall time, CLKOUT		1			1		ns
$t_{r(CO)}$	Rise time, CLKOUT		1			1		ns
$t_{w(COL)}$	Pulse duration, CLKOUT low	H –3	H	H + 3	H –3	H	H + 3	ns
$t_{w(COH)}$	Pulse duration, CLKOUT high	H – 3	H	H + 3	H – 3	H	H + 3	ns

(1) It is recommended that the PLL clocking option be used for maximum frequency operation.
(2) This device utilizes a fully static design and therefore can operate with $t_{c(CI)}$ approaching ∞. The device is characterized at frequencies approaching 0 Hz.



A. The CLKOUT timing in this diagram assumes the CLKOUT divide factor (DIVFCT field in the BSCR) is configured as 00 (CLKOUT not divided). DIVFCT is configured as CLKOUT divided-by-4 mode following reset.

Figure 5-3. External Divide-By-Two Clock Timing

5.7.2 Multiply-By-N Clock Option (PLL Enabled)

The frequency of the reference clock provided at the X2/CLKIN pin can be multiplied by a factor of N to generate the internal machine cycle. The selection of the clock mode and the value of N is described in Section 3.6. Following reset, the software PLL can be programmed for the desired multiplication factor. Refer to the *TMS320C54x DSP Reference Set*, *Volume 1: CPU and Peripherals* (literature number SPRU131) for detailed information on programming the PLL.

When an external clock source is used, the external frequency injected must conform to specifications listed in Table 5-5.

Table 5-5 and Table 5-6 assume testing over recommended operating conditions and H = $0.5t_{c(CO)}$ (see Figure 5-4).

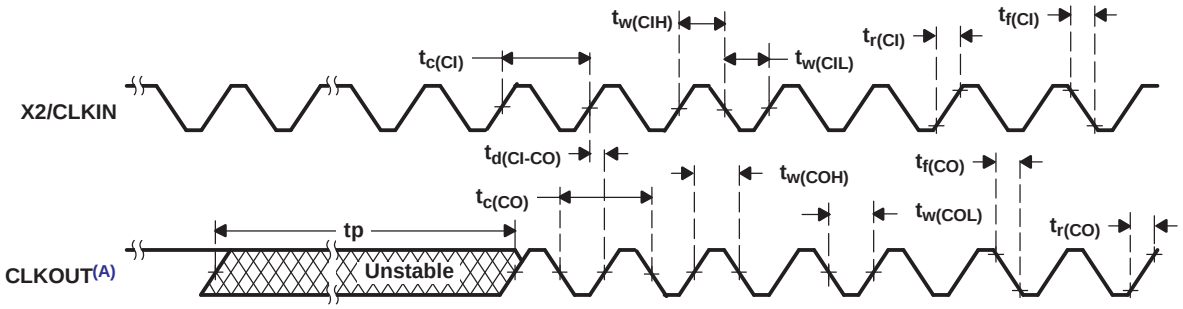
Table 5-5. Multiply-By-N Clock Option Timing Requirements

			5410A-120 5410A-160		UNIT
			MIN	MAX	
$t_{c(CI)}$	Cycle time, X2/CLKIN	Integer PLL multiplier N (N = 1–15)(1)	20	200	ns
		PLL multiplier N = x.5(1)	20	100	
		PLL multiplier N = x.25, x.75(1)	20	50	
$t_{f(CI)}$	Fall time, X2/CLKIN			4	ns
$t_{r(CI)}$	Rise time, X2/CLKIN			4	ns
$t_{w(CIL)}$	Pulse duration, X2/CLKIN low		4		ns
$t_{w(CIH)}$	Pulse duration, X2/CLKIN high		4		ns

(1) N is the multiplication factor.

Table 5-6. Multiply-By-N Clock Option Switching Characteristics

PARAMETER		5410A-120			5410A-160			UNIT
		MIN	TYP	MAX	MIN	TYP	MAX	
$t_{c(CO)}$	Cycle time, CLKOUT	8.33			6.25			ns
$t_{d(CI-CO)}$	Delay time, X2/CLKIN high/low to CLKOUT high/low	4	7	11	4	7	11	ns
$t_{f(CO)}$	Fall time, CLKOUT		2			2		ns
$t_{r(CO)}$	Rise time, CLKOUT		2			2		ns
$t_{w(COL)}$	Pulse duration, CLKOUT low		H			H		ns
$t_{w(COH)}$	Pulse duration, CLKOUT high		H			H		ns
t_p	Transitory phase, PLL lock-up time			30			30	ms



A. The CLKOUT timing in this diagram assumes the CLKOUT divide factor (DIVFCT field in the BSCR) is configured as 00 (CLKOUT not divided). DIVFCT is configured as CLKOUT divided-by-4 mode following reset.

Figure 5-4. Multiply-By-One Clock Timing

5.8 Memory and Parallel I/O Interface Timing

Address delay times are longer for cycles immediatly following a HOLD operation. All timings related to the address bus have been seperated in to two cases; one showing normal operation and the other showing the delays related to the HOLD operation.

5.8.1 Memory Read

External memory reads can be performed in consecutive or nonconsecutive mode under control of the $\overline{\text{CONSEC}}$ bit in the BSCR. Table 5-7 and Table 5-8 assume testing over recommended operating conditions with $\overline{\text{MSTRB}}$ = 0 and H = 0.5$t_{c(CO)}$ (see Figure 5-5 and Figure 5-6).

Table 5-7. Memory Read Timing Requirements

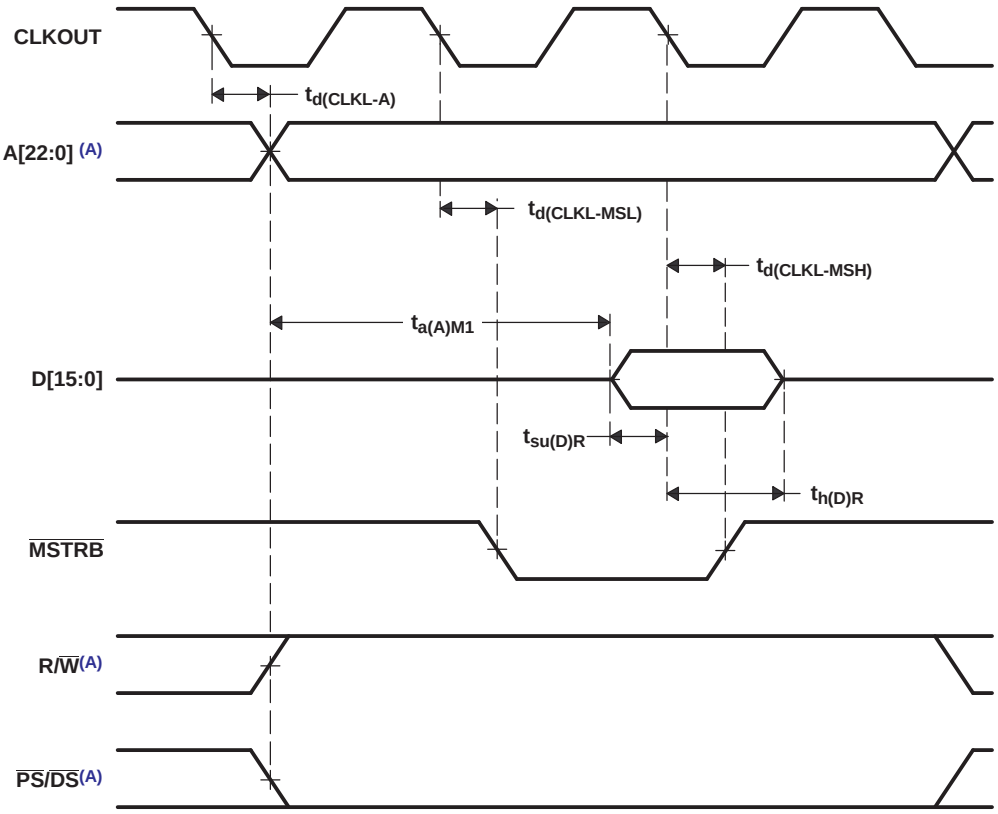
			5410A-120 5410A-160		UNIT
			MIN	MAX	
$t_{a(A)M1}$	Access time, read data access from address valid, first read access(1)	For accesses not immediately following a HOLD operation		4H–9	ns
		For a read accesses immediately following a HOLD operation		4H–11	ns
$t_{a(A)M2}$	Access time, read data access from address valid, consecutive read accesses(1)			2H–9	ns
$t_{su(D)R}$	Setup time, read data valid before CLKOUT low		7		ns
$t_{h(D)R}$	Hold time, read data valid after CLKOUT low		0		ns

(1) Address,R/$\overline{\text{W}}$, $\overline{\text{PS}}$, $\overline{\text{DS}}$, and $\overline{\text{IS}}$ timings are all included in timings referenced as address.

Table 5-8. Memory Read Switching Characteristics

PARAMETER			5410A-120 5410A-160		UNIT
			MIN	MAX	
$t_{d(CLKL-A)}$	Delay time, CLKOUT low to address valid(1)	For accesses not immediately following a HOLD operation	– 1	4	ns
		For a read accesses immediately following a HOLD operation	– 1	6	ns
$t_{d(CLKL-MSL)}$	Delay time, CLKOUT low to $\overline{\text{MSTRB}}$ low		– 1	4	ns
$t_{d(CLKL-MSH)}$	Delay time, CLKOUT low to $\overline{\text{MSTRB}}$ high		– 1	4	ns

(1) Address,R/$\overline{\text{W}}$, $\overline{\text{PS}}$, $\overline{\text{DS}}$, and $\overline{\text{IS}}$ timings are all included in timings referenced as address.



A. Address,R/$\overline{W}$, $\overline{PS}$, $\overline{DS}$, and $\overline{IS}$ timings are all included in timings referenced as address.

$t_{w(INTH)S}$	Pulse duration, $\overline{\text{INTn}}$, $\overline{\text{NMI}}$ high (synchronous)	2H+2		ns
$t_{w(INTH)A}$	Pulse duration, $\overline{\text{INTn}}$, $\overline{\text{NMI}}$ high (asynchronous)	4H		ns
$t_{w(INTL)S}$	Pulse duration, $\overline{\text{INTn}}$, $\overline{\text{NMI}}$ low (synchronous)	2H+2		ns
$t_{w(INTL)A}$	Pulse duration, $\overline{\text{INTn}}$, $\overline{\text{NMI}}$ low (asynchronous)	4H		ns
$t_{w(INTL)WKP}$	Pulse duration, $\overline{\text{INTn}}$, $\overline{\text{NMI}}$ low for IDLE2/IDLE3 wakeup	7		ns
$t_{su(RS)}$	Setup time, $\overline{\text{RS}}$ before X2/CLKIN low(4)	3		ns
$t_{su(BIO)}$	Setup time, $\overline{\text{BIO}}$ before CLKOUT low	7		ns
$t_{su(INT)}$	Setup time, $\overline{\text{INTn}}$, $\overline{\text{NMI}}$, $\overline{\text{RS}}$ before CLKOUT low	7		ns
$t_{su(MPMC)}$	Setup time, MP/$\overline{\text{MC}}$ before CLKOUT low	5		ns

(1) The external interrupts ($\overline{\text{INT0}}$–$\overline{\text{INT3}}$, $\overline{\text{NMI}}$) are synchronized to the core CPU by way of a two-flip-flop synchronizer that samples these inputs with consecutive falling edges of CLKOUT. The input to the interrupt pins is required to represent a 1-0-0 sequence at the timing that is corresponding to three CLKOUTs sampling sequence.
(2) If the PLL mode is selected, then at power-on sequence, or at wakeup from IDLE3, $\overline{\text{RS}}$ must be held low for at least 50 µs to ensure synchronization and lock-in of the PLL.
(3) Note that $\overline{\text{RS}}$ may cause a change in clock frequency, therefore changing the value of H.
(4) The diagram assumes clock mode is divide-by-2 and the CLKOUT divide factor is set to no-divide mode (DIVFCT=00 field in the BSCR).

5.15 Host-Port Interface Timing

5.15.1 HPI8 Mode

Table 5-32 and Table 5-33 assume testing over recommended operating conditions and P = 0.5 * processor clock (see Figure 5-28 through Figure 5-31). In the following tables, DS refers to the logical OR of $\overline{HCS}$, $\overline{HDS1}$, and $\overline{HDS2}$. HD refers to any of the HPI data bus pins (HD0, HD1, HD2, etc.). HAD stands for HCNTL0, HCNTL1, and HR/$\overline{W}$.

Table 5-32. HPI8 Mode Timing Requirements

		5410A-120 5410A-160		UNIT
		MIN	MAX

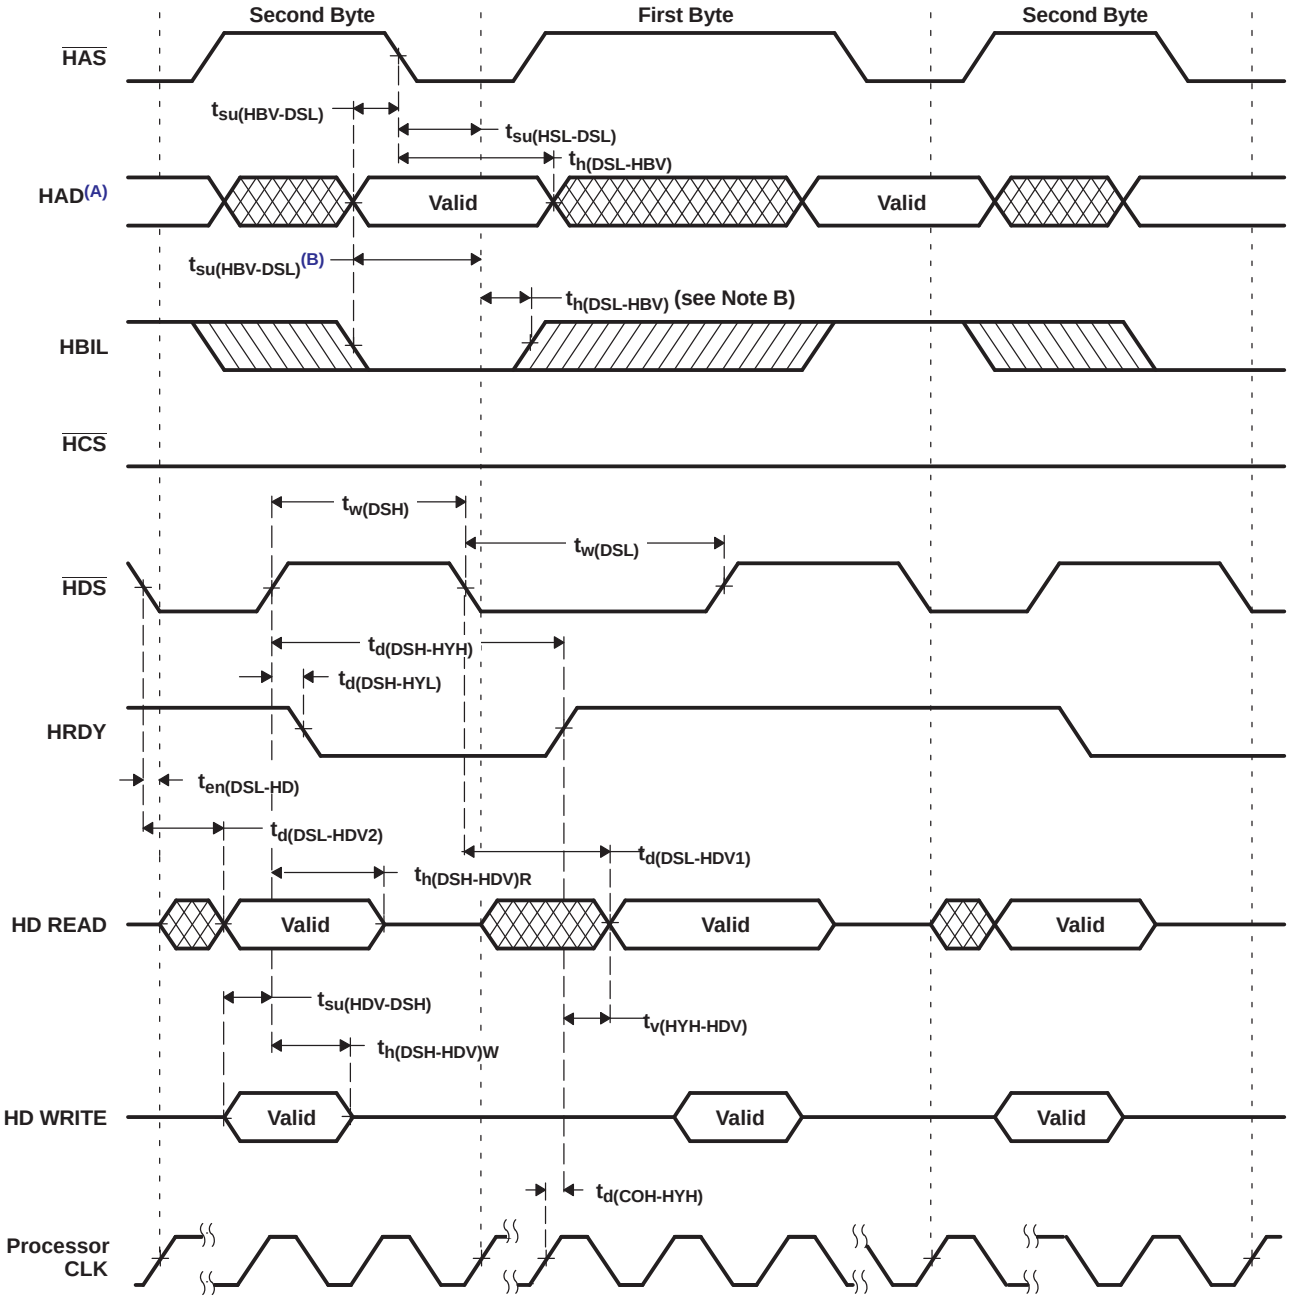
$t_{su(HSL-DSL)}$	Setup time, $\overline{HAS}$ low before DS low	8		ns
$t_{w(DSL)}$	Pulse duration, DS low	13		ns
$t_{w(DSH)}$	Pulse duration, DS high	7		ns
$t_{su(HDV-DSH)}$	Setup time, HD valid before DS high, HPI write	3		ns
$t_{h(DSH-HDV)W}$	Hold time, HD valid after DS high, HPI write	2		ns
$t_{su(GPIO-COH)}$	Setup time, HDx input valid before CLKOUT high, HDx configured as general-purpose input	3		ns
$t_{h(GPIO-COH)}$	Hold time, HDx input valid before CLKOUT high, HDx configured as general-purpose input	0		ns

Table 5-33. HPI8 Mode Switching Characteristics

PARAMETER			5410A-120 5410A-160		UNIT
			MIN	MAX	
$t_{en(DSL-HD)}$	Enable time, HD driven from DS low		0	10	ns
$t_{d(DSL-HDV1)}$	Delay time, DS low to HD valid for first byte of an HPI read	Case 1a: Memory accesses when DMAC is active in 16-bit mode and $t_{w(DSH)} < I8H$ (1)		18P+10–$t_{w(DSH)}$	ns
		Case 1b: Memory accesses when DMAC is active in 32-bit mode and $t_{w(DSH)} \geq I8H$ (1)		36P+10–$t_{w(DSH)}$	
		Case 1c: Memory accesses when DMAC is active in 16-bit mode and $t_{w(DSH)} \geq I8H$ (1)		10	
		Case 1d: Memory accesses when DMAC is active in 32-bit mode and $t_{w(DSH)} \geq I8H$ (1)		10	
		Case 2a: Memory accesses when DMAC is inactive and $t_{w(DSH)} < 10H$ (1)		10P+10–$t_{w(DSH)}$	
		Case 2b: Memory accesses when DMAC is inactive and $t_{w(DSH)} \geq 10H$ (1)		10	
		Case 3: Register accesses		10	
$t_{d(DSL-HDV2)}$	Delay time, DS low to HD valid for second byte of an HPI read			10	ns
$t_{h(DSH-HDV)R}$	Hold time, HD valid after DS high, for a HPI read		0		ns
$t_{v(HYH-HDV)}$	Valid time, HD valid after HRDY high			2	ns
$t_{d(DSH-HYL)}$	Delay time, DS high to HRDY low (2)			8	ns
$t_{d(DSH-HYH)}$	Delay time, DS high to HRDY high (2)	Case 1a: Memory accesses when DMAC is active in 16-bit mode (1)		18P+6	ns
		Case 1b: Memory accesses when DMAC is active in 32-bit mode (1)		36P+6	
		Case 2: Memory accesses when DMAC is inactive (1)		10P+6	
		Case 3: Write accesses to HPIC register (3)		6P+6	
$t_{d(HCS-HRDY)}$	Delay time, $\overline{HCS}$ low/high to HRDY low/high			6	ns
$t_{d(COH-HYH)}$	Delay time, CLKOUT high to HRDY high			9	ns
$t_{d(COH-HTX)}$	Delay time, CLKOUT high to $\overline{HINT}$ change			6	ns
$t_{d(COH-GPIO)}$	Delay time, CLKOUT high to HDx output change. HDx is configured as a general-purpose output			5	ns

(1) DMAC stands for direct memory access controller (DMAC). The HPI8 shares the internal DMA bus with the DMAC, thus HPI8 access times are affected by DMAC activity.
(2) The HRDY output is always high when the $\overline{HCS}$ input is high, regardless of DS timings.
(3) This timing applies when writing a one to the DSPINT bit or $\overline{HINT}$ bit of the HPIC register. All other writes to the HPIC occur asynchronously, and do not cause HRDY to be deasserted.



A. HAD refers to HCNTL0, HCNTL1, and HR/$\overline{W}$.

B. When $\overline{HAS}$ is not used ($\overline{HAS}$ always high)

Figure 5-28. HPI-8 Mode Timing, Using $\overline{HDS}$ to Control Accesses ($\overline{HCS}$ Always Low)

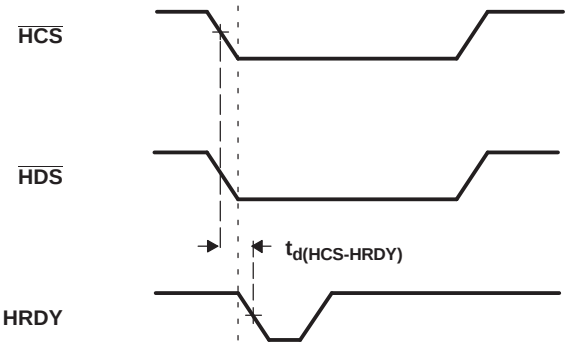


Figure 5-29. HPI-8 Mode Timing, Using HCS to Control Accesses

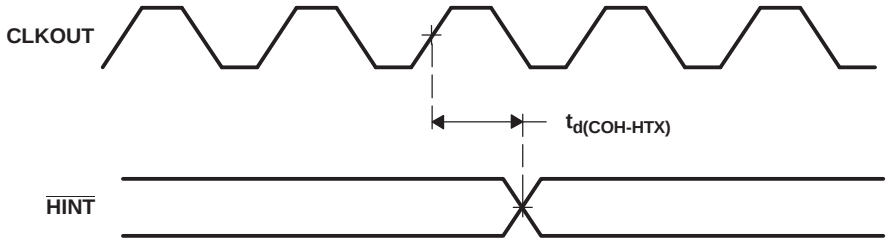

Figure 5-30. HPI-8 Mode, HINT Timing

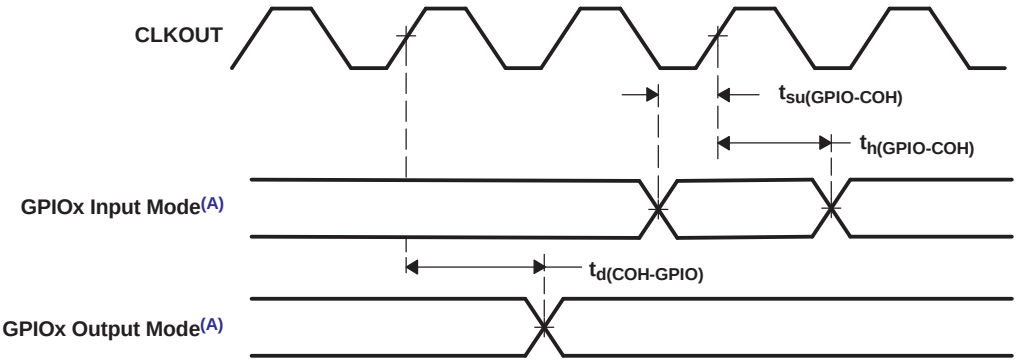

A. GPIOx refers to HD0, HD1, HD2, ...HD7, when the HD bus is configured for general-purpose input/output (I/O).

Figure 5-31. GPIOx Timings

5.15.2 HPI16 Mode

Table 5-34 and Table 5-35 assume testing over recommended operating conditions and P = 0.5 * processor clock (see Figure 5-32 through Figure 5-34). In the following tables, DS refers to the logical OR of $\overline{HCS}$, $\overline{HDS1}$, and $\overline{HDS2}$, and HD refers to any of the HPI data bus pins (HD0, HD1, HD2, etc.). These timings are shown assuming that $\overline{HDS}$ is the signal controlling the transfer. See the *TMS320C54x DSP Reference Set,Volume 5: Enhanced Peripherals* (literature number SPRU302) for addition information.

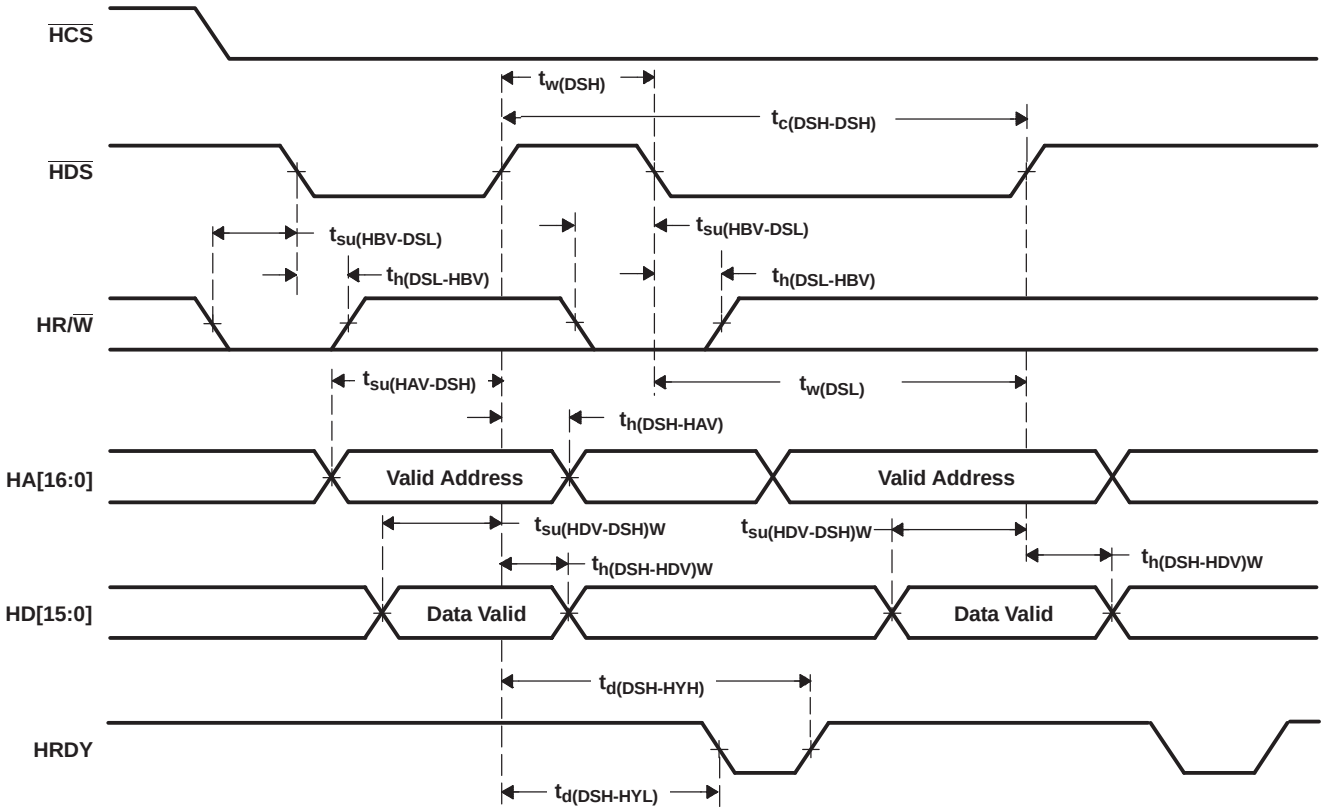

Figure 5-33. HPI-16 Mode, Nonmultiplexed Write Timings

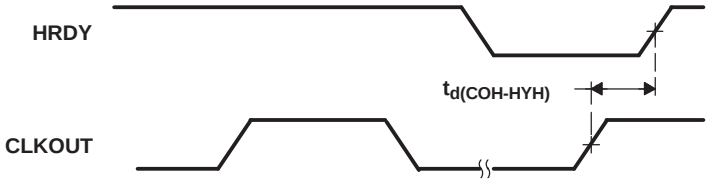

Figure 5-34. HPI-16 Mode, HRDY Relative to CLKOUT

6 Mechanical Data

The following mechanical package diagram(s) reflect the most current released mechanical data available for the designated device(s).

6.1 Package Thermal Resistance Characteristics

Table 6-1 provides the estimated thermal resistance characteristics for the recommended package types used on the device.

Table 6-1. Thermal Resistance Characteristics

PARAMETER	GGU PACKAGE	PGE PACKAGE	UNIT
$R_{\theta JA}$	38	56	°C/W
$R_{\theta JC}$	5	5	°C/W

(1) **Status:** For more details on status, see our product life cycle.

(2) **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

(3) **RoHS values:** Yes, No, RoHS Exempt. See the TI RoHS Statement for additional information and value definition.

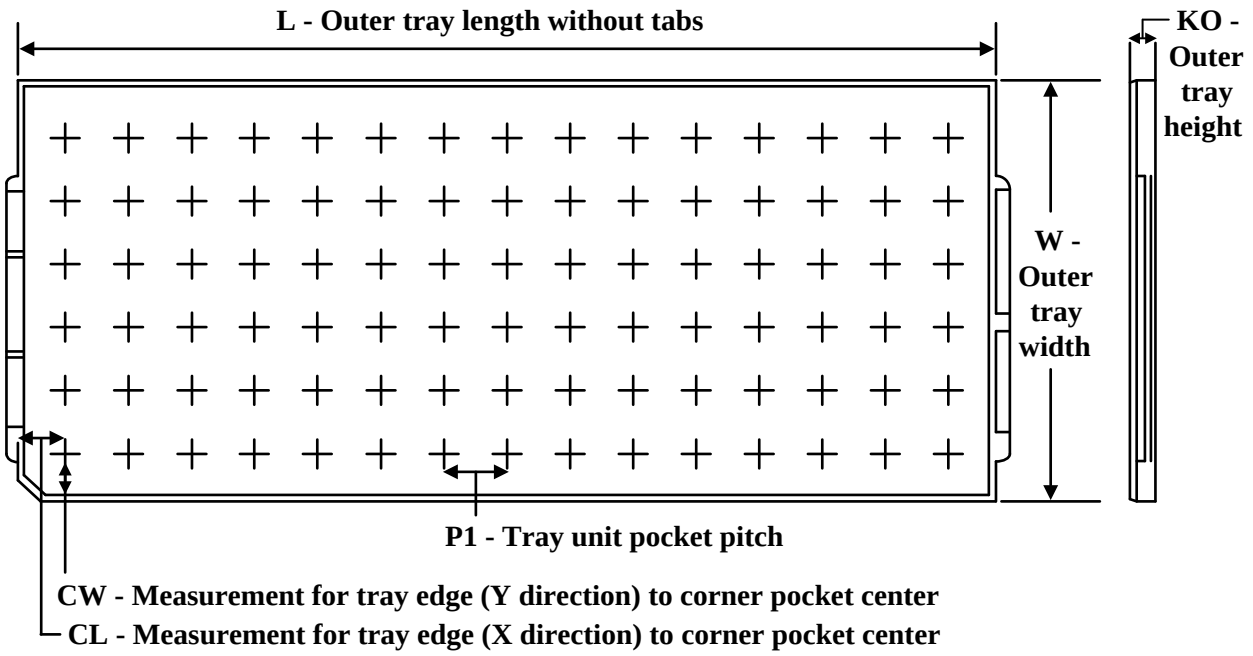
(4) **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

(5) **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

(6) **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.

TRAY



Chamfer on Tray corner indicates Pin 1 orientation of packed units.

*All dimensions are nominal

Device	Package Name	Package Type	Pins	SPQ	Unit array matrix	Max temperature (°C)	L (mm)	W (mm)	K0 (µm)	P1 (mm)	CL (mm)	CW (mm)

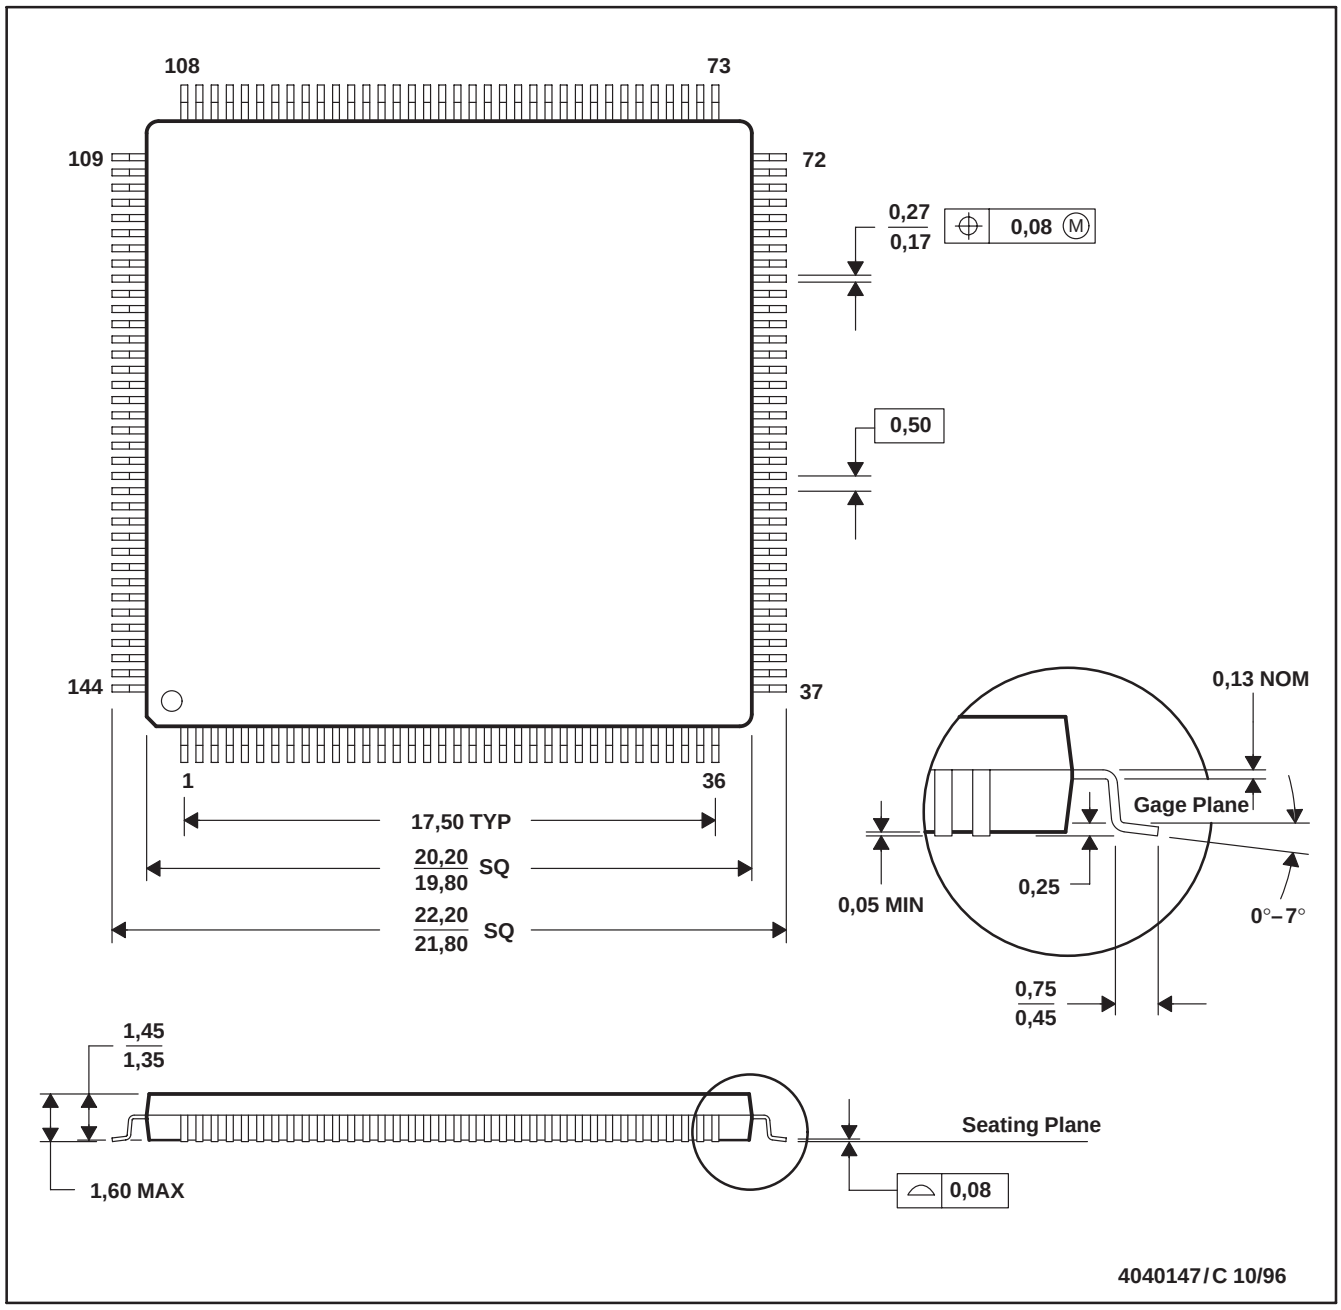
C. MicroStar BGA™ configuration

MicroStar BGA is a trademark of Texas Instruments Incorporated.

MTQF017A – OCTOBER 1994 – REVISED DECEMBER 1996

PGE (S-PQFP-G144) **PLASTIC QUAD FLATPACK**



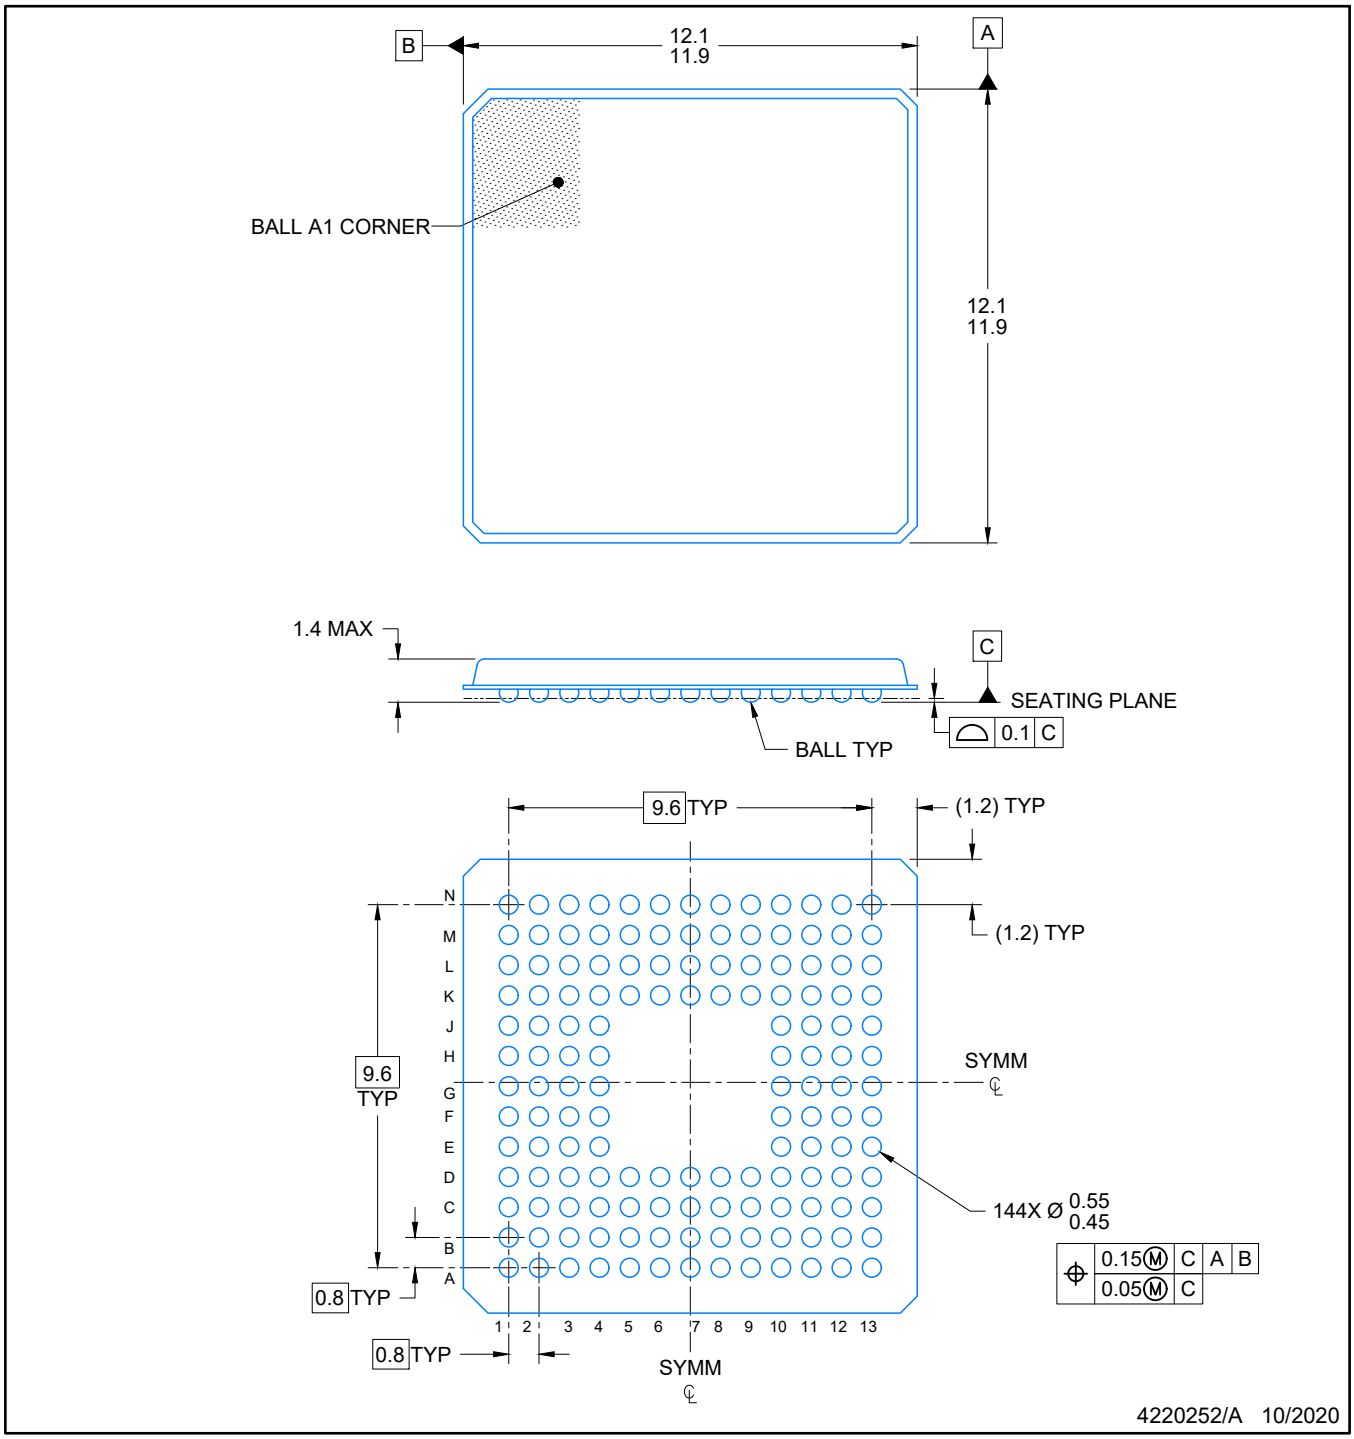
NOTES: A. All linear dimensions are in millimeters.
B. This drawing is subject to change without notice.
C. Falls within JEDEC MS-026

PACKAGE OUTLINE

ZGU0144A

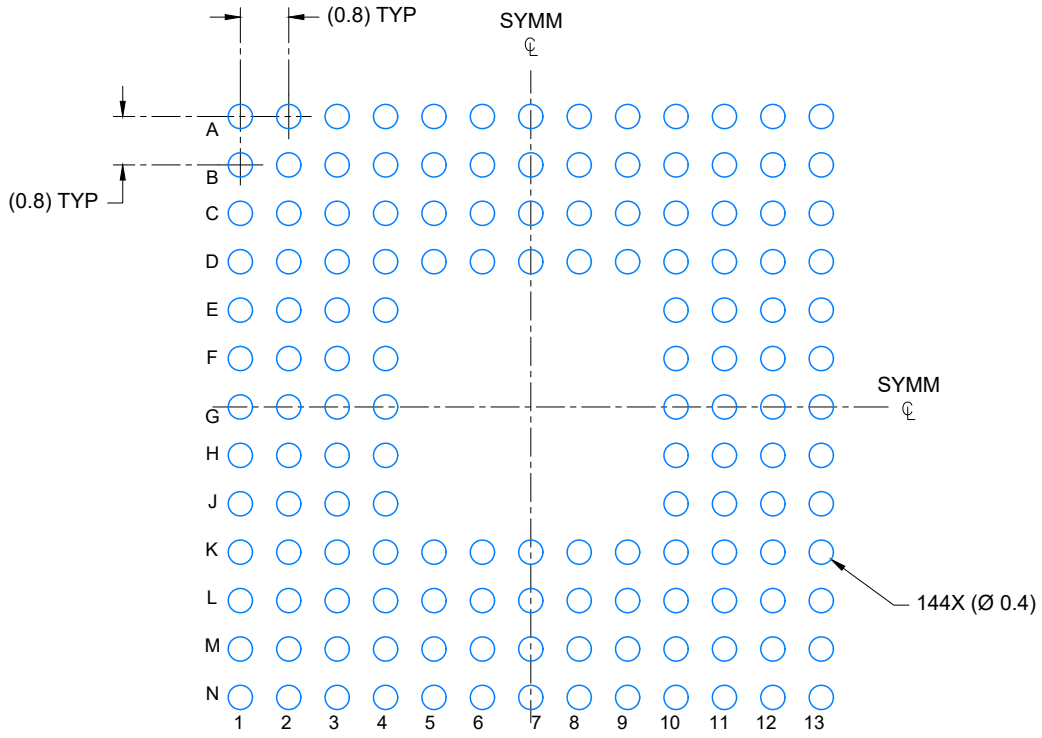
UBGA - 1.4 mm max height

PLASTIC BALL GRID ARRAY



NOTES:

1. All linear dimensions are in millimeters. Any dimensions in parenthesis are for reference only. Dimensioning and tolerancing per ASME Y14.5M.
2. This drawing is subject to change without notice.
3. This is a Pb-Free ball design.



LAND PATTERN EXAMPLE
SCALE: 8X
