

# DRV10983-Q1 Automotive, Three-Phase, Sensorless BLDC Motor Driver

## 1 Features

- Qualified for automotive applications
- AEC-Q100 qualified with the following results:
  - Device temperature grade 1: –40°C to 125°C ambient operating temperature range
  - Device HBM ESD classification level 1C
  - Device CDM ESD classification level C4A
- Operation voltage range:
  - Motor operation, 6.2 V to 28 V
  - Register setting preserved, 4.5 V to 45 V
- Supports load dump voltage up to 45 V
- Total driver H + L  $r_{DS(on)}$ 
  - 250 mΩ at  $T_A = 25^\circ\text{C}$
  - 325 mΩ at  $T_A = 125^\circ\text{C}$
- Drive current: 2-A continuous winding current (3-A Peak)
- Configurable output PWM slew rate and frequency for EMI management
- Sensorless proprietary Back Electromotive Force (BEMF) control scheme (no need of hall sensors)
- Continuous sinusoidal 180° commutation
- Initial position-detect algorithm to avoid back spin during start-up
- No external sense resistor required
- Flexible user interface options:
  - I<sup>2</sup>C interface: access registers for command and feedback
  - Dedicated SPEED pin: accepts either analog or PWM input
  - Dedicated FG pin: provides TACH feedback
  - Spin-up profile can be customized with EEPROM
  - Forward-reverse control with DIR pin
- Integrated buck converter to efficiently provide 5-V and 3.3-V LDOs for internal and external circuits
- Supply current 8.5 mA with standby version (DRV10983SQ)
- Supply current of 48 μA with sleep version (DRV10983Q)
- Protection features
  - Overcurrent protection (protection for phase-to-phase, phase-to-GND and phase-to- $V_{CC}$  shorts)
  - Lock detection
  - Anti-Voltage Surge (AVS) protection
  - UVLO protection

– Thermal shutdown protection

- Thermally enhanced package

## 2 Applications

- Small automotive pumps and fans
- Seat ventilation fans
- Motorcycle fuel pumps
- HEV battery cooling fans

## 3 Description

The DRV10983-Q1 device is a 3-phase sensorless motor driver with integrated power MOSFETs, which can provide continuous drive current up to 2 A. The device is specifically designed for cost-sensitive, low-noise, low-external-component-count fan and pump applications.

The DRV10983-Q1 device preserves register setting down to 4.5 V and delivers current to the motor with supply voltage as low as 6.2 V. If the power supply voltage is higher than 28 V, the device stops driving the motor and protects the DRV10983-Q1 circuitry. This function is able to handle a load dump condition up to 45 V.

TI provides [DRV10983-Q1 tuning Guide](#) for quick setup and tuning of the device for optimal performance.

### Device Options:

- DRV10983Q: Sleep Version
- DRV10983SQ: Standby Version

### Device Information <sup>(1)</sup>

| PART NUMBER | PACKAGE     | BODY SIZE (NOM)   |
|-------------|-------------|-------------------|
| DRV10983-Q1 | HTSSOP (24) | 7.80 mm × 6.40 mm |

(1) For all available packages, see the orderable addendum at the end of the data sheet.

## 4 Revision History

| Changes from Original (June 2017) to Revision A                                                                                              | Page      |
|----------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| • Updated timing information for entering and exiting sleep mode and standby mode .....                                                      | <b>8</b>  |
| • Added Analog and PWM mode timing diagrams.....                                                                                             | <b>10</b> |
| • Updated naming convention in <i>Step-Down Regulator</i> subsection .....                                                                   | <b>14</b> |
| • Changed the <i>Conditions to Enter or Exit Sleep or Standby Condition</i> table to reflect Electrical Characteristics parameter names..... | <b>18</b> |
| • Added Speed pin note to <a href="#">Table 1</a> .....                                                                                      | <b>19</b> |
| • Added subsection, <i>Required Sequence to Enter Sleep Mode</i> .....                                                                       | <b>19</b> |
| • Changed <a href="#">Figure 13</a> and <a href="#">Figure 14</a> .....                                                                      | <b>21</b> |
| • Changed <a href="#">Table 4</a> .....                                                                                                      | <b>24</b> |
| • Updated <i>Inductive AVS Function</i> subsection .....                                                                                     | <b>41</b> |
| • Changed eeWRnEn field description to properly reflect actual function .....                                                                | <b>55</b> |
| • Changed BEMF comparator hysteresis to reflect <i>Electrical Characteristics</i> specifications .....                                       | <b>58</b> |
| • Changed <a href="#">Table 36</a> .....                                                                                                     | <b>65</b> |
| • Added EEprom note to <a href="#">Layout Guidelines</a> .....                                                                               | <b>67</b> |

## 5 Description (Continued)

The DRV10983-Q1 device uses a proprietary sensorless control scheme to provide continuous sinusoidal drive, which significantly reduces the pure tone acoustics that typically occur as a result of commutation. The interface to the device is designed to be simple and flexible. The motor can be controlled directly through PWM, analog, or I<sup>2</sup>C inputs. Motor speed feedback is available through both the FG pin and the I<sup>2</sup>C interface simultaneously.

The DRV10983-Q1 device features an integrated buck regulator to step down the supply voltage efficiently to 5 V for powering both internal and external circuits. The 3.3-V LDO also may be used to provide power for external circuits. The device is available in either a sleep mode or a standby mode version to conserve power when the motor is not running. The standby mode (8.5 mA) version (DRV10983SQ) leaves the regulator running and the sleep mode (48 µA) version (DRV10983Q) shuts the regulator off. Use the standby mode version in applications where the regulator is used to power an external microcontroller. Throughout this data sheet, the DRV10983-Q1 part number is used for both devices for example DRV10983Q (sleep version) and DRV10983SQ (standby version), except for specific discussions of sleep vs standby functionality.

An I<sup>2</sup>C interface allows the user to reprogram specific motor parameters in registers and to program the EEPROM to help optimize the performance for a given application. The DRV10983-Q1 device is available in a thermally-efficient HTSSOP, 24-pin package with an exposed thermal pad. The operating ambient temperature is specified from –40°C to 125°C.

## 6 Pin Configuration and Functions

## Pin Functions

| T <sub>J_MAX</sub>            | Maximum junction temperature                                          | –40  | 150                 | °C   |
| T <sub>stg</sub>              | Storage temperature                                                   | –55  | 150                 | °C   |

- (1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
- (2) All voltage values are with respect to the ground terminal (GND) unless otherwise noted.

### 7.2 ESD Ratings

|                    |                         |                                                                   | VALUE | UNIT |
|--------------------|-------------------------|-------------------------------------------------------------------|-------|------|
| V <sub>(ESD)</sub> | Electrostatic discharge | Human body model (HBM), per AEC Q100-002, all pins <sup>(1)</sup> | ±2000 | V    |
|                    |                         | Charged device model (CDM), per AEC Q100-011, all pins            | ±750  |      |

- (1) AEC Q100-002 indicates that HBM stressing shall be in accordance with the ANSI/ESDA/JEDEC JS-001 specification.

### 7.3 Recommended Operating Conditions

|                |                                                                      | MIN  | NOM | MAX                 | UNIT |
|----------------|----------------------------------------------------------------------|------|-----|---------------------|------|
| Supply voltage | V <sub>CC</sub> , register contents preserved                        | 4.5  | 12  | 45                  | V    |
|                | V <sub>CC</sub> , motor operational                                  | 6.2  | 12  | 28                  |      |
| Voltage range  | U, V, W                                                              | –0.7 |     | 29                  | V    |

## 8 Detailed Description

### 8.1 Overview

The DRV10983-Q1 device is a three-phase sensorless motor driver with integrated power MOSFETs that provides drive-current capability up to 2 A continuously. The device is specifically designed for low-noise, low-external-component-count motor-drive applications. The device is configurable through a simple I<sup>2</sup>C interface to accommodate different motor parameters and spin-up profiles for different customer applications.

A 180° sensorless control scheme provides continuous sinusoidal output voltages to the motor phases to enable ultra-quiet motor operation by keeping the electrically induced torque ripple small.

The DRV10983-Q1 device features extensive protection and fault-detection mechanisms to ensure reliable operation. Voltage surge protection prevents the input V<sub>CC</sub> capacitor from overcharging, which is typical during motor deceleration. The device provides overcurrent protection without the need for an external current-sense resistor. Rotor-lock detection is available through several methods. These methods can be configured with register settings to ensure reliable operation. The device provides additional protection for undervoltage lockout (UVLO) and for thermal shutdown.

The commutation control algorithm continuously measures the motor phase current and periodically measures the V<sub>CC</sub> supply voltage. The device uses this information for BEMF estimation, and the information is also provided through the I<sup>2</sup>C register interface for debug and diagnostic use in the system, if desired.

A buck step-down regulator efficiently steps down the supply voltage. The output of this regulator provides power for the internal circuits and can also be used to provide power for an external circuit such as a microcontroller. If providing power for an external circuit is not necessary (and to reduce system cost), configure the buck step-down regulator as a linear regulator by replacing the inductor with a resistor.

The DRV10983-Q1 device has a flexible interface, capable of supporting both analog and digital inputs. In addition to the I<sup>2</sup>C interface, the device has FG, DIR, and SPEED pins. SPEED is the speed command input pin. DIR is the direction control input pin. FG is the speed indicator output, which shows the frequency of the motor commutation.

EEPROM is integrated in the DRV10983-Q1 device as memory for the motor parameter and operation settings. EEPROM data transfers to the registers after power-on and exit from sleep mode.

The DRV10983-Q1 device can also operate in register mode. If the system includes a microcontroller communicating through the I<sup>2</sup>C interface, the device can dynamically update the motor parameters and operation settings by writing to the registers. In this configuration, the EEPROM data is bypassed by the register settings.

## 8.3 Feature Description

### 8.3.1 Regulators

#### 8.3.1.1 Step-Down Regulator

The DRV10983-Q1 device includes a step-down hysteretic voltage regulator that can be operated as either a switching buck regulator using an external inductor or as a linear regulator using an external resistor. The best efficiency is achieved when the step-down regulator is in buck mode (see [Figure 7](#)). The regulator output voltage is 5 V. When the regulated voltage drops by the hysteresis level, the high-side FET turns on to raise the regulated voltage back to the target of 5 V. The switching frequency of the hysteretic regulator is not constant and changes with load.

If the step-down regulator is configured in buck mode, see  $I_{REG\_MAX\_L}$  in [Electrical Characteristics](#) to determine the amount of current provided for external load. If the step-down regulator is configured in linear mode, see  $I_{REG\_MAX\_R}$  in [Electrical Characteristics](#) to determine the amount of current provided for external load. Active current  $I_{CC}$  is higher in buck mode compared to linear mode.

### 8.3.1.2 3.3-V and 1.8-V LDO

The DRV10983-Q1 device includes a 3.3-V LDO and a 1.8-V LDO. The 3.3-V LDO is powered by Vreg and 1.8-V LDO is powered by 3.3-V LDO. The 1.8-V LDO is for internal circuits only. The 3.3-V LDO is mainly for internal circuits, but can also drive external loads not to exceed  $I_{V3P3\_MAX}$ . For example, it can work as a pullup voltage for the FG, DIR, SDA, and SCL interface.

Both the V1P8 and V3P3 capacitors must be connected to GND.

## 8.3.2 Protection Circuits

### 8.3.2.1 Thermal Shutdown

The DRV10983-Q1 device has a built-in thermal shutdown function, which shuts down the device when the junction temperature is more than  $T_{SDN}$ °C and recovers operating conditions when the junction temperature falls to  $T_{SDN} - T_{SDN\_HYS}$ °C.

The OverTemp status bit (address 0x00, bit 15) is set during thermal shutdown. In addition to the thermal shutdown function there is a warning bit that is set whenever the device exceeds  $T_{WARN}$  and is indicated by the TempWarning bit of the FaultReg register (address 0x00, bit 14).

### 8.3.2.2 Undervoltage Lockout (UVLO)

The DRV10983-Q1 device has a built-in UVLO function block. The device is locked out when  $V_{CC}$  is below  $V_{UVLO\_F}$  and is unlocked when  $V_{CC}$  is above  $V_{UVLO\_R}$ . The hysteresis of the UVLO threshold is  $V_{UVLO\_HYS}$ . In addition to the main supply, the step-down regulator, charge pump, and 3.3-V LDO all have undervoltage lockout monitors.

### 8.3.2.3 Overcurrent Protection

The overcurrent protection function acts to protect the device if the current, as measured from the FETs, exceeds the  $I_{OC\_limit}$  threshold. It protects the device in the event of a short-circuit condition on the motor phases. This includes phase shorts to GND, phase shorts to phase, or phase shorts to  $V_{CC}$ . The DRV10983-Q1 device places the output drivers into a high-impedance state until the lock time  $t_{LOCK\_OFF}$  has expired. The OverCurr status bit of the FaultReg register (address 0x00, bit 11) is set.

The DRV10983-Q1 device also provides acceleration current-limit and lock-detection current-limit functions to protect the device and motor (see [Current Limit](#) and [Lock Detect and Fault Handling](#)).

## Feature Description (continued)

### 8.3.2.4 Lock

When the motor is blocked or stopped by an external force, lock protection is triggered, and the device stops driving the motor immediately. After the lock release time  $t_{LOCK\_OFF}$ , the DRV10983-Q1 device resumes driving the motor again. If the lock condition is still present, it enters the next lock protection cycle, and repeats until the lock condition is removed. With this lock protection, the motor and device do not overheat or become damaged due to the motor being locked (see [Lock Detect and Fault Handling](#) ).

During a lock condition the Status register indicates which of the locks has occurred.

### 8.3.3 Motor Speed Control

The DRV10983-Q1 device offers four methods for indirectly controlling the speed of the motor by adjusting the output voltage amplitude. This can be accomplished by varying the supply voltage ( $V_{CC}$ ) or by controlling the speed command. The speed command can be controlled in one of three ways. The user can set the speed command by adjusting either the PWM input (PWM in) or the analog input (Analog) or by writing the speed command directly through the I<sup>2</sup>C serial port (I<sup>2</sup>C). The speed command is used to determine the PWM duty cycle output (PWM\_DCO) (see [Figure 9](#)).

The input PWM input (PWM in) can have a minimum duty cycle limit applied. DutyCycleLimit[1:0], accessible through the I<sup>2</sup>C interface, allows the user to configure the minimum duty cycle behavior. This behavior is illustrated in [Figure 8](#).

**Figure 8. Duty Cycle Profile**

The speed command may not always be equal to the PWM\_DCO because the DRV10983-Q1 device has the AVS function (see [Anti Voltage Suppression Function](#)), the acceleration current-limit function (see [Acceleration Current Limit](#)), and the closed-loop accelerate function (see [Closed-Loop Accelerate](#)) to optimize the control performance. These functions can limit the PWM\_DCO, which affects the output amplitude (see [Figure 9](#)).

## Feature Description (continued)

**Figure 9. Multiplexing the Speed Command to the Output Amplitude Applied to the Motor**

The output voltage amplitude applied to the motor is developed through sine wave modulation so that the phase-to-phase voltage is sinusoidal.

When any phase is measured with respect to ground, the waveform is sinusoidally coupled with third-order harmonics. This encoding technique permits one phase to be held at ground while the other two phases are pulse-width modulated. Figure 10 and Figure 11 show the sinusoidal encoding technique used in the DRV10983-Q1 device.

**Figure 10. PWM Output and the Average Value**

Sinusoidal voltage from phase to phase

Sinusoidal voltage with third-order harmonics from phase to GND

**Figure 11. Representing Sinusoidal Voltages With Third-Order Harmonic Output**

The output amplitude is determined by the magnitude of  $V_{CC}$  and the PWM duty cycle output (PWM\_DCO). The PWM\_DCO represents the peak duty cycle that is applied in one electrical cycle. The maximum amplitude is reached when PWM\_DCO is at 100%. The peak output amplitude is  $V_{CC}$ . When the PWM\_DCO is at 50%, the peak amplitude is  $V_{CC} / 2$  (see Figure 12).

## Feature Description (continued)

**Figure 12. Output Voltage Amplitude Adjustment**

Motor speed is controlled indirectly by controlling the output amplitude, which is achieved by either controlling  $V_{CC}$ , or controlling the PWM\_DCO. The DRV10983-Q1 device provides different options for the user to control the PWM\_DCO:

- Analog input (SPEED pin)
- PWM encoded digital input (SPEED pin)
- I<sup>2</sup>C serial interface.

See the [Closed Loop](#) section for more information.

### 8.3.4 Load Dump Handling

The recommended operation voltage of the DRV10983-Q1 device is from 6.2 V to 28 V. The device is able to drive the motor within this  $V_{CC}$  range.

In the load dump condition,  $V_{CC}$  can rise up to 45 V. Once the DRV10983-Q1 device detects that  $V_{CC}$  is higher than  $V_{OV\_R}$ , it stops driving the motor and protects its own circuitry. When  $V_{CC}$  drops below  $V_{OV\_F}$ , the DRV10983-Q1 device continues to operate the motor based on the user's command.

### 8.3.5 Sleep or Standby Condition

The DRV10983-Q1 device is available in either a sleep mode (DRV10983Q) or standby mode version (DRV10983SQ). The DRV10983-Q1 device enters either sleep or standby to conserve energy. When the device enters either sleep or standby, the device stops driving the motor. The step-down regulator is disabled in the sleep mode version to conserve more energy. The I<sup>2</sup>C interface is disabled and any register data not stored in EEPROM is reset for the sleep mode version. The step-down regulator remains active in the standby mode version. The register data is maintained, and the I<sup>2</sup>C interface remains active for standby mode version.

For different speed command modes, shows the timing and command to enter the sleep or standby condition.

**Table 1. Conditions to Enter or Exit Sleep or Standby Condition**

| SPEED COMMAND MODE | ENTER STANDBY CONDITION                                   | ENTER SLEEP CONDITION                                                     | EXIT FROM STANDBY CONDITION                                  | EXIT FROM SLEEP CONDITION                                                                                                                     |
|--------------------|-----------------------------------------------------------|---------------------------------------------------------------------------|--------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| Analog             | SPEED pin voltage < $V_{EN\_SB}$ for $t_{EN\_SB\_ANA}$    | SPEED pin voltage < $V_{EN\_SL}$ for $t_{EN\_SL\_ANA}$                    | SPEED pin voltage > $V_{EX\_SB}$ for $t_{EX\_SB\_ANA}$       | SPEED pin voltage > $V_{EX\_SL}$ for $t_{EX\_SL\_ANA}$                                                                                        |
| PWM                | SPEED pin low ( $V < V_{DIG\_IL}$ ) for $t_{EN\_SB\_PWM}$ | SPEED pin low ( $V < V_{DIG\_IL}$ ) for $t_{EN\_SL\_PWM}$                 | SPEED pin high ( $V > V_{DIG\_IH}$ ) for $t_{EX\_SB\_PWM}$   | SPEED pin high ( $V > V_{DIG\_IH}$ ) for $t_{EX\_SL\_PWM}$                                                                                    |
| I <sup>2</sup> C   | SpdCtrl[8:0] is programmed as 0 for $t_{EN\_SB\_PWM}$     | See <a href="#">Required Sequence to Enter Sleep Mode</a> Changed Table 4 | SpdCtrl[8:0] is programmed as non-zero for $t_{EX\_SB\_PWM}$ | SPEED pin high ( $V > V_{DIG\_IH}$ ) for $t_{EX\_SL\_PWM}$ (PWM mode) or SPEED pin voltage > $V_{EX\_SL}$ for $t_{EX\_SL\_ANA}$ (Analog mode) |

Speed pin in DRV10983SQ (Standby version) and DRV10983Q (sleep version) should be in known state (pulled high or low) when the speed is controlled via I<sup>2</sup>C.

Note that when using the analog speed command, a higher voltage is required to exit from the sleep condition than from the standby condition. The I<sup>2</sup>C speed command cannot take the device out of the sleep condition because I<sup>2</sup>C communication is disabled during the sleep condition.

**Table 2. Minimum PWM Duty Cycle Requirement for Different PWM Frequency to Exit Sleep Condition**

| INPUT PWM FREQUENCY (kHz) | PWM DUTY CYCLE (%) |
|---------------------------|--------------------|
| 0.1 to 0.5                | 14                 |
| 0.5 to 1                  | 11                 |
| 1 to 50                   | 9                  |
| 50 to 100                 | 4                  |
| 100                       | 3.5                |

### 8.3.5.1 Required Sequence to Enter Sleep Mode

In I<sup>2</sup>C speed command mode, either of two sequence options can be used to enter sleep mode.

#### 8.3.5.1.1 Option 1

1. Provide a non-zero value to the speed control register. For example, write 100 to register 0x30, speedCtrl[8:0].
2. Set the I<sup>2</sup>C OverRide bit to 1. That is, write 1 to register 0x30, speedCtrl[15].
3. In analog mode, be sure SPEED pin voltage is less than  $V_{EN\_SL}$  for  $t_{EN\_SL\_ANA}$ . In PWM mode, make sure SPEED pin is low ( $V < V_{DIG\_IL}$ ) for  $t_{EN\_SL\_PWM}$ .
4. Provide the value of zero to the speed control register to enter sleep mode. That is, write 0 to register 0x30, speedCtrl[8:0].

#### 8.3.5.1.2 Option 2

1. Set the motor disable bit to 1. That is, write 1 to register 0x60, EECtrl[15].
2. Set the I<sup>2</sup>C OverRide bit to 1. That is, write 1 to register 0x30, speedCtrl[15].
3. Set the motor disable bit to 0. That is, write 0 to register 0x60, EECtrl[15].
4. Provide the value of zero to the speed control register to enter sleep mode. That is, write 0 to register 0x30, speedCtrl[8:0].

### 8.3.6 EEPROM Access

The DRV10983-Q1 device has 112 bits (7 registers with 16-bit width) of EEPROM data, which are used to program the motor parameters as described in the [I<sup>2</sup>C Serial Interface](#).

The procedure for programming the EEPROM is as follows. TI recommends to perform the EEPROM programming without the motor spinning, cycle the power after the EEPROM write, and read back the EEPROM to verify the programming is successful.

1. Power up with any voltage within operating voltage range (6.2 V to 28 V)
2. (DRV10983Q only) Exit from sleep condition
3. Wait 10 ms
4. Write register 0x60 to set MTR\_DIS = 1; this disables the motor driver.
5. Write register 0x31 with 0x0000 to clear the EEPROM access code
6. Write register 0x31 with 0xC0DE to enable access to EEPROM
7. Read register 0x32 for eeReadyStatus = 1
8. Case-A: Mass Write
  - A. Write all individual shadow registers
    - a. Write register 0x90 (CONFIG1) with CONFIG1 data
    - b. ...

- c. Write register 0x96 (CONFIG7) with CONFIG7 data
  - B. Write the following to register 0x35
    - a. ShadowRegEn = 0
    - b. eeRefresh = 0
    - c. eeWRnEn = 1
    - d. EEPROM Access Mode = 10
  - C. Wait for register 0x32 eeReadyStatus = 1 – EEPROM is now updated with the contents of the shadow registers.
- 9. Case-B: Mass Read
  - A. Write the following to register 0x35
    - a. ShadowRegEn = 0
    - b. eeRefresh = 0
    - c. eeWRnEn = 0
    - d. eeAccMode = 10
  - B. Internally, the device starts reading the EEPROM and storing it in the shadow registers.
  - C. Wait for register 0x32 eeReadyStatus = 1 – shadow registers now contain the EEPROM values
- 10. Write register 0x60 to set MTR\_DIS = 0; this re-enables the motor driver

## 8.4 Device Functional Modes

This section includes the logic required to be able to reliably start and drive the motor. It describes the processes used in the logic core and provides the information needed to configure the parameters effectively to work over a wide range of applications.

### 8.4.1 Motor Parameters

See the [DRV10983-Q1 Tuning Guide](#) for the motor parameter measurement.

The motor phase resistance and BEMF constants are two important parameters used to characterize a BLDC motor. The DRV10983-Q1 device requires these parameters to be configured in the register. The motor phase resistance is programmed by writing the values for  $R_{m[6:0]}$  (combination of  $RM_{Shift[2:0]}$  and  $RM_{Value[3:0]}$ ) in the Config1 register. The BEMF constant is programmed by writing the values for  $K_t[6:0]$  (combination of  $KT_{Shift[2:0]}$  and  $KT_{Value[3:0]}$ ) in the Config2 register.

#### 8.4.1.1 Motor Phase Resistance

For a wye-connected motor, the motor phase resistance refers to the resistance from the phase output to the center tap,  $R_{PH\_CT}$  (denoted as  $R_{PH\_CT}$  in [Figure 13](#)).

**Figure 13. Wye-Connected Motor Phase Resistance**

For a delta-connected motor, the motor phase resistance refers to the equivalent phase to center tap in the wye configuration. In [Figure 14](#), it is denoted as  $R_Y$ .  $R_{PH\_CT} = R_Y$ .

For both the delta-connected motor and the wye-connected motor, the easy way to get the equivalent  $R_{PH\_CT}$  is to measure the resistance between two phase terminals ( $R_{PH\_PH}$ ), and then divide this value by two,  $R_{PH\_CT} = \frac{1}{2} R_{PH\_PH}$ .

**Figure 14. Delta-Connected Motor and the Equivalent Wye Connections**

## Device Functional Modes (continued)

The motor phase resistance ( $R_{PH\_CT}$ ) must be converted to a 7-bit digital register value  $Rm[6:0]$  to program the motor phase resistance value. The digital register value can be determined as follows:

1. Convert the motor phase resistance ( $R_{PH\_CT}$ ) to a digital value where the LSB is weighted to represent 9.67 mΩ:  $Rmdig = R_{PH\_CT} / 0.00967$ .
2. Encode the digital value such that  $Rmdig = RMValue[3:0] \ll RShift[2:0]$ .

The maximum resistor value,  $R_{PH\_CT}$ , that can be programmed for the DRV10983-Q1 device is 18.5 Ω, which represents  $Rmdig = 1920$  and an encoded  $Rm[6:0]$  value of 0x7Fh. The minimum resistor the DRV10983-Q1 device supports is 0.029 Ω,  $R_{PH\_CT}$ , which represents  $Rmdig = 3$ .

For convenience, the encoded value for  $Rm[6:0]$  can also be obtained from [Table 3](#).

**Table 3. Motor Phase Resistance Look-Up Table**

| RM[6:0] {RShift[2:0], RMValue[3:0]} |      | R <sub>PH_CT</sub> (Ω) | RM[6:0] {RShift[2:0], RMValue[3:0]} |      | R <sub>PH_CT</sub> (Ω) | RM[6:0] {RShift[2:0], RMValue[3:0]} |      | R <sub>PH_CT</sub> (Ω) |
|-------------------------------------|------|------------------------|-------------------------------------|------|------------------------|-------------------------------------|------|------------------------|
| BINARY                              | HEX  |                        | BINARY                              | HEX  |                        | BINARY                              | HEX  |                        |

### 8.4.1.2 BEMF Constant

The BEMF constant,  $K_t[6:0]$  describes the phase-to-phase BEMF voltage of the motor as a function of the motor velocity.

Figure 15 shows the measurement technique for this constant as used in the DRV10983-Q1 device.

**Figure 15.  $K_{t_{pH}}$  Definition**

With the motor coasting, use an oscilloscope to capture the differential voltage waveform between any two phases. Derive the BEMF constant used by the DRV10983-Q1 device as shown in Equation 1.

$$K_{t_{pH}} = E_p \times t_e$$

where

- $E_p$  is  $\frac{1}{2}$  the peak-to-peak amplitude of the measured voltage
  - $t_e$  is the electrical period
- (1)

The measured BEMF constant ( $K_{t_{pH}}$ ) must be converted to a 7-bit digital register value  $K_t[6:0]$  (combination of  $K_t\text{Shift}[2:0]$  and  $K_t\text{Value}[3:0]$ ) to program the BEMF constant value. The digital register value can be determined as follows:

1. Convert the measured  $K_{t_{pH}}$  to a weighted digital value:  $K_{t_{ph\_dig}} = 1090 \times K_{t_{pH}}$
2. Encode the digital value such that  $K_{t_{ph\_dig}} = K_t\text{Value}[3:0] \ll K_t\text{Shift}[2:0]$ .

The maximum  $K_{t_{pH}}$  that can be programmed is 1760 mV/Hz. This represents a digital value of 1920 and an encoded  $K_t[6:0]$  value of 0x7Fh. The minimum  $K_{t_{pH}}$  that can be programmed is 0.92 mV/Hz, which represents a digital value of 1 and an encoded  $K_t[6:0]$  value of 0x01h.

For convenience, the encoded value of  $K_t[6:0]$  may also be obtained from Table 4.

**Table 4. BEMF Constant Look-Up Table**

## 8.4.2 Starting the Motor Under Different Initial Conditions

The motor can be in one of three states when the DRV10983-Q1 device attempts to begin the start-up process. The motor may be stationary, or spinning in the forward or reverse directions. The DRV10983-Q1 device includes a number of features to allow for reliable motor start under all of these conditions. [Figure 16](#) shows the motor start-up flow for each of the three initial motor states.

### 8.4.2.1 Case 1 – Motor is Stationary

If the motor is stationary, the commutation logic must be initialized to be in phase with the position of the motor. The DRV10983-Q1 device provides for two options to initialize the commutation logic to the motor position. Initial position detect (IPD) determines the position of the motor based on the deterministic inductance variation, which is often present in BLDC motors. The *align-and-go* technique forces the motor into alignment by applying a voltage across a particular motor phase to force the motor to rotate in alignment with this phase.

### 8.4.2.2 Case 2 – Motor is Spinning in the Forward Direction

If the motor is spinning forward with enough velocity, the DRV10983-Q1 device may be configured to go directly into closed loop. By resynchronizing to the spinning motor, the user achieves the fastest possible start-up time for this initial condition.

### 8.4.2.3 Case 3 – Motor is Spinning in the Reverse Direction

If the motor is spinning in the reverse direction, the DRV10983-Q1 device provides several methods to convert it back to the forward direction.

One method, reverse drive, allows the motor to be driven so that it accelerates through zero velocity. The motor achieves the shortest possible spin-up time in systems where the motor is spinning in the reverse direction.

If this feature is not selected, then the DRV10983-Q1 device may be configured either to wait for the motor to stop spinning or to brake the motor. After the motor has stopped spinning, the motor start-up sequence proceeds as it would for a motor which is stationary.

Take care when using the reverse-drive or brake feature to ensure that the current is limited to an acceptable level and that the supply voltage does not surge as a result of energy being returned to the power supply.

**Figure 16. Start the Motor Under Different Initial Conditions**

### 8.4.3 Motor Start Sequence

Figure 17 shows the motor-start sequence implemented in the DRV10983-Q1 device.

**Figure 17. Motor Starting-Up Flow**

**Power-On State** This is the initial power-on state of the motor start sequencer (MSS). The MSS starts in this state on initial power-up or whenever the DRV10983-Q1 device comes out of either standby or sleep mode.

**ISDen Judgment** After power-on, the DRV10983-Q1 MSS enters the ISDen judgment where it checks to see if the initial speed detect (ISD) function is enabled (ISDen = 1). If ISD is disabled, the MSS proceeds directly to the BrkEn Judgment. If ISD is enabled, the motor start sequence advances to the ISD state.

**ISD State** The MSS determines the initial condition of the motor (see [Initial Speed Detect](#)).

**Speed<ISDThr Judgment** If the motor speed is lower than the threshold defined by ISDThr[1:0], then the motor is considered to be stationary and the MSS proceeds to the BrkEn judgment. If the speed is greater than the threshold defined by ISDThr[1:0], the start sequence proceeds to the Forward judgment.

**Forward Judgment** The MSS determines whether the motor is spinning in the forward or the reverse direction. If the motor is spinning in the forward direction, the DRV10983-Q1 device executes the resynchronization (see [Motor Resynchronization](#)) process by transitioning directly into the ClosedLoop state. If the motor is spinning in the reverse direction, the MSS proceeds to the

Speed>RvsDrThr.

**Speed>RvsDrThr Judgment** The motor start sequencer checks to see if the reverse speed is greater than the threshold defined by RvsDrThr[1:0]. If it is, then the MSS returns to the ISD state to allow the motor to decelerate. This prevents the DRV10983-Q1 device from attempting to reverse drive or brake a motor that is spinning too quickly. If the reverse speed of the motor is less than the threshold defined by RvsDrThr[1:0], then the MSS advances to the RvsDrEn judgment.

**RvsDrEn Judgment** The MSS checks to see if the reverse drive function is enabled (RvsDrEn = 1). If it is, the MSS transitions into the RvsDr state. If the reverse drive function is not enabled, the MSS advances to the BrkEn judgment.

**RvsDr State** The DRV10983-Q1 device drives the motor in the forward direction to force it to rapidly decelerate (see [Reverse Drive](#)). When it reaches zero velocity, the MSS transitions to the Accelerate state.

**BrkEn Judgment** The MSS checks to determine whether the brake function is enabled (BrkDoneThr[2:0] ≠ 000). If the brake function is enabled, the MSS advances to the brake state.

**Brake State** The device performs the brake function (see [Motor Brake](#)).

**Time>BrkDoneThr Judgment** The MSS applies brake for a time configured by BRKDoneThr[2:0]. After brake state, the MSS advances to the IPDEn judgment.

**IPDEn Judgment** The MSS checks to see if IPD has been enabled (IPDCurrThr[3:0] ≠ 0000). If the IPD is enabled, the MSS transitions to the IPD state. Otherwise, it transitions to the align state.

**Align State** The DRV10983-Q1 device performs the align function (see [Align](#)). After the align completes, the MSS transitions to the Accelerate state.

**IPD State** The DRV10983-Q1 device performs the IPD function. The IPD function is described in [Initial Position Detect \(IPD\)](#). After the IPD completes, the MSS transitions to the accelerate state.

**Accelerate State** The DRV10983-Q1 device accelerates the motor according to the settings of StAccel and StAccel2. After applying the accelerate settings, the MSS advances to the Speed>Op2ClsThr judgment.

**Speed>Op2ClsThr Judgment** The motor accelerates until the drive rate exceeds the threshold configured by the Op2ClsThr[4:0] settings. When this threshold is reached, the DRV10983-Q1 device enters into the ClosedLoop state.

**ClosedLoop State** In this state, the DRV10983-Q1 device drives the motor based on feedback from the commutation control algorithm.

**DIR Pin Change Judgment** If the DIR pin is changed during any of above states, DRV10983-Q1 device stops driving the motor and restarts from the beginning.

#### 8.4.3.1 Initial Speed Detect

The ISD function is used to identify the initial condition of the motor. If the function is disabled, the DRV10983-Q1 device does not perform the initial speed detect function and treats the motor as if it is stationary.

Phase-to-phase comparators are used to detect the zero crossings of the motor's BEMF voltage while it is coasting (motor phase outputs are in the high-impedance state). [Figure 18](#) shows the configuration of the comparators.

**Figure 18. Initial Speed Detect Function**

If the UW comparator output is lagging the UV comparator by 60°, the motor is spinning forward. If the UW comparator output is leading the UV comparator by 60°, the motor is spinning in reverse.

The motor speed is determined by measuring the time between two rising edges of either of the comparators.

If neither of the comparator outputs toggles for a given amount of time, the condition is defined as stationary. The amount of time can be programmed by setting the register bits ISDThr[1:0].

#### 8.4.3.2 Motor Resynchronization

The resynchronize function works when the ISD function is enabled and determines that the initial state of the motor is spinning in the forward direction. The speed and position information measured during ISD are used to initialize the drive state of the DRV10983-Q1 device, which can transition directly into the closed-loop running state without needing to stop the motor.

#### 8.4.3.3 Reverse Drive

The ISD function measures the initial speed and the initial position; the DRV10983-Q1 reverse drive function acts to reverse accelerate the motor through zero speed and to continue accelerating until the closed loop threshold is reached (see Figure 19). If the reverse speed is greater than the threshold configured in RvsDrThr[1:0], then the DRV10983-Q1 device waits until the motor coasts to a speed that is less than the threshold before driving the motor to reverse accelerate.

**Figure 19. Reverse Drive Function**

Reverse drive is suitable for applications where the load condition is light at low speed and relatively constant and where the reverse speed is low (that is, a fan motor with little friction). For other load conditions, the motor brake function provides a method for helping force a motor which is spinning in the reverse direction to stop spinning before a normal start-up sequence.

#### **8.4.3.4 Motor Brake**

The motor brake function can be used to stop the spinning motor before attempting to start the motor. The brake is applied by turning on all three of the low-side driver FETs.

Brake is enabled by configuring a non-zero BrkDoneThr[2:0]. Brake is applied for a time configured by BrkDoneThr[2:0] (forward or reverse). After the motor is stopped, the motor position is unknown. To proceed with restarting in the correct direction, the IPD or align-and-go algorithm must be implemented. The motor start sequence is the same as it would be for a motor starting in the stationary condition.

The motor brake function can be disabled. The motor skips the brake state and attempts to spin the motor as if it were stationary. If this happens while the motor is spinning in either direction, the start-up sequence may not be successful.

#### **8.4.3.5 Motor Initialization**

##### **8.4.3.5.1 Align**

The DRV10983-Q1 device aligns a motor by injecting dc current through a particular phase pattern which is current flowing into phase V, flowing out from phase W for a certain time (configured by AlignTime[2:0]). The current magnitude is determined by OpenLCurr[1:0]. The motor should be aligned at the known position.

The time of align affects the start-up timing (see [Start-Up Timing](#)). A bigger-inertia motor requires longer align time.

##### **8.4.3.5.2 Initial Position Detect (IPD)**

The inductive sense method is used to determine the initial position of the motor when IPD is enabled. IPD is enabled by selecting IPDCurrThr[3:0] to any value other than 0000.

IPD can be used in applications where reverse rotation of the motor is unacceptable. Because IPD is not required to wait for the motor to align with the commutation, it can allow for a faster motor start sequence. IPD works well when the inductance of the motor varies as a function of position. Because it works by pulsing current to the motor, it can generate acoustics which must be taken into account when determining the best start method for a particular application.

##### **8.4.3.5.2.1 IPD Operation**

The IPD operates by sequentially applying voltage across two of the three motor phases according to the following sequence: VW WV UV VU WU UW (see [Figure 20](#)). When the current reaches the threshold configured in IPDCurrThr[3:0], the voltage across the motor is stopped. The DRV10983-Q1 device measures the time it takes from when the voltage is applied until the current threshold is reached. The time varies as a function of the inductance in the motor windings. The state with the shortest time represents the state with the minimum inductance. The minimum inductance is because of the alignment of the north pole of the motor with this particular driving state.

Permanent Magnet Position ← Saturation Position of the Magnetic Field ← Smallest Inductance ← Minimum Time

**Figure 20. IPD Function**

#### 8.4.3.5.2.2 IPD Release Mode

Two options are available for stopping the voltage applied to the motor when the current threshold is reached. If  $IPDRIsMd = 0$ , the recirculate mode is selected. The low-side (S6) MOSFET remains on to allow the current to recirculate between the MOSFET (S6) and body diode (S2) (see [Figure 21](#)). If  $IPDRIsMd = 1$ , the high-impedance (Hi-Z) mode is selected. Both the high-side (S1) and low-side (S6) MOSFETs are turned off and the current flies back across the body diodes into the power supply (see [Figure 22](#)).

In the high-impedance state, the phase current has a faster settle-down time, but that could result in a surge on  $V_{CC}$ . Manage this with appropriate selection of either a clamp circuit or by providing sufficient capacitance between  $V_{CC}$  and GND. If the voltage surge cannot be contained and if it is unacceptable for the application, then select the recirculate mode. When selecting the recirculate mode, select the  $IPDClk[1:0]$  bits to give the current in the motor windings enough time to decay to 0.

**Figure 21. IPD Release Mode 0**

**Figure 22. IPD Release Mode 1**

#### 8.4.3.5.2.3 IPD Advance Angle

After the initial position is detected, the DRV10983-Q1 device begins driving the motor at an angle specified by IPDAdvAgl[1:0].

Advancing the drive angle anywhere from 0° to 180° results in positive torque. Advancing the drive angle by 90° results in maximum initial torque. Applying maximum initial torque could result in uneven acceleration to the rotor. Select the IPDAdvAgl[1:0] to allow for smooth acceleration in the application (see [Figure 23](#)).

**Figure 23. IPD Advance Angle**

#### 8.4.3.5.3 Motor Start

After it is determined that the motor is stationary and after completing the motor initialization with either align or IPD, the DRV10983-Q1 device begins to accelerate the motor. This acceleration is accomplished by applying a voltage determined by the open-loop current setting (OpenLCurr[1:0]) to the appropriate drive state and by increasing the rate of commutation without regard to the real position of the motor (referred to as open-loop operation). The function of the open-loop operation is to drive the motor to a minimum speed so that the motor generates sufficient BEMF to allow the commutation control logic to accurately drive the motor.

[Table 5](#) lists the configuration options that can be set in register to optimize the initial motor acceleration stage for different applications.

**Table 5. Configuration Options for Controlling Open-Loop Motor Start**

| DESCRIPTION                    | REG. NAME | CONFIGURATION BITS | MIN. VALUE               | MAX. VALUE           |
|--------------------------------|-----------|--------------------|--------------------------|----------------------|
| Open- to closed-loop threshold | CONFIG4   | Op2ClsThr[4:0]     | 0.8 Hz                   | 204.8 Hz             |
| Align time                     | CONFIG4   | AlignTime[2:0]     | 40 ms                    | 5.3 s                |
| First-order accelerate         | CONFIG4   | StAccel[2:0]       | 0.019 Hz/s               | 76 Hz/s              |
| Second-order accelerate        | CONFIG4   | StAccel2[2:0]      | 0.0026 Hz/s <sup>2</sup> | 57 Hz/s <sup>2</sup> |
| Open-loop current setting      | CONFIG3   | OpenLCurr[1:0]     | 200 mA                   | 1.6 A                |
| Align current setting          |           |                    | 150 mA                   | 1.2 A                |
| Open-loop current ramping      | CONFIG3   | OpLCurrRt[2:0]     | 0.023 V <sub>CC</sub> /s | 6 V <sub>CC</sub> /s |

#### 8.4.3.6 Start-Up Timing

Start-up timing is determined by the align and accelerate time. The align time can be set by AlignTime[2:0]. The accelerate time is defined by the open-to-closed loop threshold Op2ClsThr[4:0] along with the first-order StAccel[2:0](A1) and second-order StAccel2[2:0](A2) acceleration coefficients. Figure 24 shows the motor start-up process.

**Figure 24. Motor Start-Up Process**

Select the first-order and second-order acceleration coefficients to allow the motor to reliably accelerate from zero velocity up to the closed-loop threshold in the shortest time possible. Using a slow acceleration coefficient during the first order accelerate stage can help improve reliability in applications where it is difficult to accurately initialize the motor with either align or IPD.

Select the open-to-closed loop threshold to allow the motor to accelerate to a speed that generates sufficient BEMF for closed-loop control. This is determined by the velocity constant of the motor based on the relationship described in Equation 2.

$$\text{BEMF} = K_{t_{PH}} \times \text{speed (Hz)} \quad (2)$$

#### 8.4.4 Align Current

During the align state, the measured align current is dependent on actual motor phase resistance and  $r_{DS(on)}$  of the internal FETs. The relationship between measured align current and configured align current is derived from actual motor phase resistance, configured motor phase resistance and  $r_{DS(on)}$ .

$$\text{AlignCurrent\_Measured} = \text{AlignCurrent\_Configured} \times \left[ \frac{R_m}{R_{motor} + r_{DS(on)}} \right]$$

where

- AlignCurrent\_Measured is the actual align current measured during the align state
- AlignCurrent\_Configured is the align current configured by OpenLCurr[1:0]
- $R_{motor}$  is the actual motor phase resistance
- $r_{DS(on)}$  is the resistance between the drain and source of the FETs during the on-state
- $R_m$  is configured by Rm[6:0]

(3)

### 8.4.5 Start-Up Current Setting

The start-up current setting is to control the peak start-up during open loop. During open-loop operation, it is desirable to control the magnitude of drive current applied to the motor. This is helpful in controlling and optimizing the rate of acceleration. The limit takes effect during reverse drive, align, and acceleration.

The start current is set by programming the OpenLCurr[1:0] bits. The current should be selected to allow the motor to reliably accelerate to the handoff threshold. Heavier loads may require a higher current setting, but it should be noted that the rate of acceleration is limited by the acceleration rate (StAccel[2:0], StAccel2[2:0]). If the motor is started with more current than necessary to reliably reach the handoff threshold, it results in higher power consumption.

The start current is controlled based on the relationship shown in Equation 4 and Figure 25. The duty cycle applied to the motor is derived from the calculated value for  $U_{Limit}$  and the magnitude of the supply voltage,  $V_{CC}$ , as well as the drive state of the motor.

$$U_{Limit} = I_{Limit} \times R_m + \text{Speed (Hz)} \times K_t$$

where

- $I_{Limit}$  is configured by OpenLCurr[1:0]
- $R_m$  is configured by Rm[6:0]
- Speed is variable based motor's open loop acceleration profile
- $K_t$  is configured by Kt[6:0]

(4)

**Figure 25. Motor Start-Up Current**

#### 8.4.5.1 Start-Up Current Ramp-Up

A fast change in the applied drive current may result in a sudden change in the driving torque. In some applications, this could result in acoustic noise. To avoid this, the DRV10983-Q1 device allows the option of limiting the rate at which the current is applied to the motor. OpLCurrRt[2:0] sets the maximum voltage ramp-up rate that is applied to the motor. The waveforms in Figure 26 show how this feature can be used to gradually ramp the current applied to the motor.

**Figure 26. Motor Start-Up Current Ramp**

### 8.4.6 Closed Loop

In closed loop operation, the DRV10983-Q1 device continuously samples the current in the U phase of the motor and uses this information to estimate the BEMF voltage that is present. The drive state of the motor is controlled based on the estimated BEMF voltage.

### 8.4.6.1 Half-Cycle Control and Full-Cycle Control

The estimated BEMF used to control the drive state of the motor has two zero-crosses every electrical cycle. The DRV10983-Q1 device can be configured to update the drive state either once every electrical cycle or twice for every electrical cycle. When AdjMode is programmed to 1, half-cycle adjustment is applied. The control logic is triggered at both the rising edge and falling edge. When AdjMode is programmed to 0, full-cycle adjustment is applied. The control logic is triggered only at the rising edge (see Figure 27).

Half-cycle adjustment provides a faster response when compared with full-cycle adjustment. Use half-cycle adjustment whenever the application requires operation over large dynamic loading conditions. Use the full-cycle adjustment for low-current (<1 A) applications because it offers more tolerance for current-measurement offset errors.

**Figure 27. Closed-Loop Control Commutation-Adjustment Mode**

### 8.4.6.2 Analog-Mode Speed Control

The SPEED input pin can be configured to operate as an analog input (SpdCtrlMd = 0).

When configured for analog mode, the voltage range on the SPEED pin can be varied from 0 to V<sub>3P3</sub>. If SPEED > V<sub>ANA\_FS</sub>, the speed command is maximum. If V<sub>ANA\_ZS</sub> ≤ SPEED < V<sub>ANA\_FS</sub> the speed command changes linearly according to the magnitude of the voltage applied at the SPEED pin. If SPEED < V<sub>ANA\_ZS</sub> the speed command is to stop the motor. Figure 28 shows the speed command when operating in analog mode.

**Figure 28. Analog-Mode Speed Command**

### 8.4.6.3 Digital PWM-Input-Mode Speed Control

If SpdCtrlMd = 1, the SPEED input pin is configured to operate as a PWM-encoded digital input. The PWM duty cycle applied to the SPEED pin can be varied from 0 to 100%. The speed command is proportional to the PWM input duty cycle. The speed command stops the motor when the PWM input keeps at 0 for t<sub>EN\_SL\_SB</sub> (see Figure 29).

The frequency of the PWM input signal applied to the SPEED pin is defined as f<sub>PWM</sub>. This is the frequency the device can accept to control motor speed. It does not correspond to the PWM output frequency that is applied to the motor phase. The PWM output frequency can be configured to be either 25 kHz when the PWMFreq bit is set to 0 or to 50 kHz when PWMFreq bit is set to 1.

Figure 29. PWM-Mode Speed Command

#### 8.4.6.4 I<sup>2</sup>C-Mode Speed Control

The DRV10983-Q1 device can also command the speed through the I<sup>2</sup>C serial interface. To enable this feature, the OverRide bit is set to 1. When the DRV10983-Q1 device is configured to operate in I<sup>2</sup>C mode, it ignores the signal applied to the SPEED pin.

The speed command can be set by writing the SpdCtrl[8:0] bits. The 9-bit SpdCtrl [8:0] located in the SpeedCtrl registers is used to set the peak amplitude voltage applied to the motor. The maximum speed command is set when SpdCtrl [8:0] is set to 0x1FF (511).

#### 8.4.6.5 Closed-Loop Accelerate

To prevent sudden changes in the torque applied to the motor which could result in acoustic noise, the DRV10983-Q1 device provides the option of limiting the maximum rate at which the speed command changes. CIsLpAccel[2:0] can be programmed to set the maximum rate at which the speed command changes (shown in Figure 30).

Figure 30. Closed Loop Accelerate

#### 8.4.6.6 Control Coefficient

The DRV10983-Q1 device continuously measures the motor current and uses this information to control the drive state of the motor when operating in closed-loop mode. In applications where noise makes it difficult to control the commutation optimally, the CtrlCoef[1:0] can be used to attenuate the feedback used for closed-loop control. The loop is less reactive to the noise on the feedback and provides for a smoother output.

#### 8.4.6.7 Commutation Control Advance Angle

To achieve the best efficiency, it is often desirable to control the drive state of the motor so that the motor phase current is aligned with the motor BEMF voltage.

To align the motor phase current with the motor BEMF voltage, consider the inductive effect of the motor. The voltage applied to the motor should be applied in advance of the motor BEMF voltage (see Figure 31). The DRV10983-Q1 device provides configuration bits for controlling the time ( $t_{adv}$ ) between the driving voltage and BEMF.

For motors with salient pole structures, aligning the motor BEMF voltage with the motor current may not achieve the best efficiency. In these applications, the timing advance should be adjusted accordingly. Accomplish this by operating the system at constant speed and load conditions and by adjusting  $t_{adv}$  until the minimum current is achieved.

**Figure 31. Advance Time ( $t_{adv}$ ) Definition**

The DRV10983-Q1 device has two options for adjusting the motor commutate advance time. When CommAdvMode = 0, mode 0 is selected. When CommAdvMode = 1, mode 1 is selected.

Mode 0:  $t_{adv}$  is maintained to be a fixed time relative to the estimated BEMF zero cross as determined by Equation 5.

$$t_{adv} = t_{SETTING} \quad (5)$$

Mode 1:  $t_{adv}$  is maintained to be a variable time relative to the estimated BEMF zero cross as determined by Equation 6.

$$t_{adv} = t_{SETTING} \times (U - BEMF) / U.$$

where

- U is the phase voltage amplitude
- BEMF is phase BEMF amplitude

$t_{SETTING}$  (in  $\mu s$ ) is determined by the configuration of the TCtrlAdvShift [2:0] and TCtrlAdvValue [3:0] bits as defined in Equation 7. For convenience, the available  $t_{SETTING}$  values are provided in Table 6.

$$t_{SETTING} = 2.5 \mu s \times [TCtrlAdvValue[3:0]] \ll TCtrlAdvShift[2:0] \quad (7)$$

**Table 6. Configuring Commutation Advance Timing by Adjusting  $t_{\text{SETTING}}$** 

| TCtrlAdv [6:0]<br>{TCtrlAdvShift[2:0],<br>TCtrlAdvValue[3:0]} |      | $t_{\text{SETTING}}$ (μs) | TCtrlAdv [6:0]<br>{TCtrlAdvShift[2:0],<br>TCtrlAdvValue[3:0]} |      | $t_{\text{SETTING}}$ (μs) | TCtrlAdv [6:0]<br>{TCtrlAdvShift[2:0],<br>TCtrlAdvValue[3:0]} |      | $t_{\text{SETTING}}$ (μs) |

### 8.4.7 Current Limit

The DRV10983-Q1 device has several current-limit modes to help ensure optimal control of the motor and to ensure safe operation. The various current-limit modes are listed in [Table 7](#). Acceleration current limit is used to provide a means of controlling the amount of current delivered to the motor. This is useful when the system needs to limit the amount of current pulled from the power supply during motor start-up. The lock-detection current limit is a configurable threshold that can be used to limit the current applied to the motor. Overcurrent protection is used to protect the device; therefore, it cannot be disabled or configured to a different threshold. The current-limit modes are described in the following sections.

**Table 7. DRV10983-Q1 Current-Limit Modes**

| CURRENT LIMIT MODE           | SITUATION     | ACTION                                          | FAULT DIAGNOSIS           |
|------------------------------|---------------|-------------------------------------------------|---------------------------|
| Acceleration current limit   | Motor start   | Limit the output voltage amplitude              | No fault                  |
| Lock-detection current limit | Motor locked  | Stop driving the motor and enter the lock state | Mechanical rotation error |
| Overcurrent Protection       | Short circuit | Stop driving the motor and enter the lock state | Circuit connection        |

#### 8.4.7.1 Acceleration Current Limit

The acceleration current limit limits the voltage applied to the motor to prevent the current from exceeding the programmed threshold. The acceleration current limit threshold is configured by writing the SWiLimitThr[3:0] bits to select  $I_{\text{LIMIT}}$ . The acceleration current limit does not use a direct measurement of current. It uses the programmed motor phase resistance,  $R_{\text{PH\_CT}}$ , and programmed BEMF constant,  $K_t$ , to limit the voltage applied to the motor,  $U$ , as shown in [Figure 32](#) and [Equation 8](#).

When the acceleration current limit is active, it does not stop the motor from spinning nor does it trigger a fault. The functionality of the acceleration current limit is only available in closed-loop control.

**Figure 32. Acceleration Current Limit**

$$U_{LIMIT} = I_{LIMIT} \times R_{PH\_CT} + \text{Speed} \times Kt \quad (8)$$

### 8.4.8 Lock Detect and Fault Handling

The DRV10983-Q1 device provides several options for determining if the motor becomes locked as a result of some external torque. Five lock-detect schemes work together to ensure the lock condition is detected quickly and reliably. Figure 33 shows the logic which integrates the various lock-detect schemes. When a lock condition is detected, the DRV10983-Q1 device takes action to prevent continuously driving the motor in order to prevent damage to the system or the motor.

In addition to detecting if there is a locked motor condition, the DRV10983-Q1 device also identifies and takes action if there is no motor connected to the system.

Each of the five lock-detect schemes and the no-motor detection can be disabled by respective register bits LockEn[5:0].

When a lock condition is detected, the FaultReg register provides an indication of which of the six different conditions was detected on Lock5 to Lock0. These bits are reset when the motor restarts. The bits in the FaultReg register are set even if the lock detect scheme is disabled.

The DRV10983-Q1 device reacts to either locked-rotor or no-motor-connected conditions by putting the output drivers into a high-impedance state. To prevent the energy in the motor from pumping the supply voltage, the DRV10983-Q1 device incorporates an anti-voltage-surge (AVS) process whenever the output stages transition into the high-impedance state. The AVS function is described in [Anti Voltage Suppression Function](#). After entering the high-impedance state as a result of a fault condition, the system tries to restart after  $t_{LOCK\_OFF}$ .

**Figure 33. Lock Detect and Fault Diagnose**

#### 8.4.8.1 Lock0: Lock-Detection Current Limit Triggered

The lock-detection current-limit function provides a configurable threshold for limiting the current to prevent damage to the system. This is often tripped in the event of a sudden locked-rotor condition. The DRV10983-Q1 device continuously monitors the current in the low-side drivers as shown in [Figure 34](#). If the current goes higher than the threshold configured by the HWiLimitThr[2:0] bits, then the DRV10983-Q1 device stops driving the motor by placing the output phases into a high-impedance state. The Lock0 bit is set and a lock condition is reported. It retries after  $t_{LOCK\_OFF}$ .

Set the lock-detection current limit to a higher value than the acceleration current limit.

Figure 34. Lock-Detection Current Limit

#### 8.4.8.2 Lock1: Abnormal Speed

If the motor is operating normally, the motor BEMF should always be less than the output amplitude. The DRV10983-Q1 device uses two methods of monitoring the BEMF in the system. The U phase current is monitored to maintain an estimate of BEMF based on the setting for Rm[6:0] {RmShift[2:0],RmValue[3:0]}. In addition, the BEMF is estimated based on the operation speed of the motor and the setting for Kt[6:0] {KtShift[2:0],KtValue[3:0]}. [Figure 35](#) shows the method for using this information to detect a lock condition. If the motor BEMF is much higher than the output amplitude for a certain period of time,  $t_{LCK\_ETR}$ , it means the estimated speed is wrong, and the motor has gotten out of phase.

Figure 35. Lock Detection 1

#### 8.4.8.3 Lock2: Abnormal Kt

For any given motor, the integrated value of BEMF during half of an electrical cycle is constant. The value is determined by the BEMF constant ( $K_{t_{PH}}$ ) (see [Figure 36](#)). The BEMF constant is the same regardless of whether the motor is running fast or slow. This constant value is continuously monitored by calculation and used as a criterion to determine the motor lock condition, and is referred to as Ktc.

Based on the  $K_{t_{PH}}$  value programmed, create a range from Kt\_low to Kt\_high. If Ktc goes beyond the range for a certain period of time,  $t_{LCK\_ETR}$ , lock is detected. Kt\_low and Kt\_high are determined by KtLckThr[1:0] (see [Figure 37](#)).

**Figure 36. BEMF Integration**

**Figure 37. Abnormal-Kt Lock Detect**

#### 8.4.8.4 Lock3 (Fault3): No-Motor Fault

The phase U current is checked after transitioning from open loop to closed loop. If phase U current is not greater than 140 mA then the motor is not connected as shown in [Figure 38](#). This condition is treated and reported as a fault.

**Figure 38. No Motor Error**

#### 8.4.8.5 Lock4: Open-Loop Motor-Stuck Lock

Lock4 is used to detect locked-motor conditions while the motor start sequence is in open loop.

For a successful startup, motor speed should be equal to the open-to-closed-loop handoff threshold when the motor is transitioning into closed loop. However, if the motor is locked, the motor speed is not able to match the open-loop drive rate.

If the motor BEMF is not detected for one electrical cycle after the open-loop drive rate exceeds the threshold, then the open loop was unsuccessful as a result of a locked-rotor condition.

#### 8.4.8.6 Lock5: Closed Loop Motor Stuck Lock

If the motor suddenly becomes locked, motor speed and Ktc are not able to be refreshed because the BEMF zero cross of the motor may not appear after the lock. In this condition, lock can also be detected by the following scheme: if the current commutation period is 2× longer than the previous period.

## 8.4.9 Anti Voltage Suppression Function

When a motor is driven, energy is transferred from the power supply into the motor. Some of this energy is stored in the form of inductive energy or as mechanical energy. The DRV10983-Q1 device includes circuits to prevent this energy from being returned to the power supply, which could result in pumping up the  $V_{CC}$  voltage. This function is referred to as the AVS and acts to protect the DRV10983-Q1 device as well as other circuits that share the same  $V_{CC}$  connection. Two forms of AVS protection are used to prevent both the mechanical energy and the inductive energy from being returned to the supply. Each of these modes can be independently disabled through the register configuration bits AVSMEn and AVSIndEn.

### 8.4.9.1 Mechanical AVS Function

If the speed command suddenly drops such that the BEMF voltage generated by the motor is greater than the voltage that is applied to the motor, then the mechanical energy of the motor is returned to the power supply and the  $V_{CC}$  voltage surges. The mechanical AVS function works to prevent this from happening. The DRV10983-Q1 device buffers the speed command value and limits the resulting output voltage,  $U_{MIN}$ , so that it is not less than the BEMF voltage of the motor. The BEMF voltage in the mechanical AVS function is determined using the programmed value for the motor  $K_t$  ( $K_t[6:0]$ ) along with the speed. Figure 39 shows the criteria used by the mechanical AVS function.

Figure 39. Mechanical AVS

The mechanical AVS function can operate in one of two modes, which can be configured by the register bit AVSMMd:

AVSMMd = 0 – AVS mode is always active to prevent the applied voltage from being less than the BEMF voltage.

AVSMMd = 1 – AVS mode becomes active when  $V_{CC}$  reaches 24 V. The motor acts as a generator and returns energy into the power supply until  $V_{CC}$  reaches 24 V. This mode can be used to enable faster deceleration of the motor in applications where returning energy to the power supply is allowed.

### 8.4.9.2 Inductive AVS Function

When the DRV10983-Q1 device transitions from driving the motor into a high-impedance state, the inductive current in the motor windings continues to flow and the energy returns to the power supply through the intrinsic body diodes in the FET output stage (see Figure 40).

Figure 40. Inductive-Mode Voltage Surge

To prevent the inductive energy from being returned to the power supply, the DRV10983-Q1 system transitions from driving to a high-impedance state by first turning OFF the active high-side drivers, and turning ON all low-side drivers. The DRV10983-Q1 device monitors phase current after entering the BRAKE state and transitions into the high-impedance state when the amplitude of the phase current is less than  $BrkCurThrSel$  for a fixed period of time ( $BrkDoneThr[2:0]$ ) (see Figure 41).

**Figure 41. Inductive AVS**

In this example, current is applied to the motor through the high-side driver on phase U (S1) and returned through the low-side driver on phase W (S6). The high-side driver on phase U is turned off and after a period of time (to allow the inductive energy in the resulting LR circuit to decay) the low-side driver on phase W is turned off. If `BrkDoneThr[2:0] = 000`, no brake will be applied and the device will not protect from inductive energy even with the inductive AVS feature enabled.

#### 8.4.10 PWM Output

The DRV10983-Q1 device has 32 options for PWM dead time. These options can be used to configure the time between one of the bridge FETs turning off and the complementary FET turning on. `Deadtime[4:0]` can be used to configure dead times between 40 and 1280 ns. Take care that the dead time is long enough to prevent the bridge FETs from shooting through.

The DRV10983-Q1 device offers two options for PWM switching frequency. When the configuration bit `PWMFreq` is set to 0, the output PWM frequency is 25 kHz, and when `PWMFreq` is set to 1, the output PWM frequency is 50 kHz.

#### 8.4.11 FG Customized Configuration

The DRV10983-Q1 device provides information about the motor speed through the *frequency generate* (FG) pin. FG also provides information about the driving state of the DRV10983-Q1 device.

##### 8.4.11.1 FG Output Frequency

The FG output frequency can be configured by `FGcycle[3:0]`. The default FG toggles once every electrical cycle (`FGcycle = 0000`). Many applications configure the FG output so that it provides two pulses for every mechanical rotation of the motor. The configuration bits provided in the DRV10983-Q1 device can accomplish this for 2-pole, 4-pole, 6-pole, and 8-pole motors up to 32-pole motors. This is illustrated in [Figure 42](#) for 2, 4, 6, and 8-pole motors.

[Figure 42](#) shows the DRV10983-Q1 device has been configured to provide FG pulses once every electrical cycle (4 poles), twice every three electrical cycles (6 poles), once every two electrical cycles (8 poles), and once every three electrical cycles (12 poles).

Note that when it is set to two FG pulses every three electrical cycles, the FG output is not 50% duty cycle. Motor speed is able to be measured by monitoring the rising edge of the FG output.

**Figure 42. FG Frequency Divider**

#### **8.4.11.2 FG Open Loop and Lock Behavior**

Note that the FG output reflects the driving state of the motor. During normal closed-loop behavior, the driving state and the actual state of the motor are synchronized. During open-loop acceleration, however, this may not reflect the actual motor speed. During a locked-motor condition, the FG output is driven high.

The DRV10983-Q1 device provides three options for controlling the FG output during open loop, as shown in [Figure 43](#). The selection of these options is determined by the FGOLSel[1:0] setting.

- Option0: Open-loop, FG output based on driving frequency
- Option1: Open-loop, no FG output (keep high)
- Option2: FG output based on driving frequency at the first power-on startup, and no FG output (keep high) for any subsequent restarts

**Figure 43. FG Behavior During Open Loop**

### 8.4.12 Diagnostics and Visibility

The DRV10983-Q1 device offers extensive visibility into the motor system operation conditions stored in internal registers. This information can be monitored through the I<sup>2</sup>C interface. Information can be monitored relating to the device status, motor speed, supply voltage, speed command, motor phase-voltage amplitude, fault status, and others. The data is updated on the fly.

#### 8.4.12.1 Motor-Status Readback

The motor FaultReg register provides information on overtemperature (OverTemp), overcurrent (OverCurr), and locked rotor (Lock0–Lock5).

#### 8.4.12.2 Motor-Speed Readback

The motor operation speed is automatically updated in register MotorSpeed while the motor is spinning. The value is determined by the period for calculated BEMF zero crossings on phase U. The electrical speed of the motor is denoted as *Velocity (Hz)* and is calculated as shown in Equation 9.

$$\text{Velocity (Hz)} = \{\text{MotorSpeed}\} / 10 \quad (9)$$

As an example consider the following:

MotorSpeed = 0x01FF;

Velocity = 512 (0x01FF) / 10 = 51 Hz

For a 4-pole motor, this translates to:

$$51 \frac{\text{cycles}}{\text{second}} \times \frac{1}{2} \frac{\text{mechcycle}}{\text{cycle}} \times 60 \frac{\text{second}}{\text{minute}} = 1530 \text{ RPM}$$

### 8.4.12.3 Motor Electrical-Period Readback

The motor-operation electrical period is automatically updated in register MotorPeriod while the motor is spinning. The electrical period is measured as the time between calculated BEMF zero crossings for phase U. The electrical period of the motor is denoted as  $t_{ELE\_PERIOD}$  ( $\mu$ s) and is calculated as shown in Equation 10.

$$t_{ELE\_PERIOD} (\mu s) = \{\text{MotorPeriod}\} \times 10 \quad (10)$$

As an example consider the following:

MotorPeriod = 0x01FF;

$$t_{ELE\_PERIOD} = 512 (0x01FF) \times 10 = 5120 \mu s$$

The motor electrical period and motor speed satisfies the condition of Equation 11.

$$t_{ELE\_PERIOD} (s) \times \text{Velocity} (Hz) = 1 \quad (11)$$

### 8.4.12.4 BEMF Constant Read Back

For any given motor, the integrated value of BEMF during half of an electronic cycle is a constant, Ktc (see [Lock2: Abnormal Kt](#)).

The integration of the motor BEMF is processed periodically (updated every electrical cycle) while the motor is spinning. The result is stored in register MotorKt.

The relationship is shown in .

$$Ktc (V/Hz) = \{\text{MotorKt}\} / 2 / 1090 \quad (12)$$

### 8.4.12.5 Motor Estimated Position by IPD

After inductive sense is executed, the rotor position is detected within 60 electrical degrees of resolution. The position is stored in register IPDPosition.

The value stored in IPDPosition corresponds to one of the six motor positions plus the IPD advance angle as shown in Table 8. For more information about IPD, see [Initial Position Detect \(IPD\)](#).

**Table 8. IPD Position Read Back**

|                    |  |  |  |  |  |  |
|--------------------|-------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------|
| Rotor position (°) | 0                                                                                   | 60                                                                                  | 120                                                                                 | 180                                                                                  | 240                                                                                   | 300                                                                                   |
| Data1              | 0                                                                                   | 43                                                                                  | 85                                                                                  | 128                                                                                  | 171                                                                                   | 213                                                                                   |
| IPD advance angle  | 30                                                                                  | 60                                                                                  | 90                                                                                  | 120                                                                                  |                                                                                       |                                                                                       |
| Data2              | 22                                                                                  | 44                                                                                  | 63                                                                                  | 85                                                                                   |                                                                                       |                                                                                       |
| Register data      | (Data1 + Data2) mod (256)                                                           |                                                                                     |                                                                                     |                                                                                      |                                                                                       |                                                                                       |

### 8.4.12.6 Supply-Voltage Readback

The power supply is monitored periodically during motor operation. This information is available in register SupplyVoltage. The power supply voltage is recorded as shown in Equation 13.

$$V_{POWERSUPPLY} (V) = \text{Supply Voltage} \times 30 V / 256 \quad (13)$$

#### 8.4.12.7 Speed-Command Readback

The DRV10983-Q1 device converts the various types of speed command into a speed command value (SpeedCmd) as shown in Figure 44. By reading SpeedCmd, the user can observe PWM input duty (PWM digital mode), analog voltage (analog mode), or I<sup>2</sup>C data (I<sup>2</sup>C mode). This value is calculated as shown in Equation 14.

Equation 14 shows how the speed command as a percentage can be calculated and set in SpeedCmd.

$$\text{Duty}_{\text{SPEED}} (\%) = \text{SpeedCmd} \times 100 / 255$$

where

- Duty<sub>SPEED</sub> = Speed command as a percentage
  - SpeedCmd = Register value
- (14)

#### 8.4.12.8 Speed-Command Buffer Readback

If acceleration current limit and AVS are enabled, the PWM duty cycle output (read back at spdCmdBuffer) may not always match the input command (read back at SpeedCmd) shown in Figure 44. See [Anti Voltage Suppression Function](#) and [Current Limit](#).

By reading the value of spdCmdBuffer, the user can observe buffered speed command (output PWM duty cycle) to the motor.

Equation 15 shows how the buffered speed is calculated.

$$\text{Duty}_{\text{OUTPUT}} (\%) = \text{spdCmdBuffer} \times 100 / 255$$

where

- Duty<sub>OUTPUT</sub> = The maximum duty cycle of the output PWM, which represents the output amplitude in percentage.
  - spdCmdBuffer = Register value
- (15)

**Figure 44. SpeedCmd and spdCmdBuffer Registers**

#### 8.4.12.9 Fault Diagnostics

See [Lock Detect and Fault Handling](#).

## 8.5 Register Maps

### 8.5.1 I<sup>2</sup>C Serial Interface

The DRV10983-Q1 device provides an I<sup>2</sup>C slave interface with slave address 101 0010. TI recommends a pullup resistor of 4.7 kΩ to 3.3 V for I<sup>2</sup>C interface ports SCL and SDA. The protocol for the I<sup>2</sup>C interface is given in Figure 45.

#### I2C Write

**Figure 45. I<sup>2</sup>C Protocol**

Seven read/write registers (0x30:0x36) are used to set motor speed and control device registers and EEPROM. Device operation status can be read back through nine read-only registers (0x00:0x08). Another seven EEPROM registers (0x90:0x96) can be accessed to program motor parameters and optimize the spin-up profile for the application.

### 8.5.2 Register Map

| REGISTER NAME                                 | ADDR. | D15                  | D14             | D13    | D12     | D11      | D10                | D9                   | D8               |
|-----------------------------------------------|-------|----------------------|-----------------|--------|---------|----------|--------------------|----------------------|------------------|

## 9 Application and Implementation

### NOTE

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

### 9.1 Application Information

The DRV10983-Q1 device is used in sensorless 3-phase BLDC motor control. The driver provides a high-performance, high-reliability, flexible, and simple solution for appliance fan, pump, and HVAC applications. The following design shows a common application of the DRV10983-Q1 device.

### 9.2 Typical Application

**Figure 71. Typical Application Schematic**

#### 9.2.1 Design Requirements

Table 36 provides design input parameters and motor parameters for system design.

## Typical Application (continued)

**Table 36. Recommended Application Range**

|                             |                                                  | MIN   | TYP | MAX  | UNIT     |
|-----------------------------|--------------------------------------------------|-------|-----|------|----------|
| Motor voltage               |                                                  | 6.2   | 12  | 28   | V        |

### 9.2.2 Detailed Design Procedure

1. See the [Design Requirements](#) section and make sure your system meets the recommended application range.
2. See the [DRV10983-Q1 Tuning Guide](#) and measure the motor parameters.
3. See the [DRV10983-Q1 Tuning Guide](#). Configure the parameters using the DRV10983-Q1 GUI, and optimize the motor operation. The *Tuning Guide* takes the user through all the configurations step by step, including: start-up operation, closed-loop operation, current control, initial positioning, lock detection, and anti-voltage surge.
4. Build your hardware based on [Layout Guidelines](#).
5. Connect the device into a system and validate your system solution.

## 9.2.3 Application Curves

## 10 Power Supply Recommendations

The DRV10983-Q1 device is designed to operate from an input voltage supply,  $V_{CC}$ , in a range between 8 V and 28 V. The user must place a 10- $\mu$ F ceramic capacitor rated for  $V_{CC}$  as close as possible to the  $V_{CC}$  and GND pins.

If the power supply ripple is more than 200 mV, in addition to the local decoupling capacitors, a bulk capacitance is required and must be sized according to the application requirements. If the bulk capacitance is implemented in the application, the user can reduce the value of the local ceramic capacitor to 1  $\mu$ F.

## 11 Layout

### 11.1 Layout Guidelines

- Place the  $V_{CC}$ , GND, U, V, and W pins with thick traces because high current passes through these traces.
- Place the 10- $\mu$ F capacitor between  $V_{CC}$  and GND, and as close to the  $V_{CC}$  and GND pins as possible.
- Place the capacitor between CPP and CPN, and as close to the CPP and CPN pins as possible.
- Connect the GND, PGND, and SWGND under the thermal pad.
- Keep the thermal pad connection as large as possible, on both the bottom side and top sides. It should be one piece of copper without any gaps.
- If EEPROM is programmed, it is okay to leave SCL and SDA floating.

### 11.2 Layout Example

**Figure 74. Layout Diagram**

## 12 Device and Documentation Support

### 12.1 Trademarks

PowerPAD, E2E are trademarks of Texas Instruments.  
All other trademarks are the property of their respective owners.

### 12.2 Electrostatic Discharge Caution

These devices have limited built-in ESD protection. The leads should be shorted together or the device placed in conductive foam during storage or handling to prevent electrostatic damage to the MOS gates.

### 12.3 Receiving Notification of Documentation Updates

To receive notification of documentation updates, navigate to the device product folder on ti.com. In the upper right corner, click on *Alert me* to register and receive a weekly digest of any product information that has changed. For change details, review the revision history included in any revised document.

### 12.4 Community Resources

[TI E2E™ support forums](#) are an engineer's go-to source for fast, verified answers and design help — straight from the experts. Search existing answers or ask your own question to get the quick design help you need.

Linked content is provided "AS IS" by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's [Terms of Use](#).

### 12.5 Glossary

[SLYZ022](#) — *TI Glossary*.

This glossary lists and explains terms, acronyms, and definitions.

## 13 Mechanical, Packaging, and Orderable Information

The following pages include mechanical, packaging, and orderable information. This information is the most-current data available for the designated devices. This data is subject to change without notice and without revision of this document. For browser-based versions of this data sheet, see the left-hand navigation pane.

<sup>(1)</sup> **Status:** For more details on status, see our [product life cycle](#).

<sup>(2)</sup> **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

<sup>(3)</sup> **RoHS values:** Yes, No, RoHS Exempt. See the [TI RoHS Statement](#) for additional information and value definition.

<sup>(4)</sup> **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

<sup>(5)</sup> **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

<sup>(6)</sup> **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.

**Important Information and Disclaimer:** The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

## PACKAGE OUTLINE

SMALL OUTLINE PACKAGE

NOTES:

PowerPAD is a trademark of Texas Instruments.

1. All linear dimensions are in millimeters. Any dimensions in parenthesis are for reference only. Dimensioning and tolerancing per ASME Y14.5M.
2. This drawing is subject to change without notice.
3. This dimension does not include mold flash, protrusions, or gate burrs. Mold flash, protrusions, or gate burrs shall not exceed 0.15 mm per side.
4. Reference JEDEC registration MO-153.
5. Features may differ or may not be present.

# EXAMPLE BOARD LAYOUT

PWP0024R

PowerPAD™ TSSOP - 1.2 mm max height

SMALL OUTLINE PACKAGE

4229639/B 12/2023

NOTES: (continued)

6. Publication IPC-7351 may have alternate designs.
7. Solder mask tolerances between and around signal pads can vary based on board fabrication site.
8. This package is designed to be soldered to a thermal pad on the board. For more information, see Texas Instruments literature numbers SLMA002 ([www.ti.com/lit/slma002](http://www.ti.com/lit/slma002)) and SLMA004 ([www.ti.com/lit/slma004](http://www.ti.com/lit/slma004)).
9. Size of metal pad may vary due to creepage requirement.
10. Vias are optional depending on application, refer to device data sheet. It is recommended that vias under paste be filled, plugged or tented.

# EXAMPLE STENCIL DESIGN

PWP0024R

PowerPAD™ TSSOP - 1.2 mm max height

SMALL OUTLINE PACKAGE

**SOLDER PASTE EXAMPLE**  
BASED ON 0.125 mm THICK STENCIL  
SCALE: 8X

| STENCIL THICKNESS | SOLDER STENCIL OPENING |
|-------------------|------------------------|
| 0.1               | 3.58 X 5.88            |
| 0.125             | 3.20 X 5.26 (SHOWN)    |
| 0.15              | 2.92 X 4.80            |
| 0.175             | 2.70 X 4.45            |

4229639/B 12/2023

NOTES: (continued)

11. Laser cutting apertures with trapezoidal walls and rounded corners may offer better paste release. IPC-7525 may have alternate design recommendations.
12. Board assembly site may have different recommendations for stencil design.

## IMPORTANT NOTICE AND DISCLAIMER

TI PROVIDES TECHNICAL AND RELIABILITY DATA (INCLUDING DATASHEETS), DESIGN RESOURCES (INCLUDING REFERENCE DESIGNS), APPLICATION OR OTHER DESIGN ADVICE, WEB TOOLS, SAFETY INFORMATION, AND OTHER RESOURCES "AS IS" AND WITH ALL FAULTS, AND DISCLAIMS ALL WARRANTIES, EXPRESS AND IMPLIED, INCLUDING WITHOUT LIMITATION ANY IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE OR NON-INFRINGEMENT OF THIRD PARTY INTELLECTUAL PROPERTY RIGHTS.

These resources are intended for skilled developers designing with TI products. You are solely responsible for (1) selecting the appropriate TI products for your application, (2) designing, validating and testing your application, and (3) ensuring your application meets applicable standards, and any other safety, security, regulatory or other requirements.

These resources are subject to change without notice. TI grants you permission to use these resources only for development of an application that uses the TI products described in the resource. Other reproduction and display of these resources is prohibited. No license is granted to any other TI intellectual property right or to any third party intellectual property right. TI disclaims responsibility for, and you fully indemnify TI and its representatives against any claims, damages, costs, losses, and liabilities arising out of your use of these resources.

TI's products are provided subject to [TI's Terms of Sale](#), [TI's General Quality Guidelines](#), or other applicable terms available either on [ti.com](https://www.ti.com) or provided in conjunction with such TI products. TI's provision of these resources does not expand or otherwise alter TI's applicable warranties or warranty disclaimers for TI products. Unless TI explicitly designates a product as custom or customer-specified, TI products are standard, catalog, general purpose devices.
