Trademarks	130
► C29x SYSTEM RESOURCES	131
Technical Reference Manual Overview	131
1 C29x Processor	133
1.1 CPU Architecture	134
1.1.1 C29x Related Collateral	135
1.2 Lock and Commit Registers	135
1.3 C29x CPU Registers	136
1.3.1 C29CPU Base Address Table	136
1.3.2 C29_RTINT_STACK Registers	137
1.3.3 C29_SECCALL_STACK Registers	151
1.3.4 C29_SECURE_REGS Registers	155
1.3.5 C29_DIAG_REGS Registers	172
1.3.6 C29_SELFTEST_REGS Registers	178
2 System Control and Interrupts	187
2.1 C29x System Control Introduction	188
2.2 System Control Functional Description	188
2.2.1 Device Identification	188
2.2.2 Device Configuration Registers	189
2.3 Resets	189
2.3.1 Reset Sources	189
2.3.2 External Reset (XRS)	191
2.3.3 Simulate External Reset	191
2.3.4 Power-On Reset (POR)	192
2.3.5 Debugger Reset (SYSRS)	192
2.3.6 Watchdog Reset (WDRS)	193
2.3.7 ESM NMI Watchdog Reset (NMIWDRS)	193
2.3.8 EtherCAT SubordinateDevice Controller (ESC) Module Reset Output	193
2.4 Interrupts	193
2.4.1 External Interrupts (XINT)	193
2.5 Safety Features	194
2.5.1 Write Protection on Registers	194
2.5.2 PIPE Vector Address Validity Check	194
2.5.3 NMIWDs	194
2.5.4 System Control Registers Parity Protection	194
2.5.5 ECC Enabled RAMs, Shared RAMs Protection	194
2.5.6 ECC Enabled Flash Memory	194
2.5.7 ERRORSTS Pin	195
2.6 Clocking	196
2.6.1 Clock Sources	197
2.6.2 Derived Clocks	199
2.6.3 Device Clock Domains	200
2.6.4 External Clock Output (XCLKOUT)	201

2.6.5 Clock Connectivity.....	201
2.6.6 Using an External Crystal or Resonator.....	203
2.6.7 PLL.....	204
2.6.8 Clock (OSCCLK) Failure Detection.....	206
2.7 Bus Architecture.....	208
2.7.1 Safe Interconnect.....	208
2.7.2 Peripheral Access Configuration using FRAMESEL.....	209
2.7.3 Bus Arbitration.....	210
2.8 32-Bit CPU Timers 0/1/2.....	211
2.9 Watchdog Timers.....	212
2.9.1 Servicing the Watchdog Timer.....	213
2.9.2 Minimum Window Check.....	213
2.9.3 Watchdog Reset or Watchdog Interrupt Mode.....	214
2.9.4 Watchdog Operation in Low-Power Modes.....	214
2.9.5 Emulation Considerations.....	214
2.10 Low-Power Modes.....	215
2.10.1 IDLE.....	215
2.10.2 STANDBY.....	215
2.11 Memory Subsystem (MEMSS).....	216
2.11.1 Introduction.....	216
2.11.2 Features.....	216
2.11.3 Configuration Bits.....	217
2.11.4 RAM.....	217
2.11.5 ROM.....	234
2.11.6 Arbitration.....	235
2.11.7 Test Modes.....	238
2.11.8 Emulation Mode.....	238
2.12 System Control Register Configuration Restrictions.....	239
2.13 Device Initialization Software Sequence	239
2.13.1 Boot Start-Up Flow.....	239
2.13.2 Application Start-Up Flow.....	239
2.14 Software.....	243
2.14.1 SYSCTL Registers to Driverlib Functions.....	243
2.14.2 MEMSS Registers to Driverlib Functions.....	257
2.14.3 CPU Registers to Driverlib Functions.....	264
2.14.4 CPUTIMER Registers to Driverlib Functions.....	266
2.14.5 XINT Registers to Driverlib Functions.....	266
2.14.6 LPOST Registers to Driverlib Functions.....	267
2.14.7 SYSCTL Examples.....	267
2.14.8 TIMER Examples.....	268
2.14.9 WATCHDOG Examples.....	269
2.14.10 LPM Examples.....	269
2.15 SYSCTRL Registers.....	270
2.15.1 SYSCTRL Base Address Table.....	270
2.15.2 DEV_CFG_REGS Registers.....	272
2.15.3 MEMSS_L_CONFIG_REGS Registers.....	523
2.15.4 MEMSS_C_CONFIG_REGS Registers.....	555
2.15.5 MEMSS_M_CONFIG_REGS Registers.....	599
2.15.6 MEMSS_MISCI_REGS Registers.....	603
2.15.7 SYNCBRIDGEMPU_REGS Registers.....	610
2.15.8 CPU_SYS_REGS Registers.....	619
2.15.9 CPU_PER_CFG_REGS Registers.....	656
2.15.10 WD_REGS Registers.....	720
2.15.11 CPUTIMER_REGS Registers.....	727
2.15.12 XINT_REGS Registers.....	734
3 ROM Code and Peripheral Booting.....	743
3.1 Introduction.....	744
3.1.1 ROM Related Collateral.....	744
3.2 Device Boot Sequence.....	745
3.3 Device Boot Modes.....	746
3.3.1 Default Boot Modes.....	746

3.3.2 Custom Boot Modes.....	747
3.4 Device Boot Configurations.....	748
3.4.1 Configuring Boot Mode Pins.....	749
3.4.2 Configuring Boot Mode Table Options.....	751
3.4.3 Boot Mode Example Use Cases.....	752
3.5 Device Boot Flow Diagrams.....	754
3.5.1 Device Boot Flow.....	754
3.5.2 CPU1 Boot Flow.....	756
3.5.3 Emulation Boot Flow.....	757
3.5.4 Standalone Boot Flow.....	757
3.6 Device Reset and Exception Handling.....	760
3.6.1 Reset Causes and Handling.....	760
3.6.2 Exceptions and Interrupts Handling.....	760
3.7 Boot ROM Description.....	764
3.7.1 Boot ROM Configuration Registers.....	764
3.7.2 Entry Points.....	764
3.7.3 Wait Points.....	765
3.7.4 Memory Maps.....	765
3.7.5 BootROM SSU APRs.....	766
3.7.6 LINK1 RAMOPEN.....	767
3.7.7 ROM Structure and Status Information.....	767
3.7.8 Boot Modes and Loaders.....	767
3.7.9 GPIO Assignments.....	776
3.7.10 HSM and C29x ROM Task Ownership and Interactions.....	778
3.7.11 Boot Status Information.....	780
3.7.12 BootROM Timing.....	783
3.8 Software.....	783
3.8.1 BOOT Examples.....	783
4 Lockstep Compare Module (LCM).....	784
4.1 Introduction.....	785
4.1.1 Features.....	785
4.1.2 Block Diagram.....	785
4.1.3 Lockstep Compare Modules.....	786
4.2 Enabling LCM Comparators.....	786
4.3 LCM Redundant Module Configuration.....	786
4.4 LCM Error Handling.....	787
4.5 Register Parity Error Protection.....	787
4.6 Functional Logic.....	788
4.6.1 Comparator Logic.....	788
4.6.2 Self-Test Logic.....	788
4.6.3 Error Injection Tests.....	791
4.7 Software.....	792
4.7.1 LCM Registers to Driverlib Functions.....	792
4.8 LCM Registers.....	792
4.8.1 LCM Base Address Table.....	792
4.8.2 LCM_REGS Registers.....	793
5 Peripheral Interrupt Priority and Expansion (PIPE) and C29 CPU Interrupts.....	807
5.1 Introduction.....	808
5.1.1 Features.....	808
5.1.2 PIPE Related Collateral.....	808
5.2 Interrupts.....	808
5.2.1 CPU Interrupts Architecture Block Diagram.....	809
5.2.2 RESET, NMI, RTINT, and INT.....	810
5.2.3 Conditions Blocking Interrupts.....	813
5.3 Interrupt Controller Architecture.....	815
5.3.1 Dynamic Priority Arbitration Block.....	815
5.3.2 Post Processing Block.....	815
5.3.3 Memory-Mapped Registers.....	815
5.4 Interrupt Propagation.....	816
5.5 Configuring Interrupts.....	817
5.5.1 Enabling and Disabling Interrupts.....	817

5.5.2 Prioritization.....	819
5.5.3 Interrupt Nesting.....	826
5.5.4 Stack Protection.....	829
5.5.5 Context.....	831
5.5.6 Live Firmware Update (LFU) Vector Mapping.....	831
5.6 Safety and Security.....	832
5.6.1 Access Control.....	832
5.6.2 PIPE Errors.....	832
5.6.3 Register Data Integrity and Safety.....	833
5.6.4 Self-Test and Diagnostics.....	834
5.7 Software.....	836
5.7.1 PIPE Registers to Driverlib Functions.....	836
5.7.2 INTERRUPT Examples.....	838
5.8 PIPE Registers.....	841
5.8.1 PIPE Base Address Table.....	841
5.8.2 PIPE_REGS Registers.....	842
6 Error Aggregator.....	892
6.1 Introduction.....	893
6.2 Error Aggregator Modules.....	893
6.3 Error Propagation Path from Source to CPU.....	894
6.4 Error Aggregator Interface.....	894
6.4.1 Functional Description.....	896
6.5 Error Condition Handling User Guide.....	896
6.6 Error Type Information.....	897
6.7 Error Sources Information.....	901
6.8 Software.....	904
6.8.1 ERROR_AGGREGATOR Registers to Driverlib Functions.....	904
6.9 ERRORAGGREGATOR Registers.....	911
6.9.1 ERRORAGGREGATOR Base Address Table.....	911
6.9.2 HSM_ERROR_AGGREGATOR_CONFIG_REGS Registers.....	912
6.9.3 ERROR_AGGREGATOR_CONFIG_REGS Registers.....	920
7 Error Signaling Module (ESM_C29).....	1096
7.1 Introduction.....	1097
7.1.1 Features.....	1097
7.1.2 ESM Related Collateral.....	1097
7.2 ESM Subsystem.....	1098
7.2.1 System ESM	1099
7.2.2 Safety Aggregator.....	1100
7.2.3 ESM Subsystem Integration View.....	1101
7.3 ESM Functional Description.....	1104
7.3.1 Error Event Inputs.....	1106
7.3.2 Error Interrupt Outputs	1119
7.3.3 Error Pin Output (ERR_O/ERRORSTS).....	1121
7.3.4 Reset Type Information for ESM Registers.....	1126
7.3.5 Clock Stop	1127
7.3.6 Commit/Lock for MMRs.....	1127
7.3.7 Safety Protection for MMRs	1127
7.3.8 Register Configuration Tieoffs.....	1128
7.4 ESM Configuration Guide.....	1128
7.5 Interrupt Condition Control and Handling.....	1130
7.5.1 ESM Low-Priority Error Interrupt.....	1130
7.5.2 ESM High-Priority Error Interrupt.....	1131
7.5.3 Critical-Priority Error Interrupt.....	1132
7.5.4 High-Priority Watchdog Interrupt.....	1132
7.5.5 Safety Aggregator Interrupt Control and Handling.....	1132
7.6 Software.....	1133
7.6.1 ESM_CPU Registers to Driverlib Functions.....	1133
7.6.2 ESM_SYS Registers to Driverlib Functions.....	1135
7.6.3 ESM_SAFETY_AGGREGATOR Registers to Driverlib Functions.....	1137
7.6.4 ESM Examples.....	1138
7.7 ESM Registers.....	1139

7.7.1 ESM Base Address Table.....	1139
7.7.2 ESM_CPU_REGS Registers.....	1140
7.7.3 ESM_SYSTEM_REGS Registers.....	1169
7.7.4 ESM_SAFETYAGG_REGS Registers.....	1206
7.7.5 EDC_REGS Registers.....	1219
8 Flash Module.....	1226
8.1 Introduction to Flash Memory.....	1227
8.1.1 FLASH Related Collateral.....	1227
8.1.2 Features.....	1227
8.1.3 Flash Tools.....	1228
8.1.4 Block Diagram.....	1228
8.2 Flash Subsystem Overview.....	1229
8.3 Flash Banks and Pumps.....	1229
8.4 Flash Read Interfaces.....	1230
8.4.1 Bank Modes and Swapping.....	1231
8.4.2 Flash Wait States.....	1231
8.4.3 Buffer and Cache Mechanisms.....	1232
8.4.4 Flash Read Arbitration.....	1236
8.4.5 Error Correction Code (ECC) Protection.....	1236
8.4.6 Procedure to Change Flash Read Interface Registers.....	1237
8.5 Flash Erase and Program.....	1237
8.5.1 Flash Semaphore and Update Protection.....	1238
8.5.2 Erase.....	1238
8.5.3 Program.....	1238
8.6 Read-While-Write Constraints.....	1239
8.7 Migrating an Application from RAM to Flash.....	1240
8.8 Flash Registers.....	1240
8.8.1 FLASH Base Address Table.....	1240
8.8.2 FLASH_CMD_REGS_FLC1 Registers.....	1241
8.8.3 FLASH_CMD_REGS_FLC2 Registers.....	1247
8.8.4 FRI_CTRL_REGS Registers.....	1253
9 Safety and Security Unit (SSU).....	1278
9.1 Introduction.....	1279
9.1.1 SSU Related Collateral.....	1279
9.1.2 Block Diagram.....	1280
9.1.3 System SSU Configuration Example.....	1281
9.2 Access Protection Ranges.....	1282
9.2.1 Access Protection Inheritance.....	1282
9.3 LINKs.....	1283
9.4 STACKs.....	1286
9.5 ZONEs.....	1286
9.6 SSU-CPU Interface.....	1288
9.6.1 SSU Operation in Lockstep Mode.....	1288
9.7 SSU Operation Modes.....	1289
9.8 Security Configuration and Flash Management.....	1290
9.8.1 BANKMGMT Sectors.....	1290
9.8.2 SECCFG Sectors.....	1291
9.8.3 SECCFG Sector Address Mapping.....	1292
9.8.4 SECCFG Sector Memory Map.....	1293
9.8.5 SECCFG CRC.....	1301
9.9 Flash Write/Erase Access Control.....	1302
9.9.1 Permanent Flash Lock (Write/Erase Protection).....	1303
9.9.2 Updating Flash MAIN Sectors.....	1304
9.9.3 Firmware-Over-The-Air Updates (FOTA).....	1305
9.9.4 Updating Flash SECCFG Sectors.....	1306
9.9.5 Reading Flash SECCFG Sectors.....	1306
9.10 RAMOPEN Feature.....	1307
9.11 Booting of CPU2 and CPU3.....	1307
9.12 Debug Authorization.....	1309
9.12.1 Global CPU Debug Enable.....	1309
9.12.2 ZONE Debug.....	1309

9.12.3 Authentication for Debug Access.....	1309
9.13 Hardcoded Protections.....	1311
9.14 SSU Register Access Permissions.....	1312
9.14.1 Permissions for SSU General Control Registers.....	1312
9.14.2 Permissions for SSU CPU1 Configuration Registers.....	1314
9.14.3 Permissions for SSU CPU2+ Configuration Registers.....	1315
9.14.4 Permissions for CPU1 Access Protection Registers.....	1316
9.14.5 Permissions for CPU2+ Access Protection Registers.....	1316
9.15 SSU Fault Signals.....	1316
9.16 Software.....	1318
9.16.1 SSU Registers to Driverlib Functions.....	1318
9.17 SSU Registers.....	1323
9.17.1 SSU Base Address Table.....	1323
9.17.2 SSU_GEN_REGS Registers.....	1324
9.17.3 SSU_CPU1_CFG_REGS Registers.....	1406
9.17.4 SSU_CPU2_CFG_REGS Registers.....	1435
9.17.5 SSU_CPU3_CFG_REGS Registers.....	1469
9.17.6 SSU_CPU1_AP_REGS Registers.....	1503
9.17.7 SSU_CPU2_AP_REGS Registers.....	1513
9.17.8 SSU_CPU3_AP_REGS Registers.....	1523
9.18 C29DEBUGSS Registers.....	1532
9.18.1 C29DEBUGSS Base Address Table.....	1532
9.18.2 SECAP_HANDLER_REGS Registers.....	1533
10 Configurable Logic Block (CLB).....	1563
10.1 Introduction.....	1564
10.1.1 CLB Related Collateral.....	1564
10.2 Description.....	1564
10.2.1 CLB Clock.....	1566
10.3 CLB Input/Output Connection.....	1568
10.3.1 Overview.....	1568
10.3.2 CLB Input Selection.....	1568
10.3.3 CLB Output Selection.....	1582
10.3.4 CLB Output Signal Multiplexer.....	1584
10.4 CLB Tile.....	1587
10.4.1 Static Switch Block.....	1588
10.4.2 Counter Block.....	1590
10.4.3 FSM Block.....	1594
10.4.4 LUT4 Block.....	1596
10.4.5 Output LUT Block.....	1596
10.4.6 Asynchronous Output Conditioning (AOC) Block.....	1597
10.4.7 High Level Controller (HLC).....	1600
10.5 CPU Interface.....	1605
10.5.1 Register Description.....	1605
10.5.2 Non-Memory Mapped Registers.....	1606
10.6 RTDMA Access	1606
10.7 CLB Data Export Through SPI RX Buffer.....	1607
10.8 CLB Pipeline Mode.....	1608
10.9 Software.....	1609
10.9.1 CLB Registers to Driverlib Functions.....	1609
10.9.2 CLB Examples.....	1612
10.10 CLB Registers.....	1613
10.10.1 CLB Base Address Table.....	1613
10.10.2 CLB_LOGIC_CONFIG_REGS Registers.....	1615
10.10.3 CLB_LOGIC_CONTROL_REGS Registers.....	1667
10.10.4 CLB_DATA_EXCHANGE_REGS Registers.....	1700
11 Dual-Clock Comparator (DCC).....	1703
11.1 Introduction.....	1704
11.1.1 Features.....	1704
11.1.2 Block Diagram.....	1704
11.2 Module Operation.....	1705
11.2.1 Configuring DCC Counters.....	1706

11.2.2 Single-Shot Measurement Mode.....	1707
11.2.3 Continuous Monitoring Mode.....	1708
11.2.4 Error Conditions.....	1709
11.3 Interrupts.....	1711
11.4 Software.....	1712
11.4.1 DCC Registers to Driverlib Functions.....	1712
11.4.2 DCC Examples.....	1712
11.5 DCC Registers.....	1714
11.5.1 DCC Base Address Table.....	1714
11.5.2 DCC_REGS Registers.....	1715
12 Real-Time Direct Memory Access (RTDMA).....	1727
12.1 Introduction.....	1728
12.1.1 Features.....	1728
12.1.2 RTDMA Related Collateral.....	1728
12.1.3 Block Diagram.....	1729
12.2 RTDMA Trigger Source Options.....	1729
12.3 RTDMA Bus.....	1734
12.4 Address Pointer and Transfer Control.....	1735
12.5 Pipeline Timing and Throughput.....	1741
12.6 Channel Priority.....	1744
12.6.1 Round-Robin Mode.....	1744
12.6.2 Software Configurable Priority of Channels.....	1745
12.7 Overrun Detection Feature.....	1745
12.8 Burst Mode.....	1746
12.9 Safety and Security.....	1746
12.9.1 Safety.....	1746
12.9.2 Security.....	1750
12.9.3 RTDMA Errors.....	1750
12.9.4 Self-Test and Diagnostics.....	1751
12.10 Software.....	1751
12.10.1 RTDMA Registers to Driverlib Functions.....	1751
12.10.2 RTDMA Examples.....	1754
12.11 RTDMA Registers.....	1759
12.11.1 RTDMA Base Address Table.....	1759
12.11.2 RTDMA_REGS Registers.....	1761
12.11.3 RTDMA_DIAG_REGS Registers.....	1772
12.11.4 RTDMA_SELFTEST_REGS Registers.....	1777
12.11.5 RTDMA_MPU_REGS Registers.....	1785
12.11.6 RTDMA_CH_REGS Registers.....	1796
13 External Memory Interface (EMIF).....	1830
13.1 Introduction.....	1831
13.1.1 Purpose of the Peripheral.....	1831
13.1.2 Features.....	1832
13.1.3 Functional Block Diagram.....	1833
13.1.4 Configuring Device Pins.....	1833
13.2 EMIF Module Architecture.....	1834
13.2.1 EMIF Clock Control.....	1834
13.2.2 EMIF Requests.....	1834
13.2.3 EMIF Signal Descriptions.....	1835
13.2.4 EMIF Signal Multiplexing Control.....	1836
13.2.5 SDRAM Controller and Interface.....	1836
13.2.6 Asynchronous Controller and Interface.....	1849
13.2.7 Data Bus Parking.....	1861
13.2.8 Reset and Initialization Considerations.....	1861
13.2.9 Interrupt Support.....	1861
13.2.10 RTDMA Event Support.....	1862
13.2.11 EMIF Signal Multiplexing.....	1862
13.2.12 Memory Map.....	1862
13.2.13 Priority and Arbitration.....	1863
13.2.14 System Considerations.....	1863
13.2.15 Power Management.....	1864

13.2.16 Emulation Considerations.....	1864
13.3 EMIF Subsystem (EMIFSS).....	1864
13.3.1 Burst Support.....	1865
13.3.2 EMIFSS Performance Improvement.....	1865
13.3.3 Buffer Module.....	1867
13.3.4 Emulation Mode.....	1869
13.4 Example Configuration.....	1869
13.4.1 Hardware Interface.....	1869
13.4.2 Software Configuration.....	1870
13.5 Software.....	1879
13.5.1 EMIF Registers to Driverlib Functions.....	1879
13.5.2 EMIF Examples.....	1880
13.6 EMIF Registers.....	1881
13.6.1 EMIF Base Address Table.....	1881
13.6.2 EMIF_REGS Registers.....	1882
14 General-Purpose Input/Output (GPIO).....	1902
14.1 Introduction.....	1903
14.1.1 GPIO Related Collateral.....	1904
14.2 Configuration Overview.....	1904
14.3 Digital Inputs on ADC Pins (AIOs).....	1905
14.4 Digital Inputs and Outputs on ADC Pins (AGPIOs).....	1906
14.5 Digital General-Purpose I/O Control.....	1907
14.6 Input Qualification.....	1908
14.6.1 No Synchronization (Asynchronous Input).....	1908
14.6.2 Synchronization to SYSCLKOUT Only.....	1908
14.6.3 Qualification Using a Sampling Window.....	1909
14.7 PMBUS and I2C Signals.....	1912
14.8 GPIO and Peripheral Muxing.....	1913
14.8.1 GPIO Muxing.....	1913
14.8.2 Peripheral Muxing.....	1923
14.9 Internal Pullup Configuration Requirements.....	1925
14.10 Open-Drain Configuration Requirements.....	1925
14.11 Software.....	1925
14.11.1 GPIO Registers to Driverlib Functions.....	1925
14.11.2 GPIO Examples.....	1932
14.11.3 LED Examples.....	1933
14.12 GPIO Registers.....	1936
14.12.1 GPIO Base Address Table.....	1936
14.12.2 GPIO_CTRL_REGS Registers.....	1937
14.12.3 GPIO_DATA_REGS Registers.....	2150
14.12.4 GPIO_DATA_READ_REGS Registers.....	2218
15 Interprocessor Communication (IPC).....	2226
15.1 Introduction.....	2227
15.2 IPC Flags and Interrupts.....	2228
15.3 IPC Command Registers.....	2229
15.4 Free-Running Counter.....	2229
15.5 IPC Communication Protocol.....	2229
15.6 Software.....	2230
15.6.1 IPC Registers to Driverlib Functions.....	2230
15.6.2 IPC Examples.....	2234
15.7 IPC Registers.....	2237
15.7.1 IPC Base Address Table.....	2237
15.7.2 IPC_COUNTER_REGS Registers.....	2238
15.7.3 CPU1_IPC_SEND_REGS Registers.....	2241
15.7.4 CPU2_IPC_SEND_REGS Registers.....	2278
15.7.5 CPU3_IPC_SEND_REGS Registers.....	2315
15.7.6 CPU1_IPC_RCV_REGS Registers.....	2352
15.7.7 CPU2_IPC_RCV_REGS Registers.....	2374
15.7.8 CPU3_IPC_RCV_REGS Registers.....	2396
16 Embedded Real-time Analysis and Diagnostic (ERAD).....	2418
16.1 Introduction.....	2419

16.2 Enhanced Bus Comparator Unit.....	2420
16.2.1 Enhanced Bus Comparator Unit Operations.....	2420
16.2.2 Stack Qualification.....	2421
16.2.3 Event Masking and Exporting.....	2421
16.3 System Event Counter Unit.....	2422
16.3.1 System Event Counter Modes.....	2422
16.3.2 Reset on Event.....	2429
16.3.3 Operation Conditions.....	2429
16.4 Program Counter Trace.....	2430
16.4.1 Built-in CCS™ Trace.....	2431
16.4.2 Functional Block Diagram.....	2432
16.4.3 Trace Qualification Modes.....	2433
16.4.4 Trace Memory.....	2434
16.4.5 PC Trace Software Operation.....	2435
16.4.6 Trace Operation in Debug Mode.....	2435
16.5 ERAD Ownership, Initialization, and Reset.....	2435
16.5.1 Feature Level Ownership.....	2436
16.5.2 Feature Access Security Mechanism.....	2436
16.5.3 PC Trace Access Security Mechanism.....	2438
16.6 ERAD Programming Sequence.....	2439
16.6.1 Hardware Breakpoint and Hardware Watch Point Programming Sequence.....	2439
16.6.2 Timer and Counter Programming Sequence.....	2440
16.7 Software.....	2441
16.7.1 ERAD Registers to Driverlib Functions.....	2441
16.8 ERAD Registers.....	2443
16.8.1 ERAD Base Address Table.....	2443
16.8.2 ERAD_REGS Registers.....	2444
17 Data Logger and Trace (DLT).....	2489
17.1 Introduction.....	2490
17.1.1 Features.....	2490
17.1.2 DLT Related Collateral.....	2490
17.1.3 Interfaces.....	2490
17.2 Functional Overview.....	2492
17.2.1 DLT Configuration.....	2492
17.2.2 Time-stamping.....	2495
17.2.3 FIFO Construction.....	2496
17.3 Software.....	2498
17.3.1 DLT Registers to Driverlib Functions.....	2498
17.3.2 DLT Examples.....	2499
17.4 DLT Registers.....	2500
17.4.1 DLT Base Address Table.....	2500
17.4.2 DLT_CORE_REGS Registers.....	2501
17.4.3 DLT_FIFO_REGS Registers.....	2523
18 Waveform Analyzer Diagnostic (WADI).....	2527
18.1 WADI Overview.....	2528
18.1.1 Features.....	2528
18.1.2 WADI Related Collateral.....	2528
18.1.3 Block Diagram.....	2529
18.1.4 Description.....	2529
18.2 Signal and Trigger Input Configuration.....	2530
18.2.1 SIG1 and SIG2 Configuration.....	2530
18.2.2 Trigger 1 and Trigger 2.....	2531
18.3 WADI Block.....	2533
18.3.1 Overview.....	2533
18.3.2 Counters.....	2533
18.3.3 Pulse Width.....	2534
18.3.4 Edge Count.....	2535
18.3.5 Signal1 to Signal2 Comparison.....	2537
18.3.6 Dead Band and Phase.....	2539
18.3.7 Simultaneous Measurement.....	2540
18.4 Safe State Sequencer (SSS).....	2541

18.4.1 SSS Configuration.....	2541
18.5 Lock and Commit Registers.....	2547
18.6 Interrupt and Error Handling.....	2547
18.7 RTDMA Interfaces.....	2548
18.7.1 RTDMA Trigger.....	2549
18.8 Software.....	2549
18.8.1 WADI Registers to Driverlib Functions.....	2549
18.8.2 WADI Examples.....	2555
18.9 WADI Registers.....	2556
18.9.1 WADI Base Address Table.....	2556
18.9.2 WADI_CONFIG_REGS Registers.....	2557
18.9.3 WADI_OPER_SSS_REGS Registers.....	2592
19 Crossbar (X-BAR).....	2683
19.1 X-BAR Related Collateral.....	2684
19.2 Input X-BAR, ICL XBAR, MINDB XBAR.....	2684
19.2.1 ICL and MINDB X-BAR.....	2690
19.3 ePWM , CLB, GPIO Output X-BAR.....	2695
19.3.1 ePWM X-BAR.....	2695
19.3.2 CLB X-BAR.....	2706
19.3.3 GPIO Output X-BAR.....	2715
19.3.4 X-BAR Flags.....	2724
19.4 Software.....	2726
19.4.1 INPUT_XBAR Registers to Driverlib Functions.....	2726
19.4.2 EPWM_XBAR Registers to Driverlib Functions.....	2726
19.4.3 CLB_XBAR Registers to Driverlib Functions.....	2726
19.4.4 OUTPUT_XBAR Registers to Driverlib Functions.....	2727
19.4.5 MDL_XBAR Registers to Driverlib Functions.....	2728
19.4.6 ICL_XBAR Registers to Driverlib Functions.....	2729
19.4.7 XBAR Registers to Driverlib Functions.....	2729
19.4.8 XBAR Examples.....	2731
19.5 XBAR Registers.....	2731
19.5.1 XBAR Base Address Table.....	2731
19.5.2 INPUT_XBAR_REGS Registers.....	2733
19.5.3 EPWM_XBAR_REGS Registers.....	2741
19.5.4 CLB_XBAR_REGS Registers.....	2776
19.5.5 OUTPUTXBAR_REGS Registers.....	2804
19.5.6 MDL_XBAR_REGS Registers.....	2847
19.5.7 ICL_XBAR_REGS Registers.....	2860
19.5.8 OUTPUTXBAR_FLAG_REGS Registers.....	2873
19.5.9 XBAR_REGS Registers.....	2878
20 Embedded Pattern Generator (EPG).....	3005
20.1 Introduction.....	3006
20.1.1 Features.....	3006
20.1.2 EPG Block Diagram.....	3006
20.1.3 EPG Related Collateral.....	3007
20.2 Clock Generator Modules.....	3008
20.2.1 DCLK (50% duty cycle clock).....	3008
20.2.2 Clock Stop.....	3009
20.3 Signal Generator Module.....	3010
20.4 EPG Peripheral Signal Mux Selection.....	3013
20.5 Application Software Notes.....	3016
20.6 EPG Example Use Cases.....	3017
20.6.1 EPG Example: Synchronous Clocks with Offset.....	3017
20.6.2 EPG Example: Serial Data Bit Stream (LSB first).....	3018
20.6.3 EPG Example: Serial Data Bit Stream (MSB first).....	3019
20.6.4 EPG Example: Clock and Data Pair.....	3020
20.6.5 EPG Example: Clock and Skewed Data Pair.....	3021
20.6.6 EPG Example: Capturing Serial Data with a Known Baud Rate.....	3022
20.7 EPG Interrupt.....	3023
20.8 Software.....	3024
20.8.1 EPG Registers to Driverlib Functions.....	3024

20.8.2 EPG Examples.....	3025
20.9 EPG Registers.....	3026
20.9.1 EPG Base Address Table.....	3026
20.9.2 EPG_REGS Registers.....	3027
20.9.3 EPG_MUX_REGS Registers.....	3066
► ANALOG PERIPHERALS	3075
Technical Reference Manual Overview.....	3075
21 Analog Subsystem	3077
21.1 Introduction.....	3078
21.1.1 Features.....	3078
21.1.2 Block Diagram.....	3078
21.2 Optimizing Power-Up Time.....	3083
21.3 Digital Inputs on ADC Pins (AIOs).....	3084
21.4 Digital Inputs and Outputs on ADC Pins (AGPIOs).....	3085
21.5 Analog Pins and Internal Connections.....	3086
21.6 Software.....	3091
21.6.1 ASYSCTL Registers to Driverlib Functions.....	3091
21.7 Lock Registers.....	3092
21.8 ASBSYS Registers.....	3092
21.8.1 ASBSYS Base Address Table.....	3092
21.8.2 ANALOG_SUBSYS_REGS Registers.....	3093
22 Analog-to-Digital Converter (ADC)	3127
22.1 Introduction.....	3128
22.1.1 Features.....	3128
22.1.2 ADC Related Collateral.....	3129
22.1.3 Block Diagram.....	3130
ADC Glossary.....	3130
22.2 ADC Configurability.....	3134
22.2.1 ADC Clock Configuration.....	3134
22.2.2 Resolution.....	3134
22.2.3 Voltage Reference.....	3135
22.2.4 Signal Mode.....	3136
22.3 SOC Principle of Operation.....	3138
22.3.1 SOC Configuration.....	3139
22.3.2 Trigger Operation.....	3139
22.3.3 ADC Acquisition (Sample and Hold) Window.....	3150
22.3.4 ADC Input Models.....	3150
22.3.5 Channel Selection.....	3152
22.4 SOC Configuration Examples.....	3160
22.4.1 Single Conversion from ePWM Trigger.....	3160
22.4.2 Oversampled Conversion from ePWM Trigger.....	3160
22.4.3 Multiple Conversions from CPU Timer Trigger.....	3160
22.4.4 Software Triggering of SOC.....	3162
22.5 ADC Conversion Priority.....	3162
22.6 Burst Mode.....	3165
22.6.1 Burst Mode Example.....	3165
22.6.2 Burst Mode Priority Example.....	3166
22.7 EOC and Interrupt Operation.....	3167
22.7.1 Interrupt Overflow.....	3168
22.7.2 Continue to Interrupt Mode.....	3168
22.7.3 Early Interrupt Configuration Mode.....	3169
22.8 Post-Processing Blocks.....	3170
22.8.1 PPB Offset Correction.....	3171
22.8.2 PPB Error Calculation.....	3171
22.8.3 PPB Result Delta Calculation.....	3171
22.8.4 PPB Limit Detection and Zero-Crossing Detection.....	3172
22.8.5 PPB Oversampling.....	3175
22.9 Result Safety Checker.....	3176
22.9.1 Result Safety Checker Operation.....	3177
22.9.2 Result Safety Checker Interrupts and Events.....	3177
22.10 Opens/Shorts Detection Circuit (OSDETECT).....	3180

22.10.1 Open Short Detection Implementation.....	3181
22.10.2 Detecting an Open Input Pin.....	3181
22.10.3 Detecting a Shorted Input Pin.....	3181
22.11 Power-Up Sequence.....	3182
22.12 ADC Calibration.....	3182
22.12.1 ADC Zero Offset Calibration.....	3182
22.13 ADC Timings.....	3183
22.13.1 ADC Timing Diagrams.....	3183
22.13.2 Post-Processing Block Timings.....	3189
22.14 Additional Information.....	3191
22.14.1 Ensuring Synchronous Operation.....	3191
22.14.2 Choosing an Acquisition Window Duration.....	3195
22.14.3 Achieving Simultaneous Sampling.....	3197
22.14.4 Result Register Mapping.....	3197
22.14.5 Internal Temperature Sensor.....	3197
22.14.6 Designing an External Reference Circuit.....	3198
22.14.7 Internal Test Mode.....	3199
22.14.8 ADC Gain and Offset Calibration.....	3199
22.14.9 ADC Zero Offset Calibration.....	3200
22.15 Software.....	3201
22.15.1 ADC Registers to Driverlib Functions.....	3201
22.15.2 ADC Examples.....	3213
22.16 ADC Registers.....	3219
22.16.1 ADC Base Address Table.....	3219
22.16.2 ADC_RESULT_REGS Registers.....	3220
22.16.3 ADC_REGS Registers.....	3282
22.16.4 ADC_SAFECHECK_REGS Registers.....	3533
22.16.5 ADC_SAFECHECK_INTEVT_REGS Registers.....	3543
22.16.6 ADC_GLOBAL_REGS Registers.....	3595
23 Buffered Digital-to-Analog Converter (DAC).....	3601
23.1 Introduction.....	3602
23.1.1 DAC Related Collateral.....	3602
23.1.2 DAC Features.....	3602
23.1.3 Block Diagram.....	3602
23.2 Using the DAC.....	3603
23.2.1 Initialization Sequence.....	3603
23.2.2 DAC Offset Adjustment.....	3604
23.2.3 EPWMSYNCPER Signal.....	3604
23.3 Lock Registers.....	3604
23.4 Software.....	3605
23.4.1 DAC Registers to Driverlib Functions.....	3605
23.4.2 DAC Examples.....	3605
23.5 DAC Registers.....	3606
23.5.1 DAC Base Address Table.....	3606
23.5.2 DAC_REGS Registers.....	3607
24 Comparator Subsystem (CMPSS).....	3615
24.1 Introduction.....	3616
24.1.1 Features.....	3616
24.1.2 CMPSS Related Collateral.....	3616
24.1.3 Block Diagram.....	3616
24.2 Comparator.....	3617
24.3 Reference DAC.....	3618
24.4 Ramp Generator.....	3619
24.4.1 Ramp Generator Overview.....	3619
24.4.2 Ramp Generator Behavior.....	3620
24.4.3 Ramp Generator Behavior at Corner Cases.....	3621
24.5 Digital Filter.....	3623
24.5.1 Filter Initialization Sequence.....	3624
24.6 Using the CMPSS.....	3624
24.6.1 LATCHCLR, EPWMSYNCPER, and EPWMBLANK Signals.....	3624
24.6.2 Synchronizer, Digital Filter, and Latch Delays.....	3624

24.6.3 Calibrating the CMPSS	3625
24.6.4 Enabling and Disabling the CMPSS Clock.....	3625
24.7 Software.....	3626
24.7.1 CMPSS Registers to Driverlib Functions.....	3626
24.7.2 CMPSS Examples.....	3629
24.8 CMPSS Registers.....	3630
24.8.1 CMPSS Base Address Table.....	3630
24.8.2 CMPSS_REGS Registers.....	3631
► CONTROL PERIPHERALS	3676
Technical Reference Manual Overview.....	3676
25 Enhanced Capture (eCAP)	3678
25.1 Introduction.....	3679
25.1.1 ECAP Features.....	3679
25.1.2 ECAP Related Collateral.....	3679
25.2 Description.....	3680
25.3 Configuring Device Pins for the eCAP.....	3681
25.4 Capture and APWM Operating Mode.....	3687
25.5 Capture Mode Description.....	3690
25.5.1 Event Prescaler.....	3691
25.5.2 Glitch Filter.....	3692
25.5.3 Edge Polarity Select and Qualifier.....	3692
25.5.4 Continuous/One-Shot Control.....	3692
25.5.5 32-Bit Counter and Phase Control.....	3694
25.5.6 CAP1-CAP4 Registers.....	3694
25.5.7 eCAP Synchronization.....	3694
25.5.8 Interrupt Control.....	3695
25.5.9 RTDMA Interrupt	3698
25.5.10 ADC SOC Event.....	3698
25.5.11 Shadow Load and Lockout Control.....	3698
25.5.12 APWM Mode Operation.....	3698
25.5.13 Signal Monitoring Unit.....	3700
25.6 Application of the eCAP Module.....	3706
25.6.1 Example 1 - Absolute Time-Stamp Operation Rising-Edge Trigger.....	3706
25.6.2 Example 2 - Absolute Time-Stamp Operation Rising- and Falling-Edge Trigger.....	3707
25.6.3 Example 3 - Time Difference (Delta) Operation Rising-Edge Trigger.....	3708
25.6.4 Example 4 - Time Difference (Delta) Operation Rising- and Falling-Edge Trigger.....	3709
25.7 Application of the APWM Mode.....	3710
25.7.1 Example 1 - Simple PWM Generation (Independent Channels).....	3710
25.8 Software.....	3711
25.8.1 ECAP Registers to Driverlib Functions.....	3711
25.8.2 ECAP Examples.....	3713
25.9 ECAP Registers.....	3715
25.9.1 ECAP Base Address Table.....	3715
25.9.2 ECAP_REGS Registers.....	3716
25.9.3 ECAP_SIGNAL_MONITORING Registers.....	3738
25.9.4 HRCAP_REGS Registers.....	3757
26 High Resolution Capture (HRCAP)	3769
26.1 Introduction.....	3770
26.1.1 HRCAP Related Collateral.....	3770
26.1.2 Features.....	3770
26.1.3 Description.....	3770
26.2 Operational Details.....	3771
26.2.1 HRCAP Clocking.....	3772
26.2.2 HRCAP Initialization Sequence.....	3772
26.2.3 HRCAP Interrupts.....	3772
26.2.4 HRCAP Calibration.....	3773
26.3 Known Exceptions.....	3774
26.4 Software.....	3775
26.4.1 HRCAP Examples.....	3775
26.5 HRCAP Registers.....	3775
26.5.1 HRCAP Base Address Table.....	3775

26.5.2 HRCAP_REGS Registers.....	3776
27 Enhanced Pulse Width Modulator (ePWM).....	3788
27.1 Introduction.....	3789
27.1.1 EPWM Related Collateral.....	3791
27.1.2 Submodule Overview.....	3791
27.2 Configuring Device Pins.....	3797
27.3 ePWM Modules Overview.....	3797
27.4 Time-Base (TB) Submodule.....	3799
27.4.1 Purpose of the Time-Base Submodule.....	3799
27.4.2 Controlling and Monitoring the Time-Base Submodule.....	3800
27.4.3 Calculating PWM Period and Frequency.....	3802
27.4.4 Phase Locking the Time-Base Clocks of Multiple ePWM Modules.....	3807
27.4.5 XLINK Feature.....	3807
27.4.6 Simultaneous Writes to TBPRD and CMPx Registers Between ePWM Modules (Legacy XLINK scheme)	3808
27.4.7 Simultaneous Writes Between ePWM Register Instances (Type-5 XLINK scheme)	3808
27.4.8 Time-Base Counter Modes and Timing Waveforms.....	3809
27.4.9 Global Load.....	3813
27.5 Counter-Compare (CC) Submodule.....	3815
27.5.1 Purpose of the Counter-Compare Submodule.....	3815
27.5.2 Controlling and Monitoring the Counter-Compare Submodule.....	3816
27.5.3 Operational Highlights for the Counter-Compare Submodule.....	3817
27.5.4 Count Mode Timing Waveforms.....	3818
27.6 Action-Qualifier (AQ) Submodule.....	3821
27.6.1 Purpose of the Action-Qualifier Submodule.....	3821
27.6.2 Action-Qualifier Submodule Control and Status Register Definitions.....	3822
27.6.3 Action-Qualifier Event Priority.....	3824
27.6.4 AQCTLA and AQCTLB Shadow Mode Operations.....	3825
27.6.5 Configuration Requirements for Common Waveforms.....	3828
27.7 XCMP Complex Waveform Generator Mode.....	3834
27.7.1 XCMP Allocation to CMPA and CMPB.....	3835
27.7.2 XCMP Shadow Buffers.....	3836
27.7.3 XCMP Operation.....	3838
27.8 Dead-Band Generator (DB) Submodule.....	3841
27.8.1 Purpose of the Dead-Band Submodule.....	3841
27.8.2 Dead-band Submodule Additional Operating Modes.....	3842
27.8.3 Operational Highlights for the Dead-Band Submodule.....	3844
27.9 PWM Chopper (PC) Submodule.....	3848
27.9.1 Purpose of the PWM Chopper Submodule.....	3848
27.9.2 Operational Highlights for the PWM Chopper Submodule.....	3848
27.9.3 Waveforms.....	3849
27.10 Trip-Zone (TZ) Submodule.....	3852
27.10.1 Purpose of the Trip-Zone Submodule.....	3852
27.10.2 Operational Highlights for the Trip-Zone Submodule.....	3853
27.10.3 Generating Trip Event Interrupts.....	3856
27.11 Diode Emulation (DE) Submodule.....	3859
27.11.1 DEACTIVE Mode.....	3863
27.11.2 Exiting DE Mode.....	3864
27.11.3 Re-Entering DE Mode.....	3864
27.11.4 DE Monitor	3866
27.12 Minimum Dead-Band (MINDB) + Illegal Combination Logic (ICL) Submodules.....	3867
27.12.1 Minimum Dead-Band (MINDB).....	3868
27.12.2 Illegal Combo Logic (ICL).....	3870
27.13 Event-Trigger (ET) Submodule.....	3871
27.13.1 Operational Overview of the ePWM Event-Trigger Submodule.....	3872
27.14 Digital Compare (DC) Submodule.....	3876
27.14.1 Purpose of the Digital Compare Submodule.....	3878
27.14.2 Enhanced Trip Action Using CMPSS.....	3878
27.14.3 Using CMPSS to Trip the ePWM on a Cycle-by-Cycle Basis.....	3878
27.14.4 Operation Highlights of the Digital Compare Submodule.....	3879
27.15 ePWM Crossbar (X-BAR).....	3891
27.16 Applications to Power Topologies.....	3892

27.16.1 Overview of Multiple Modules.....	3892
27.16.2 Key Configuration Capabilities.....	3893
27.16.3 Controlling Multiple Buck Converters With Independent Frequencies.....	3894
27.16.4 Controlling Multiple Buck Converters With Same Frequencies.....	3896
27.16.5 Controlling Multiple Half H-Bridge (HHB) Converters.....	3898
27.16.6 Controlling Dual 3-Phase Inverters for Motors (ACI and PMSM).....	3900
27.16.7 Practical Applications Using Phase Control Between PWM Modules.....	3902
27.16.8 Controlling a 3-Phase Interleaved DC/DC Converter.....	3903
27.16.9 Controlling Zero Voltage Switched Full Bridge (ZVSFB) Converter.....	3906
27.16.10 Controlling a Peak Current Mode Controlled Buck Module.....	3908
27.16.11 Controlling H-Bridge LLC Resonant Converter.....	3909
27.17 Register Lock Protection.....	3910
27.18 High-Resolution Pulse Width Modulator (HRPWM).....	3911
27.18.1 Operational Description of HRPWM.....	3913
27.18.2 SFO Library Software - SFO_TI_Build_V8.lib	3934
27.19 Software.....	3937
27.19.1 EPWM Registers to Driverlib Functions.....	3937
27.19.2 HRPWMCAL Registers to Driverlib Functions.....	3949
27.19.3 EPWM Examples.....	3949
27.19.4 HRPWM Examples.....	3956
27.20 EPWM Registers.....	3957
27.20.1 EPWM Base Address Table.....	3958
27.20.2 EPWM_REGS Registers.....	3963
27.20.3 EPWM_XCMP_REGS Registers.....	4109
27.20.4 DE_REGS Registers.....	4182
27.20.5 MINDB_LUT_REGS Registers.....	4193
27.20.6 HRPWMCAL_REGS Registers.....	4201
28 Enhanced Quadrature Encoder Pulse (eQEP).....	4204
28.1 Introduction.....	4205
28.1.1 EQEP Related Collateral.....	4207
28.2 Configuring Device Pins.....	4207
28.3 Description.....	4208
28.3.1 EQEP Inputs.....	4208
28.3.2 Functional Description.....	4210
28.3.3 eQEP Memory Map.....	4211
28.4 Quadrature Decoder Unit (QDU).....	4212
28.4.1 Position Counter Input Modes.....	4212
28.4.2 eQEP Input Polarity Selection.....	4215
28.4.3 Position-Compare Sync Output.....	4215
28.5 Position Counter and Control Unit (PCCU).....	4215
28.5.1 Position Counter Operating Modes.....	4215
28.5.2 Position Counter Latch.....	4218
28.5.3 Position Counter Initialization.....	4220
28.5.4 eQEP Position-compare Unit.....	4221
28.6 eQEP Edge Capture Unit.....	4223
28.7 eQEP Watchdog.....	4227
28.8 eQEP Unit Timer Base.....	4228
28.9 QMA Module.....	4229
28.9.1 Modes of Operation.....	4230
28.9.2 Interrupt and Error Generation.....	4231
28.10 eQEP Interrupt Structure.....	4232
28.11 Software.....	4233
28.11.1 EQEP Registers to Driverlib Functions.....	4233
28.11.2 EQEP Examples.....	4234
28.12 EQEP Registers.....	4236
28.12.1 EQEP Base Address Table.....	4236
28.12.2 EQEP_REGS Registers.....	4237
29 Sigma Delta Filter Module (SDFM).....	4275
29.1 Introduction.....	4276
29.1.1 SDFM Related Collateral.....	4276
29.1.2 Features.....	4277

29.1.3 Block Diagram.....	4278
29.2 Configuring Device Pins.....	4280
29.3 Input Qualification.....	4281
29.4 Input Control Unit.....	4282
29.5 SDFM Clock Control.....	4282
29.6 Sinc Filter.....	4283
29.6.1 Data Rate and Latency of the Sinc Filter.....	4285
29.7 Data (Primary) Filter Unit.....	4286
29.7.1 32-bit or 16-bit Data Filter Output Representation.....	4287
29.7.2 Data FIFO.....	4287
29.7.3 SDSYNC Event.....	4289
29.8 Comparator (Secondary) Filter Unit.....	4292
29.8.1 Higher Threshold (HLT) Comparators	4294
29.8.2 Lower Threshold (LLT) Comparators	4294
29.8.3 Digital Filter.....	4295
29.9 Theoretical SDFM Filter Output.....	4296
29.10 Interrupt Unit.....	4298
29.10.1 SDFM (SDyERR) Interrupt Sources	4298
29.10.2 Data Ready (DRINT) Interrupt Sources.....	4299
29.11 SDFM Registers.....	4300
29.11.1 SDFM Base Address Table.....	4300
29.11.2 SDFM_REGS Registers.....	4301
► COMMUNICATION PERIPHERALS	4397

31.6.3 ESCSS_CONFIG_REGS Registers.....	4625
32 Fast Serial Interface (FSI).....	4635
32.1 Introduction.....	4636
32.1.1 FSI Related Collateral.....	4636
32.1.2 FSI Features.....	4636
32.2 System-level Integration.....	4637
32.2.1 CPU Interface.....	4637
32.2.2 Signal Description.....	4639
32.2.3 FSI Interrupts.....	4640
32.2.4 RTDMA Interface.....	4642
32.2.5 External Frame Trigger Mux.....	4643
32.3 FSI Functional Description.....	4645
32.3.1 Introduction to Operation.....	4645
32.3.2 FSI Transmitter Module.....	4646
32.3.3 FSI Receiver Module.....	4652
32.3.4 Frame Format.....	4658
32.3.5 Flush Sequence.....	4662
32.3.6 Internal Loopback.....	4662
32.3.7 CRC Generation.....	4663
32.3.8 ECC Module.....	4664
32.3.9 Tag Matching.....	4665
32.3.10 User Data Filtering (UDATA Matching).....	4665
32.3.11 TDM Configurations.....	4665
32.3.12 FSI Trigger Generation.....	4668
32.3.13 FSI-SPI Compatibility Mode.....	4670
32.4 FSI Programing Guide.....	4674
32.4.1 Establishing the Communication Link.....	4674
32.4.2 Register Protection.....	4676
32.4.3 Emulation Mode.....	4676
32.5 Software.....	4677
32.5.1 FSI Registers to Driverlib Functions.....	4677
32.5.2 FSI Examples.....	4681
32.5.3 FSI Examples.....	4681
32.6 FSI Registers.....	4682
32.6.1 FSI Base Address Table.....	4682

32.6.2 FSI_TX_REGS Registers.....	4683
32.6.3 FSI_RX_REGS Registers.....	4710
33 Inter-Integrated Circuit Module (I2C).....	4759
33.1 Introduction.....	4760
33.1.1 I2C Related Collateral.....	4760
33.1.2 Features.....	4761
33.1.3 Features Not Supported.....	4761
33.1.4 Functional Overview.....	4762
33.1.5 Clock Generation.....	4763
33.1.6 I2C Clock Divider Registers (I2CCLKL and I2CCLKH).....	4764
33.2 Configuring Device Pins.....	4765
33.3 I2C Module Operational Details.....	4765
33.3.1 Input and Output Voltage Levels.....	4765
33.3.2 Selecting Pullup Resistors.....	4765
33.3.3 Data Validity.....	4765
33.3.4 Operating Modes.....	4766
33.3.5 I2C Module START and STOP Conditions.....	4770
33.3.6 Non-repeat Mode versus Repeat Mode.....	4771
33.3.7 Serial Data Formats.....	4771
33.3.8 Clock Synchronization.....	4774
33.3.9 Clock Stretching.....	4775
33.3.10 Arbitration.....	4777
33.3.11 Digital Loopback Mode.....	4778
33.3.12 NACK Bit Generation.....	4779
33.4 Interrupt Requests Generated by the I2C Module.....	4779
33.4.1 Basic I2C Interrupt Requests.....	4780
33.4.2 I2C FIFO Interrupts.....	4784
33.5 Resetting or Disabling the I2C Module.....	4784
33.6 Software.....	4785
33.6.1 I2C Registers to Driverlib Functions.....	4785
33.6.2 I2C Examples.....	4786
33.7 I2C Registers.....	4788
33.7.1 I2C Base Address Table.....	4788
33.7.2 I2C_REGS Registers.....	4789
34 Power Management Bus Module (PMBus).....	4813
34.1 Introduction.....	4814
34.1.1 PMBUS Related Collateral.....	4814
34.1.2 Features.....	4814
34.1.3 Block Diagram.....	4815
34.2 Configuring Device Pins.....	4816
34.3 Target Mode Operation.....	4816
34.3.1 Configuration.....	4816
34.3.2 Message Handling.....	4817
34.4 Controller Mode Operation.....	4827
34.4.1 Configuration.....	4827
34.4.2 Message Handling.....	4827
34.5 Software.....	4838
34.5.1 PMBUS Registers to Driverlib Functions.....	4838
34.5.2 PMBUS Examples.....	4839
34.6 PMBUS Registers.....	4840
34.6.1 PMBUS Base Address Table.....	4840
34.6.2 PMBUS_REGS Registers.....	4841
35 Universal Asynchronous Receiver/Transmitter (UART).....	4862
35.1 Introduction.....	4863
35.1.1 Features.....	4863
35.1.2 UART Related Collateral.....	4863
35.1.3 Block Diagram.....	4864
35.2 Functional Description.....	4865
35.2.1 Transmit and Receive Logic.....	4865
35.2.2 Baud-Rate Generation.....	4866
35.2.3 Data Transmission.....	4867

35.2.4 Serial IR (SIR).....	4867
35.2.5 9-Bit UART Mode.....	4868
35.2.6 FIFO Operation.....	4869
35.2.7 Interrupts.....	4869
35.2.8 Loopback Operation.....	4870
35.2.9 RTDMA Operation	4870
35.3 Initialization and Configuration.....	4872
35.4 Software.....	4873
35.4.1 UART Registers to Driverlib Functions.....	4873
35.4.2 UART Examples.....	4875
35.5 UART Registers.....	4877
35.5.1 UART Base Address Table.....	4877
35.5.2 UART_REGS Registers.....	4879
35.5.3 UART_REGS_WRITE Registers.....	4921
36 Local Interconnect Network (LIN).....	4923
36.1 LIN Overview.....	4924
36.1.1 LIN Mode Features.....	4924
36.1.2 SCI Mode Features.....	4925
36.1.3 Block Diagram.....	4926
36.2 Serial Communications Interface Module.....	4929
36.2.1 SCI Communication Formats.....	4929
36.2.2 SCI Interrupts.....	4939
36.2.3 SCI RTDMA Interface	4943
36.2.4 SCI Configurations.....	4944
36.2.5 SCI Low-Power Mode.....	4946

About This Manual

This Technical Reference Manual (TRM) details the integration, the environment, the functional description, and the programming models for each peripheral and subsystem in the device.

The TRM should not be considered a substitute for the data sheet, rather a companion guide that can be used alongside the device-specific data sheet to understand the details to program the device. The primary purpose of the TRM is to abstract the programming details of the device from the data sheet. This allows the data sheet to outline the high-level features of the device without unnecessary information about register descriptions or programming models.

Note

Texas Instruments is transitioning to use more inclusive terminology. Some language may be different than what you would expect to see for certain technology areas.

Notational Conventions

This document uses the following conventions.

- Hexadecimal numbers can be shown with the suffix h or the prefix 0x. For example, the following number is 40 hexadecimal (decimal 64): 40h or 0x40.
- Registers in this document are shown in figures and described in tables.
 - Each register figure shows a rectangle divided into fields that represent the fields of the register. Each field is labeled with its bit name, its beginning and ending bit numbers above, and its read/write properties with default reset value below. A legend explains the notation used for the properties.
 - Reserved bits in a register figure can have one of multiple meanings:
 - Not implemented on the device
 - Reserved for future device expansion
 - Reserved for TI testing
 - Reserved configurations of the device that are not supported
 - Writing nondefault values to the Reserved bits could cause unexpected behavior and should be avoided.

Glossary

[TI Glossary](#) This glossary lists and explains terms, acronyms, and definitions.

► C29x SYSTEM RESOURCES

The following chapters describe the C29x Configuration and System Resources.

Technical Reference Manual Overview

The block diagram is shown in [Block Diagram](#). This Technical Reference Manual is organized into five major sections:

- [C29x SYSTEM RESOURCES](#)

These chapters describe the C29x CPU subsystem, C29x Boot ROM, device configuration, and other system peripherals.

- [ANALOG PERIPHERALS](#)

These chapters describe the general analog subsystem configuration, Analog-to-Digital Converter (ADC), Buffered Digital-to-Analog Converter (DAC), and Comparator Subsystem (CMPSS).

- [CONTROL PERIPHERALS](#)

These chapters describe the Enhanced Capture (eCAP), High-Resolution Capture (HRCAP), Enhanced Pulse-Width Modulator (ePWM) with High-Resolution Pulse-Width Modulator (HRPWM), Enhanced Quadrature Encoder Pulse (eQEP), and Sigma Delta Filter Module (SDFM) peripherals.

- [COMMUNICATION PERIPHERALS](#)

These chapters describe the communication peripherals available to the C29x subsystem such as the EtherCAT, FSI, I2C, PMBUS, UART, LIN, SPI, and SENT.

- [SECURITY PERIPHERALS](#)

This chapter describes the safety peripherals available to the C29x subsystem such as the Hardware Security Module (HSM) and Cryptographic Accelerator.

Block Diagram

This chapter contains a short description of the C29x processor.

Further information can be found in the following documents:

- [C29x CPU Reference Guide](#)
- [Accelerators: Enhancing the Capabilities of the C2000 MCU Family Technical Brief](#)

1.1 CPU Architecture.....	134
1.2 Lock and Commit Registers.....	135
1.3 C29x CPU Registers.....	136

1.1 CPU Architecture

The CPU is a VLIW (Very-Long Instruction Word) architecture with a fully protected pipeline. The CPU supports multiple instruction sizes (16/32/48 bits). The CPU also supports variable instruction packet size, with each packet able to contain up to eight instructions that execute in parallel. For example, the CPU architecture can execute up to eight 16-bit instructions in parallel. This is enabled by multiple functional units inside the CPU which can execute concurrently. A total of 64 working registers, broken into three different categories (Ax, Dx, and Mx Register banks) support the parallel operations in the CPU. In addition to the working registers, the CPU contains multiple status registers (DSTS, ESTS, and ISTS) that maintain execution-related and interrupt-context-related information.

Following are the list of CPU major features:

- **Ease of use:**
 - Byte addressable CPU.
 - Linear and unified memory map with 4 GB address range.
 - Fully Protected Pipeline: 9 stage pipeline that prevents writes and reads from same location from occurring out of order.
 - Deterministic execution and maximum performance without cached memories.
- **Improved parallelism:**
 - Execute from 1 to 8 instructions in parallel.
 - Execute fixed-point, floating-point, and addressing operations in parallel.
 - Multiple parallel functional units.
 - Specialized operations to minimize discontinuities and accelerate decision making code (for example, if-then-else statements and switch statements).
 - Specialized operations targeting real-time control (for example, trigonometric operations and multiphase vector translation operations).
- **Improved bus throughput:**
 - Capable of fetching up to 128-bit instruction packet every cycle.
 - Capable of performing 8/16/32/64-bit dual reads and single writes per cycle.
 - Improved addressing modes reduce overhead in accessing memory and peripheral resources.
 - Improved pipeline allows for additional 0-wait memory to be accessible to CPU for max performance.
- **Code efficiency:**
 - Supports variable length instruction set (16-bit, 32-bit, and 48-bit instructions).
 - Rich instruction set optimizes the most common operations in smallest instructions.
- **ASIL-D safety capability with code isolation in hardware:**
 - Lock step core capable of independent execution in split-lock mode (acting as a separate core) or lock step execution (for redundancy).
 - Integrated ECC logic
 - Integrated memory management (MPU) and protection mechanisms in hardware to maximize MIPS.
 - Separate code threads are fully isolated and protected (including software stacks).
- **Multizone security in hardware:**
 - Run time content protection and IP protection of code.
 - Individual passwords for each zone to control access.
- **Enhanced debug and trace capabilities:**
 - Specialized data logging and code flow trace instructions.
 - Trace data capable of being logged in on-chip RAM or exported through serial communication peripherals.

The following block diagram showcases the C29 CPU Architecture.

1.2 Lock and Commit Registers

The Lock and Commit mechanisms are provided for various device registers to prevent unintentional or spurious writes to the critical registers.

Texas Instruments highly recommends that users lock the SECCALL and RTINT stack memory-mapped registers using the C29_REGS_LOCK register for fault avoidance from safety aspect and also commit the lock

registers using the C29_REGS_COMMIT register for additional security so that registers are not altered during runtime. This can be done at initialization.

1.3 C29x CPU Registers

This section describes the C29x CPU Registers.

1.3.1 C29CPU Base Address Table

Table 1-1. C29CPU Base Address Table

Structure	DriverLib Name	Base Address	Frame Applicable	CPU1	CPU2	CPU3	RTDMA1	RTDMA2	HSM	Pipeline Protected
C29_RTINT_STACK	C29CPURTINTSTACK_BASE	0x3000_8000	-	YES	YES	YES	-	-	-	YES
C29_SECCALL_STACK	C29CPUSECCALLSTACK_BASE	0x3000_C000	-	YES	YES	YES	-	-	-	YES
C29_SECURE_REGS	C29CPUSECURE_BASE	0x3000_D000	-	YES	YES	YES	-	-	-	YES
C29_DIAG_REGS	C29CPUDIAG_BASE	0x3000_E000	-	YES	YES	YES	-	-	-	YES
C29_SELFTEST_REGS	C29CPUSELFTEST_BASE	0x3000_F000	-	YES	YES	YES	-	-	-	YES

1.3.2 C29_RTINT_STACK Registers

Table 1-2 lists the memory-mapped registers for the C29_RTINT_STACK registers. All register offset addresses not listed in Table 1-2 should be considered as reserved locations and the register contents should not be modified.

Table 1-2. C29_RTINT_STACK Registers

Offset	Acronym	Register Name	Protection
0h + formula	RTINT_STACK_DATA0_j	RTINT stack Data0	
4h + formula	RTINT_STACK_DATA1_j	RTINT stack Data1	
8h + formula	RTINT_STACK_DATA2_j	RTINT stack Data2	
Ch + formula	RTINT_STACK_DATA3_j	RTINT stack Data3	
10h + formula	RTINT_STACK_DATA4_j	RTINT stack Data4	
14h + formula	RTINT_STACK_DATA5_j	RTINT stack Data5	
18h + formula	RTINT_STACK_DATA6_j	RTINT stack Data6	
1Ch + formula	RTINT_STACK_DATA7_j	RTINT stack Data7	
20h + formula	RTINT_STACK_DATA8_j	RTINT stack Data8	
24h + formula	RTINT_STACK_ECC0_j	RTINT stack ECC0	
28h + formula	RTINT_STACK_ECC1_j	RTINT stack ECC1	
2Ch + formula	RTINT_STACK_ECC2_j	RTINT stack ECC2	
30h + formula	RTINT_STACK_ECC3_j	RTINT stack ECC3	

Complex bit access types are encoded to fit into small table cells. Table 1-3 shows the codes that are used for access types in this section.

Table 1-3. C29_RTINT_STACK Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

1.3.2.1 RTINT_STACK_DATA0_j Register (Offset = 0h + formula) [Reset = 00000000h]

1.3.4 C29_SECURE_REGS Registers

Table 1-22 lists the memory-mapped registers for the C29_SECURE_REGS registers. All register offset addresses not listed in Table 1-22 should be considered as reserved locations and the register contents should not be modified.

Table 1-22. C29_SECURE_REGS Registers

Offset	Acronym	Register Name	Protection
0h	SECSP0	Secure Stackpointer 0	
4h	SECSP1	Secure Stackpointer 1	
8h	SECSP2	Secure Stackpointer 2	
Ch	SECSP3	Secure Stackpointer 3	
10h	SECSP4	Secure Stackpointer 4	
14h	SECSP5	Secure Stackpointer 5	
18h	SECSP6	Secure Stackpointer 6	
1Ch	SECSP7	Secure Stackpointer 7	
80h	PSP	Protected call stack pointer	
84h	WARNPSP	Warning level register for protected call stack pointer	
88h	MAXPSP	Maximum levels of protected calls supported by the HW	
8Ch	REVISION	IP revision id register	
90h	C29_REGS_LOCK	Lock register	
94h	C29_REGS_COMMIT	Commit register	

Complex bit access types are encoded to fit into small table cells. Table 1-23 shows the codes that are used for access types in this section.

Table 1-23. C29_SECURE_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

1.3.4.1 SECSP0 Register (Offset = 0h) [Reset = 00000000h]

1.3.6 C29_SELFTEST_REGS Registers

Table 1-45 lists the memory-mapped registers for the C29_SELFTEST_REGS registers. All register offset addresses not listed in Table 1-45 should be considered as reserved locations and the register contents should not be modified.

Table 1-45. C29_SELFTEST_REGS Registers

Offset	Acronym	Register Name	Protection
0h	SELFTEST_DIAG_DATA0	Diagnostics data register 0	
4h	SELFTEST_DIAG_DATA1	Diagnostics data register 1	
8h	SELFTEST_DIAG_DATA2	Diagnostics data register 2	
20h	SELFTEST_DIAG_ECC	Diagnostics ECC	
28h	SELFTEST_DIAG_CONTROL	Diagnostic test enable	
2Ch	SELFTEST_DIAG_STATUS	Diagnostic status register	
30h	SELFTEST_DIAG_STATUS_CLR	Diagnostic status clear register	

Complex bit access types are encoded to fit into small table cells. Table 1-46 shows the codes that are used for access types in this section.

Table 1-46. C29_SELFTEST_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

1.3.6.1 SELFTEST_DIAG_DATA0 Register (Offset = 0h) [Reset = 00000000h]

Chapter 2

System Control and Interrupts

This chapter explains system control and interrupts for the C29x cores found on this MCU. The system control module configures and manages the overall operation of the device, and provides information about the device status. The details relating to system control include various sections like reset control, bus architecture, power control, clock control, low-power modes and memory controller subsystem.

2.1 C29x System Control Introduction	188
2.2 System Control Functional Description	188

2.9 Watchdog Timers	212
2.10 Low-Power Modes	215
2.11 Memory Subsystem (MEMSS)	216
2.12 System Control Register Configuration Restrictions	239
2.13 Device Initialization Software Sequence	239
2.14 Software	243
2.15 SYSCTRL Registers	270

2.1 C29x System Control Introduction

On this device, the CPU1 subsystem acts as a controller, and by default (upon reset), the CPU1 subsystem owns all the configuration and control. Through software running on CPU1, peripherals and I/Os can be configured to be accessible by the other CPU subsystems and the chosen configurations can be locked.

The PLL clock configuration is also owned by the CPU1 subsystem by default and HSM subsystem can also access clock configuration if permissions are enabled (by default enabled).

Each CPU can be independently configured to accept interrupts from different peripherals. The interrupt path is divided into three stages – the peripheral (in some cases ESM also), the PIPE, and the CPU. All stages must be configured and enabled for an interrupt to propagate to the CPU.

Each CPU has an NMI module to handle different exceptions during run time. If the NMI was on CPU1, any NMI exception that is not handled before the NMI Watchdog (ESM NMIWD) timer expiration resets the entire device using XRSn. If the NMI was on any other CPU subsystem, then the specific CPU subsystem is reset (or the entire device is reset depending on the configuration) and all other CPU subsystems can be informed using ESM that the CPU subsystem was reset because of NMIWD timer expiration.

Each CPU subsystem has a watchdog timer module for software to use. Watchdog timer expiration on CPU1 resets the entire device and Watchdog timer expiration on other CPU resets that specific CPU subsystem alone when configured to generate a reset.

The register space of the device system control module can be found in [Section 2.15](#).

This chapter explains the system control module on all the CPU subsystems.

2.2 System Control Functional Description

The system control module provides the following capabilities:

- Device identification and configuration registers
- Reset control
- Exceptions and Interrupt control (Refer to [Chapter 5](#))
- Safety and error handling features of the device
- Power control
- Clock control
- Low-power modes
- Bus Architecture
- Memory Controller Subsystem

2.2.1 Device Identification

Device identification registers provide information on device class, device family, revision, part number, pin count, and device qualification status.

All of the device information is part of the DEV_CFG_REGS space and is accessible only by the software running on the CPU1 subsystem.

The F29x device identification registers are: PARTIDL, PARTIDH, and REVID.

The Unique ID (UID) is available in SOCID information stored at M0 RAM location 0x2000_0980.

2.2.2 Device Configuration Registers

Several registers provide users with configuration information for the C29x subsystems for debug and identification purposes. This information includes the features of the peripherals and how much RAM and Flash memory is available on this part.

These registers are part of DEV_CFG_REGS space and are writable only by the software running on the CPU1.LINK0, CPU1.LINK1, and CPU1.LINK2. All other CPUs can read these registers in all links.

- MCUCNFx: MCU Configuration registers have been implemented to enable customers to emulate a sub-set device on a super-set device. The following function is provided to configure the device accordingly:

```
sysCtl_emulateDevice( SysCtl_DevicePartNumber partNumber )
```

- CPUID: CPU identification register. This register is available for software to identify on which CPU the register is executing.

2.3 Resets

This section explains the types and effects of the different resets on this device.

2.3.1 Reset Sources

Table 2-1 summarizes the various reset signals and the effect on the device.

Table 2-1. Reset Signals

Reset Source	LPOST	HSM Reset	CPU1 Subsystem Reset	CPU2 Subsystem Reset	CPU3 Subsystem Reset	JTAG / Debug Logic Reset	IOs	XRSn Output
PORESETn_RAW	Yes	Yes	Yes	Yes	Yes	Yes	Hi-Z	Yes
PORESETn	-	Yes	Yes	Yes	Yes	Yes	Hi-Z	Yes
XRSn Pin	-	Yes	Yes	Yes	Yes	-	Hi-Z	-
CPU1.SIMRESET.XRSn	-	Yes	Yes	Yes	Yes	-	Hi-Z	Yes
CPU1.WDRSn	-	Yes	Yes	Yes	Yes	-	Hi-Z	Yes
ESM CPU1.NMIWDRSn	-	Yes	Yes	Yes	Yes	-	Hi-Z	Yes
CPU1.SYSRSn (Debugger Reset)	-	-	Yes	Yes	Yes	-	Hi-Z	-
CPU2.WDRSn	-	-	-	Yes	-	-	-	-
ESM CPU2.NMIWDRSn ⁽¹⁾	-	Yes	Yes	Yes	Yes	-	Hi-Z	Yes
CPU2.SYSRSn (Debugger Reset)	-	-	-	Yes	-	-	-	-
CPU3.WDRSn	-	-	-	-	Yes	-	-	-
ESM CPU3.NMIWDRSn ⁽¹⁾	-	Yes	Yes	Yes	Yes	-	Hi-Z	Yes
CPU3.SYSRSn (Debugger Reset)	-	-	-	-	Yes	-	-	-
ECAT_RESET_OUT	-	Yes	Yes	Yes	Yes	-	Hi-Z	Yes

(1) Applicable only if ESM CPU instances are programmed in ESMXRSNCTL register to trigger XRSn. Refer to Chapter 7 for more details.

Note

After a reset, the reset cause register (RESC) is updated with the reset cause. The bits in this register maintain the state across multiple resets. These can only be cleared by a power-on reset (POR) or by writing 1 to the corresponding bit in RESCCLR register. Each CPU has an RESC register, referred to as CPU1.RESC, CPU2.RESC and CPU3.RESC.

The resets can be divided into a few groups:

- Chip-level resets (XRSn, PORESETn, CPU1.WDRSn, ESM CPU1.NMIWDRSn, ESM CPU2.NMIWDRSn (if enabled to trigger XRSn), ESM CPU3.NMIWDRSn (if enabled to trigger XRSn), SIMRESET.XRSn and ECAT_RESET_OUT (if enabled)), which reset all or almost all of the device.
- System resets (CPU1.SYSRS), which reset a large subset of the device but maintain some system-level configuration.
- CPU2 subsystem resets (CPU2.SYSRSn, CPU2.WDRSn, ESM CPU2.NMIWDRSn (if configured to trigger CPU3.RSn)), which reset only CPU2 and the peripherals.
- CPU3 subsystem resets (CPU3.SYSRSn, CPU3.WDRSn, ESM CPU3.NMIWDRSn (if configured to trigger CPU3.RSn)), which reset only CPU3 and the peripherals.

Whenever the CPU1 subsystem is reset, CPU2 and CPU3 also gets reset if configured in SSU CPU2 and CPU3 Reset Control (CPU_RST_CTRL) registers and held in reset until CPU1 brings CPU2 and CPU3 out of reset by writing to the CPU_RST_CTRL register or as determined by HSM input. This is done by user application code on CPU1.

Many peripheral modules have individual resets accessible through the system control registers. For information about a module reset state, refer to the appropriate chapter for that module.

Note

After a POR, the boot ROMs clears and initializes all of the RAMs.

[Figure 2-1](#) captures the overall device level reset connectivity and propagation.

Figure 2-1. Device Reset Diagram

2.3.2 External Reset ($\overline{\text{XRS}}$)

The external reset ($\overline{\text{XRS}}$) is the main chip-level reset for the device. $\overline{\text{XRS}}$ resets all C29x CPUs, HSM, all peripherals and I/O pin configurations, and most of the system control registers. $\overline{\text{XRS}}$ also holds CPU2, CPU3 and HSM in reset. There is a dedicated open-drain pin for $\overline{\text{XRS}}$. This pin can be used to drive reset pins for other ICs in the application, and can be driven by an external source. The $\overline{\text{XRS}}$ is driven internally during watchdog, NMI, and power-on resets.

The XRSn bit in the RESC register is set whenever $\overline{\text{XRS}}$ is driven low for any reason. This bit is then cleared by the boot ROM.

2.3.3 Simulate External Reset

The user can simulate an external reset ($\overline{\text{XRS}}$) by setting the XRSn bit to 1 in the SIMRESET register using CPU1 software. This toggles the $\overline{\text{XRS}}$ pin; hence, resetting the full device (just like an external reset).

After this reset, the SIMRESET_XRSn bit in the RESC register is set. Software can read this bit to know the cause of the reset and clear the status by writing a 1 into the corresponding bit in the RESCCLR register.

2.3.4 Power-On Reset (POR)

The power-on reset (POR) circuit creates a clean reset throughout the device during power-up, suppressing glitches on the GPIOs. The $\overline{XRS}$ pin is held low for the duration of the POR. In most applications, $\overline{XRS}$ is held low long enough to reset other system ICs, but some applications can require a longer pulse. In these cases, $\overline{XRS}$ can be driven low externally to provide the correct reset duration. A POR resets everything that $\overline{XRS}$ does, along with the register – the reset cause register (RESC).

After a POR, the POR and XRSn bits in RESC are set. These bits are then cleared by the boot ROM.

2.3.5 Debugger Reset ($\overline{SYSRS}$)

During development, resetting the CPU and the peripherals without disconnecting the debugger or disrupting the system-level configuration can be necessary. To facilitate this, each CPU has a subsystem reset, which can be triggered by a debugger using Code Composer Studio™ IDE. CPU2 subsystem reset (CPU2. $\overline{SYSRS}$) resets only CPU2, the peripherals, and the clock gating and LPM configuration. CPU2 subsystem reset does not hold CPU2 in reset. CPU3 subsystem reset (CPU3. $\overline{SYSRS}$) resets only CPU3, the peripherals, and the clock gating and LPM configuration. CPU1 subsystem reset (CPU1. $\overline{SYSRS}$) resets CPU1, the peripherals, many system control registers (including the clock gating and LPM configuration and the peripheral CPU ownership), and all I/O pin configurations. CPU1. $\overline{SYSRS}$ also produces a CPU2. $\overline{SYSRS}$ and CPU3. $\overline{SYSRS}$ (CCS Gel file can have code to release CPU2 and CPU3 out of reset on CPU1 debug reset).

Figure 2-2 explains how the all CPU $\overline{SYSRS}$ and Software Reset signals are connected to cause particular peripheral to reset in the device.

Neither $\overline{SYSRS}$ resets the debug module, the device capability registers, the clock source and PLL configurations, the missing clock detection state, the PIPE vector fetch error handler address, the NMI flags, the analog trims, or anything reset only by a POR (see Section 2.3.4).

Figure 2-2. Software and SYSRSn Connectivity Diagram for Peripheral Reset

Note

Since the reset signals are active low any input to the AND gate when active (low) outputs the peripheral reset signal to be active (low).

2.3.6 Watchdog Reset ($\overline{WDRS}$)

Each CPU has a watchdog timer that can optionally trigger a reset that lasts for 512 INTOSC1 cycles. CPU1 watchdog reset (CPU1. $\overline{WDRS}$) produces an $\overline{XRS}$. CPU2 watchdog reset (CPU2. $\overline{WDRS}$) produces a CPU2. $\overline{SYSRS}$ and similarly CPU3 watchdog reset (CPU3. $\overline{WDRS}$) produces a CPU3. $\overline{SYSRS}$.

After a watchdog reset, the WDRSn bit in the RESC register is set. Software can read this bit to know the cause of reset and clear the status by writing a 1 into the corresponding bit in the RESCCLR register.

2.3.7 ESM NMI Watchdog Reset ($\overline{NMIWDRS}$)

Each ESM CPU module in ESM Subsystem (ESM-SS) has a watchdog timer that triggers a reset if the CPU does not respond to an error within a user-specified amount of time. ESM CPU1 NMI watchdog reset (ESM CPU1. $\overline{NMIWDRS}$) produces an $\overline{XRS}$. ESM CPU2 NMI watchdog reset (CPU2. $\overline{NMIWDRS}$) produces a CPU2. $\overline{SYSRS}$ and ESM CPU3 NMI watchdog reset (CPU3. $\overline{NMIWDRS}$) produces a CPU3. $\overline{SYSRS}$.

After an NMI watchdog reset, the NMIWDRSn bit in the RESC register is set.

2.3.8 EtherCAT SubordinateDevice Controller (ESC) Module Reset Output

The EtherCAT SubordinateDevice Controller (ESC) module can drive the $\overline{XRS}$ pin low whenever the ESC module receives a reset. This is done by setting the DEVICE_RESET_EN bit to 1 in the ESCSS_RESET_DEST_CONFIG register of the ESC module (EtherCAT subsystem). By default, this is not enabled. Since this toggles the $\overline{XRS}$ pin, all effects of an external $\overline{XRS}$ reset take effect.

After an ECAT_RESET_OUT reset, the ECAT_RESET_OUT bit in the RESC register is set. Software can read this bit to know the cause of reset and clear the status by writing a 1 into the corresponding bit in the RESCCLR register.

2.4 Interrupts

This device supports (4) types of interrupts: RESET, Non-Maskable INT, Real-time INT, and INT (including Supervisor INT). Refer to the [C29x CPU Reference Guide](#) for information on the C29x CPU Interrupts Architecture including types of interrupts, interrupt functionality, and safety and security.

2.4.1 External Interrupts (XINT)

Each CPU has an independent external interrupt (XINT) configuration. [Figure 2-3](#) shows how the external interrupt is connected to each CPU's PIPE.

Figure 2-3. External Interrupt Diagram

2.5 Safety Features

This section gives details on features that monitor device operation during run-time to detect any error in operation.

2.5.1 Write Protection on Registers

2.5.1.1 LOCK Protection on System Configuration Registers

Several system configuration registers are protected from spurious CPU writes by “LOCK” registers. Once these associated LOCK register bits are set, the respective locked registers can no longer be modified by software. See the register descriptions for details.

2.5.1.2 Commit Protection for Registers

Some lock registers also have commit feature which allows registers to be permanently locked until reset occurs. When commit is enabled then modifying lock register is not allowed until reset.

This adds extra protection against unintentional modification of locked registers.

2.5.1.3 EALLOW Protection

EALLOW protection mechanism is not applicable for this device.

2.5.2 PIPE Vector Address Validity Check

PIPE Vector tables are protected by ECC safety mechanism.

2.5.3 NMIWDs

Each ESM CPU instance has user-programmable NMIWD period registers, in which users can set a limit on how much time to allocate for the device to acknowledge the NMI. If the NMI is not acknowledged, the NMI causes a device reset.

2.5.4 System Control Registers Parity Protection

Critical System Control Register are parity protected. The registers that are covered by parity protection have “PARITY” mentioned in the respective “Protection” column in register descriptions table. There is also a provision to test the parity protection feature by enabling parity test using the DEV_CFG_REGS.PARITY_TEST, CPU_PER_CFG_REGS.PARITY_TEST_ALT1 and CPU_SYS_REGS.PARITY_TEST_ALT2 register.

If parity error is detected, ESM is notified and appropriate action is taken based on user configurations. Refer to ESM Chapter for more details.

2.5.5 ECC Enabled RAMs, Shared RAMs Protection

Each CPU subsystem has different RAM blocks. All the RAM blocks are ECC-enabled. All errors go to ESM and all single-bit ECC RAM errors are auto-corrected by ECC logic inside CPU. Also, an interrupt is generated to the corresponding CPU using ErrorAggregator and ESM. Single-bit errors are not corrected inside the RAM blocks; hence, RAM blocks still have the incorrect data (single-bit error). User software needs to write back the correct data.

All uncorrectable double-bit errors end up triggering an NMI to the corresponding CPUs using ErrorAggregator and ESM.

2.5.6 ECC Enabled Flash Memory

Flash single-bit errors are corrected automatically by ECC logic inside CPU, but the Flash single-bit errors are not corrected in Flash memory. Flash memory still contains wrong data until another erase/program operation happens to correct the Flash contents. Irrespective of whether the error interrupt is enabled or disabled, single-bit errors are always corrected. When the interrupt is disabled, users can check the single-bit error flag for any single-bit error occurrences.

Flash uncorrectable errors end up triggering an NMI to the respective CPU using ErrorAggregator and ESM.

2.5.7 ERRORSTS Pin

ERRORSTS signal is driven from Error Signaling Module (ESM). The ERRORSTS signal is 'always output' on a selected GPIO pin and remains high until an error is detected inside the chip. On an error, the ERRORSTS pin goes low (default polarity) until the corresponding internal error status flag for that error source is cleared.

The ERRORSTS pin is tri-stated until the chip power rails ramp up to the lower operational limit. As the ERRORSTS pin is an active-low pin (default polarity), users who care about the state of this pin during power-up can connect an external pull-down on this pin. Polarity of ERRORSTS pin is configurable (default setting is active-low polarity).

2.6 Clocking

This section explains the clock sources and clock domains on this device, and how to configure them for application use. Figure 2-4 provides an overview of the device clocking system.

Figure 2-4. Clocking System

2.6.1 Clock Sources

The needs of the application are what ultimately determine the clock configuration. Specific concerns such as application performance, power consumption, total system cost, and EMC are beyond the scope of this document, but consider the following questions:

1. What is the desired CPU frequency?
2. Are there any additional communication protocols or peripherals required ?
3. What types of external oscillators or clock sources are available?

If required, an external clock source with a precise frequency must be used as a reference clock. Otherwise, use only INTOSC2 and avoid the need for more external components.

All of the clocks in the device are derived from one of four clock sources.

2.6.1.1 Primary Internal Oscillator (INTOSC2)

At power-up, the device is clocked from an on-chip 10MHz oscillator (INTOSC2). INTOSC2 is the primary internal clock source and is the default system clock at reset. INTOSC2 is used to run the boot ROM and can be used as the system clock source for the application.

Note

INTOSC2 frequency tolerance is too loose to meet the timing requirements for some communication peripherals, so an external clock must be used to support those features.

2.6.1.2 Backup Internal Oscillator (INTOSC1)

The device also includes a redundant on-chip 10MHz oscillator (INTOSC1). INTOSC1 is a backup clock source that normally only clocks the watchdog timers and missing clock detection circuit (MCD). If MCD is enabled and a missing system clock is detected, the system PLL is bypassed and all system clocks are connected to INTOSC1 automatically. INTOSC1 can also be manually selected as the system and auxiliary clock source for debug purposes.

2.6.1.3 External Oscillator (XTAL)

The dedicated X1 and X2 pins support an external clock source (XTAL), which can be used as the main system. Frequency limits and timing requirements can be found in the device data sheet. Three types of external clock sources are supported:

- A single-ended 3.3V external clock. The clock signal must be connected to X1 while X2 is left unconnected, as shown in [Figure 2-5](#).

Figure 2-5. Single-ended 3.3V External Clock

- An external crystal. The crystal must be connected across X1 and X2 with the load capacitors connected to VSSOSC as shown in [Figure 2-6](#).

Figure 2-6. External Crystal

- An external resonator. The resonator must be connected across X1 and X2 with the ground connected to VSSOSC as shown in [Figure 2-7](#).

Figure 2-7. External Resonator

2.6.1.4 Auxiliary Clock Input (AUXCLKIN)

An additional external clock source is supported on GPIO133 (AUXCLKIN). This must be a single-ended 3.3V external clock that can be used as the clock source for MCAN bit clock. Frequency limits and timing requirements can be found in the device data sheet. The external clock must be connected directly to the GPIO133 pin, as shown in [Figure 2-8](#).

Figure 2-8. Auxiliary Clock Input (AUXCLKIN)

2.6.2 Derived Clocks

The clock sources discussed in the previous section can be multiplied (using PLL) and divided down to produce the desired clock frequencies for the application. This process produces a set of derived clocks, which are described in this section.

2.6.2.1 Oscillator Clock (OSCCLK)

One of INTOSC2, XTAL, or INTOSC1 must be chosen to be the controller reference clock (OSCCLK) for the CPU and most of the peripherals. OSCCLK can be used directly or applied through the system PLL to reach a higher frequency. At reset, OSCCLK is the default system clock and is connected to INTOSC2.

2.6.2.2 System PLL Output Clock (PLLRAWCLK)

The system PLL allows the device to run at the maximum rated operating frequency, and in most applications generates the main system clock. This PLL uses OSCCLK as a reference, and features a fractional multiplier and slip detection. For configuration instructions, see [Section 2.6.7](#).

2.6.3 Device Clock Domains

The device clock domains are applied to the clock inputs of the various modules in the device. The device clock domains are connected to the derived clocks, either directly or through an additional divider.

2.6.3.1 System Clock (PLLSYSCLK)

The system control registers, RAMs, IPC module, GPIO qualification, SSU, LCM, Flash read interfaces, FLC1/2, all SRAMs, XBAR, ESM, Peripheral Bridges, RTDMA1/2 and PIPE modules have a clock domain (PLLSYSCLK). Despite the name, PLLSYSCLK can be connected to the system PLL (PLLRAWCLK) or to OSCCLK. The chosen clock source is run through a frequency divider, which is configured using the SYSCLKDIVSEL register.

Note

The **minimum** clock divider should be SYSCLKDIVSEL.PLLSYSCLKDIV = 1. See *SPRZ569 (F29H85x, F29P58x, and F29P32x Real-Time MCUs Silicon Errata)* under the System advisory for details.

2.6.3.2 CPU Clock (CPUCLK)

Each CPU has a clock (CPU1.CPUCLK, CPU2.CPUCLK and CPU3.CPUCLK) that is used to clock the CPU, and the coprocessors. This clock is identical to PLLSYSCLK, but is gated when the CPU enters STANDBY mode. CPUCLK provides a clock to individual CPU timers (CPUTIMERx) and DLT.

2.6.3.3 Peripheral Clock (PERx.SYSCLK)

This clock is identical to PLLSYSCLK, but is gated when the CPU selected by CPUSEL enters STANDBY mode based on individual STANDBYEN bit in respective peripheral system configuration register (PERxSYSCONFIG).

Each peripheral has a CPU selection logic to select either CPU1, CPU2, or CPU3 that is done by using the CPUSEL register. The CPU selection logic is only for clock gating purposes, since there is no CPU to peripheral allocation and any CPU can access and configure any peripheral provided the respective CPU has access to the peripheral. Each peripheral clock also has an independent clock gating that is controlled by the CPU PCLKCRx and STANDBYEN registers.

By default, the ePWM, EMIF, and LIN clocks each have an additional /2 divider. At slower CPU frequencies, these dividers can be disabled using the PERCLKDIVSEL register.

Note

The application needs to wait for 10 SYSCLK cycles after enabling the clock to the peripherals, when using PCLKCRx.

2.6.3.4 MCAN Bit Clock

The required frequency tolerance for the MCAN bit clock depends on the bit timing setup and network configuration, and can be as tight as 0.1%. Since the main system clock (in the form of PERx.SYSCLK) can not be precise enough, the bit clock can also be connected to PLLCLK or AUXCLKIN using the CLKSRCCTL2 register. There is an independent selection for each MCAN bit clock source.

2.6.3.5 CPU Timer2 Clock (TIMER2CLK)

CPU timers 0 and 1 are connected to PLLSYSCLK. Timer 2 is connected to PLLSYSCLK by default, but can also be connected to INTOSC1, INTOSC2, XTAL, FLC1/2 PUMPOSC or CRUDEOSC using the TMR2CLKCTL register. This register also provides a separate prescale divider for timer 2. If a source other than PLLSYSCLK is used, the frequency must be at least twice the source frequency to make sure of correct sampling. Each CPU has independent CPU timers and TMR2CLKCTL register.

The main reason to use a non-SYSCLK source is for internal frequency measurement. In most applications, timer 2 runs off of the SYSCLK.

2.6.4 External Clock Output (XCLKOUT)

To observe a clock directly for debug and testing purposes, the external clock output (XCLKOUT) supports this by connecting a clock to external pins, GPIO73 and GPIO219. The available clock sources are PLLSYSCLK, PLLRAWCLK, PLLCLK, CPUx.CLOCK, XTAL, INTOSC1, and INTOSC2.

To use XCLKOUT, first select the clock source using the CLKSRCCTL3 register. Next, select the desired output divider using the XCLKOUTDIVSEL register. Finally, connect either GPIO73 or GPIO219 to mux channel 3 using the GPIO configuration registers.

2.6.5 Clock Connectivity

[Table 2-2](#) provides details on the clock connections of every module present in the device.

Table 2-2. Clock Connections Sorted by Clock Domain

Clock Domain	CPU1 Subsystem	CPU2 Subsystem	CPU3 Subsystem	Shared Modules
CPUx.CPUCLK	CPU1	CPU2	CPU3	
PLLSYSCLK				PIPEx GPIO Input Sync and Qual IPC XBARs EMIF1 AnalogSubsys SSU System Control Registers HRCAL RTDMAx ESM Peripheral Bridges LCM FR1x, FLC1/2 All SRAMs ERADx XINT HRPWM DLT CPUTimers

Table 2-2. Clock Connections Sorted by Clock Domain (continued)

Clock Domain	CPU1 Subsystem	CPU2 Subsystem	CPU3 Subsystem	Shared Modules
PERx.SYSCLK				ADC CMPSS DAC ePWM eCAP eQEP I2C SDFM FSI PMBUS CLB SPI LIN UART SENT WADI EPG

Table 2-2. Clock Connections Sorted by Clock Domain (continued)

Clock Domain	CPU1 Subsystem	CPU2 Subsystem	CPU3 Subsystem	Shared Modules
MCAN Bit Clock				MCAN (CAN-FD)
WDCLK (INTOSC1)	CPU1.Watchdog	CPU2.Watchdog	CPU3.Watchdog	

2.6.6 Using an External Crystal or Resonator

The X1 and X2 pins double as GPIO221 and GPIO220. At power-up, these pins are in GPIO mode and the on-chip crystal oscillator is powered off. The following procedure can be used to switch the pins to X1 and X2 mode and enable the oscillator:

1. Clear the XTALCR.OSCOFF bit.
2. Wait for the crystal to power up. The typical wait time is 1ms, but this depends on the crystal that is being used.
3. Select XTAL as the OSCCLK source by writing a 1 to CLKSRCCTL1.OSCCLKSRCSEL.
4. Check the MCLKSTS bit in the MCDCCR register. If the bit is set, the oscillator has not finished powering up, and more time is required:
 - a. Clear the missing clock status by writing a 1 to MCDCCR.MCLKCLR.
 - b. Do not reset the device. Doing so powers down the oscillator, which requires the procedure to be restarted from step 1.
 - c. If the oscillator has not finished powering up in 10 milliseconds, there is a real clock failure.
5. If MCDCCR.MCLKSTS is clear, the oscillator startup is a success. The system clock is now derived from XTAL.
6. Verify the XTAL (X1) clock frequency accuracy using the Dual Clock Comparator (DCC) module.

2.6.6.1 X1/X2 Precondition Circuit

The GPIO220/221 alternate functionality on X1/X2 can be used to speed up the start-up time of the crystal by as much as 30% if needed. This functionality is achieved by preconditioning the load capacitors CL1 and CL2 to a known state before the XTAL is turned on.

The steps below outline the procedure to precondition X1/X2 before turning on the XTAL:

1. DevCfgRegs.XTALCR2.bit.XIF = 1; // Precondition X1 to High
2. DevCfgRegs.XTALCR2.bit.XOF = 1; // Precondition X2 to High
3. DevCfgRegs.XTALCR2.bit.FEN = 1; // Enable X1/X2 Precondition
4. DEVICE_DELAY_US(1);
5. DevCfgRegs.XTALCR.bit.OSCOFF = 0; // Removes Precondition and Turns on the XTAL
6. DevCfgRegs.XTALCR2.bit.FEN = 0; // Disables X1/X2 Precondition

2.6.7 PLL

The PLL is responsible for synthesizing an output frequency from the input clock (from the oscillator). [Figure 2-9](#) shows a simple block diagram of the PLL. The PLL divides the reference input for a lower frequency input into the PLL by (REFDIV + 1). Then multiplies this internal frequency by IMULT to get the VCO output clock. The PLL output is divided by (ODIV + 1) to generate PLLRAWCLK that is further divided by SYSCLKDIVSEL.PLLSYSCLKDIV to generate PLLSYSCLK.

There is PLL also called as SYSPLL and the equations shown in [Figure 2-9](#) can be used to configure the respective PLL.

- IMULT is the integer value of the multiplier
- REFDIV is the reference divider for the OSCCLK
- ODIV is the output divider of the PLLRAWCLK
- PLLSYSCLKDIV is the system clock divider

For the permissible values of the multipliers and dividers, see the documentation for the respective registers.

Many combinations of multiplier and divider can produce the same output frequency. However, the product of the reference clock frequency and the multiplier (known as the VCO frequency) must be in the range specified in the data sheet.

Note

The system clock frequency (PLLSYSCLK) cannot exceed the limit specified in the data sheet. This limit does not allow for oscillator tolerance.

The clock source and PLL configuration can only be done by CPU1 and can be read by other CPUs.

Figure 2-9. PLL

2.6.7.1 System Clock Setup

Once the application requirements are understood, a specific clock configuration can be determined. The default configuration is for INTOSC2 to be used as the system clock (PLLSYSCLK) with a divider of 1. The following procedure can be used to set up the desired application configuration:

Refer to your device SysCtl_setClock() function inside the [F29x Software Development Kit \(F29-SDK\)](#) installation for an example.

Recommended sequence to set up the system PLL:

1. Bypass the PLL by clearing SYSPLLCTL1[PLLCLKEN] and wait for at least 120 CPU clock cycles by adding 120 NOP instructions.
2. Power down the PLL by writing to SYSPLLCTL1.PLEN = 0 and wait for at least 60 CPU clock cycles by adding 60 NOP instructions.
3. Select the reference clock source (OSCCLK) by writing to CLKSRCCTL1.OSCCLKSRCSEL and wait for at least 300 CPU clock cycles by adding 300 NOP instructions.
4. Set the system clock divider to /1 to make sure of the fastest PLL configuration by clearing SYSCLKDIVSEL[PLLSYSCLKDIV].
5. Set the IMULT, REFDIV, and ODIV simultaneously by writing 32-bit value in SYSPLLMULT at once. This automatically enables the PLL. Make sure the settings for multiplier and dividers do not violate the frequency specifications as defined in the data sheet.
6. Wait for PLL to lock by polling for lock status bit to go high, that is, SYSPLLSTS.LOCKS = 1
7. Configure DCC with reference clock as OSCCLK and clock under measurement as PLLRAWCLK, and verify the frequency of the PLL. If the frequency is out of range, do not enable PLLRAWCLK as SYSCLK, stop here and troubleshoot. Refer to [Chapter 11](#) for more information on the configuration and usage.
8. If the PLLRAWCLK is within the valid range, then set the system clock divider one setting higher than the final desired value. For example DEV_CFG_REGS.SYSCLKDIVSEL.bit.PLLSYSCLKDIV = divsel + 1. This limits the current increase when switching to the PLL.
9. Switch to the PLL as the system clock by setting SYSPLLCTL1[PLLCLKEN] and wait for 200 PLLSYSCLK cycles for current to stabilize by adding 200 NOP instructions.
10. Change the system clock divider (PLLSYSCLKDIV) to the appropriate value.

Note

1. SYSPLL must be bypassed and powered down manually before changing the OSCCLK source.
2. At least 120 CPU clock cycles delay is needed after bypassing PLL, that is, SYSPLLCTL1.PLLCLKEN = 0.
3. At least 60 CPU clock cycles delay is needed after PLL is powered down, that is, SYSPLLCTL1.PLEN = 0.
4. At least 300 CPU clock cycles delay is needed after OSSCLK source is changed.
5. PLL SLIP bit is not supported. DCC can be used to check the validity of the PLL clock. This feature is included as part of SysCtl_setClock() function inside the [F29x Software Development Kit \(F29-SDK\)](#).

2.6.7.2 SYS PLL Bypass

If the application requires the PLL clock to be bypassed from the system, then the application needs to configure SYSPLLCTL1.PLLCLKEN = 0. It takes up to 120 CPU clock cycles before the bypass is effective. In the meantime, if PLLSYSCLKDIV is reduced to a lower value (for example, from /2 to /1 or /4 to /2), the device can be clocked above the maximum rated frequency and can lead to unpredictable device behavior. Hence, a delay of 120 CPU clock cycles is required after bypassing the PLL from the enable state, that is, going from PLLCLKEN = 1 to PLLCLKEN = 0.

2.6.8 Clock (OSCCLK) Failure Detection

To achieve safety diagnostic, Missing Clock Detection (MCD) can be used. [Table 2-3](#) lists the details.

Table 2-3. Clock Source (OSCCLK) Failure Detection

Clock Failure Detection Circuitry	Clocks Detected	Time for Detection (in Cycles)	Limitations
Missing Clock Detection (MCD)	INTOSC2, XTAL/X1	8192 INTOSC1 cycles	Cannot detect INTOSC1 clock failure.
Dual Clock Comparator (DCC)	INTOSC1, INTOSC2, XTAL/X1	Depends on the frequency of reference and monitored clocks	Software configuration is required for clock monitoring

2.6.8.1 Missing Clock Detection Logic

The missing clock detect (MCD) logic detects OSCCLK failure, using INTOSC1 as the reference clock source. This circuit only detects complete loss of OSCCLK and does not do any detection of frequency drift on the OSCCLK.

This circuit monitors the OSCCLK (primary clock) using the 10MHz clock provided by the INTOSC1 (secondary clock) as a backup clock. This circuit functions as:

1. The primary clock (OSCCLK) clock keeps ticking a 7-bit counter (named as MCDPCNT). This counter is asynchronously reset with XRSn.
2. The secondary clock (INTOSC1) clock keeps ticking a 13-bit counter (named as MCDSCNT). This counter is asynchronously reset with XRSn.
3. Each time MCDPCNT overflows, the MCDSCNT counter is reset. Thus, if OSCCLK is present or not slower than INTOSC1 by a factor of 64, MCDSCNT never overflows.
4. If OSCCLK stops for some reason or is slower than INTOSC1 by at least a factor of 64, the MCDSCNT overflows and a missing clock condition is detected on OSCCLK.
5. The above check is continuously active, unless the MCD is disabled using MCDPCR register (by making the MCLKOFF bit 1).
6. If the circuit ever detects a missing OSCCLK, the following occurs:
 - The MCLKSTS flag is set.
 - The MCDSCNT counter is frozen to prevent further missing clock detection.
 - The CLOCKFAIL signal goes high, which generates TRIP events to PWM modules and can be configured to trigger NMI in Error Signaling Module (ESM)
 - PLL is forcefully bypassed and OSCCLK source is switched to INTOSC1 (System Clock Frequency = INTOSC1 Frequency (10MHz)/SYSDIV). PLLMULT is zeroed out automatically in this case.
 - While the MCLKSTS bit is set, the OSCCLKSRCSEL bits have no effect and OSCCLK is forcefully connected to INTOSC1.
 - PLLRAWCLK going to the system is switched to INTOSC1 automatically.
7. If the MCLKCLR bit is written (this is a W = 1 bit), MCLKSTS bit is cleared and OSCCLK source is decided by the OSCCLKSRCSEL bits. Writing to MCLKCLR also clears the MCDPCNT and MCDSCNT counters to allow the circuit re-evaluate missing clock detection. If the user wants to lock the PLL after missing clock detection, switch the clock source to INTOSC1 (using OSCCLKSRCSEL register), do a MCLKCLR, and relock the PLL.
8. The MCD is enabled at power up.

[Figure 2-10](#) shows the missing clock logic functional flow.

Figure 2-10. Missing Clock Detection Logic

Note

On a complete clock failure when OSCCLK is dead, the operation can take a maximum time of 8192 INTOSC1 cycles (that is, 0.8192ms) before the CLOCKFAIL signal goes high, after which:

- NMI is generated by enabling the CLOCKFAIL signal event configurations in ESM
- OSCCLK is switched to INTOSC1
- PWM Trip happens

2.6.8.2 Dual Clock Comparator (DCC)

DCC can be used for clock quality check as well as clock loss detection. Depending upon the counter settings in DCC, the desired goal can be achieved. In systems where DCC error is indicative of critical failure needing CPU intervention or reset, the DCC error is routed to NMI using ESM. Refer to [Chapter 11](#) for more details on the configuration.

2.7 Bus Architecture

This section covers the details about bus architecture.

2.7.1 Safe Interconnect

Safe interconnect mechanism detects any faults that occur in bus interconnect of C29x CPU and external memory or peripherals. Bus interconnect includes C29x CPU buses (control and data), address decodes, memory controllers and peripheral bridges.

Any data corruption in memory is detected and this is achieved by storing ECC along with data in memory.

To achieve safe interconnect there are checks that are done in the CPU and certain checks are implemented outside CPU. Forward path (CPU to Endpoint) checks are done at endpoint controller. Return path (Endpoint to CPU) checks are done by CPU. This provides end to end safing for the interconnect between initiators (CPU, RTDMA) to memory and peripherals.

In addition to the ECC checks every access placed on the bus has following checks associated :

1. Acknowledge (ACK) : Every access placed on the bus receives ACK from the endpoint (memory controller (in case of memory) or peripheral bridge (in case of peripherals)). This detects any address decode faults that is blocking the access propagation to endpoint.
2. Ready Timeout : Ready timeout checks if for any reason ready is indefinitely pulled low by endpoint due to a fault, timeout logic generates abort request to endpoint. Timeout value is user configurable in SICCONFIG register.

2.7.1.1 Safe Interconnect for Read Operation

CPU generates the ECC for the address and control information needed for the read access to endpoint. This ECC is propagated to memory controller and peripheral bridges along with address and control information.

ECC is for error detection only. When the fault is detected, the error is sent to ESM using the error aggregator and the CPU goes to a fault state. ESM needs to be configured to generate an NMI and to read from the address that was captured in the error aggregator. The user needs to write back the corrected data to fix the correctable error at the endpoint.

Safe interconnect mechanisms for read operations:

1. Base Address Check at the Endpoint - Checks for address decode faults
2. ECC Check at the Endpoint - On forward path (CPU to Endpoint) ECC check is performed on address and control information integrity. CPU performs ECC calculation on address and control information locally and send the same to endpoint for cross checking with the ECC calculated at endpoint locally
3. ECC Check at CPU - On return path (Endpoint to CPU) ECC along with Data is fed back to CPU. CPU performs ECC Check

Coverage of the following possible causes of errors are covered by the safe interconnect mechanisms employed:

1. Address decode fault, for example if the request is routed to the wrong memory due to fault in address decode interconnect logic
2. Address decode execution is correct but on the way to the endpoint if the address bits get flipped resulting in wrong address information sent to endpoint

2.7.1.2 Safe Interconnect for Write Operation

Checks performed are similar to read operation. In addition to address and control the write data is also checked for errors at endpoint in forward path. Write Data ECC generated on combination of address and data is also written along with data to endpoint without any modification if size of access is same as ECC granularity.

In case of endpoints like peripherals that do not support storing of ECC, the ECC is generated at the peripheral bridge so that transactions to and from peripheral bridge are covered.

2.7.2 Peripheral Access Configuration using FRAMESEL

The peripheral access from any initiators (CPUx and RTDMAx) is managed from FRAMES. All peripherals are mapped across 4 FRAMES such that every peripheral instance is accessed at one of the four memory-map addresses as shown in Table 2-4 and Table 2-5. The frame selection configuration mechanism allows non-conflicting Initiator to target accesses complete faster and without arbitration stalls. For example, EPWM1 peripheral instance configurations can be accessed from FRAME0 by CPU1 while EPWM2 peripheral instance configurations be accessed from FRAME1 by CPU3. SSU-APR configuration controls the access from CPU to each FRAME region.

Note

Not all peripherals access is managed from FRAMESEL, so check the respective chapter *Base Address* tables to see if the Structure is Frame Applicable or not.

Figure 2-11. Peripheral Access Configuration

Table 2-4. VBUS32 Frame Base Addresses

Peripheral Frame	Base Address
Peripheral Frame 0	7000_0000
Peripheral Frame 1	7040_0000
Peripheral Frame 2	7080_0000
Peripheral Frame 3	70C0_0000

Note

VBUS32 Frame Peripherals do not support x8 access. Any x8 Access to these peripherals gives a Bridge ACK error using Error Aggregator and ESM.

Table 2-5. VBUSP Frame Base Addresses

Peripheral Frame	Base Address
Peripheral Frame 0	6000_0000
Peripheral Frame 1	6040_0000
Peripheral Frame 2	6080_0000
Peripheral Frame 3	60C0_0000

Note

Check the data sheet Peripheral Registers Memory Map to see what peripherals are mapped to VBUS32 and VBUSP. All Base Address tables shown here are FRAME0 addresses. To find the respective FRAME addresses, add the FRAME0 offset to the respective FRAME base addresses.

2.7.3 Bus Arbitration

Access to same peripheral from multiple initiators is handled using the round-robin arbitration. Within round-robin arbitration the priority is given as below :

1. CPU1 Program access
2. CPU2 Program access
3. CPU1 Data accesses
4. CPU2 Data accesses
5. RTDMA1
6. RTDMA2
7. EtherCAT
8. HSM

The arbitration scheme makes sure that no initiator is stalled forever except when intentionally required by user during ATOMIC and burst operations. Back to back access or multiple simultaneous access from same initiator does not block other initiator from getting grant.

Access originating from same initiator is arbitrated using fixed priority as described below in case of CPU :

1. Write
2. Read Bus 1
3. Read Bus 2
4. Program Access

2.8 32-Bit CPU Timers 0/1/2

This section describes the three 32-bit CPU-Timers (TIMER0/1/2) shown in [Figure 2-12](#).

CPU-Timer2 is reserved for real-time operating system uses (for example, TI-RTOS), but if CPU-Timer2 is not used by real-time operating systems then, CPU-Timer2 can also be used for other applications. The CPU-Timer0 and CPU-Timer1 run off of PLLSYSCLK. The CPU-Timer2 normally runs off of PLLSYSCLK, but can also use INTOSC1, INTOSC2 or XTAL. The CPU-Timer interrupt signals (TINT0, TINT1, TINT2) are connected to the PIPE module. Refer to the *PIPE Channel Mapping* table in [Section 5.5.2.2](#) for more details.

Figure 2-12. CPU Timers

Note: The timer registers are connected to the memory bus of the C29x processor.

Note: The CPU Timers are synchronized to SYSCLKOUT.

The general operation of the CPU-Timer is as follows:

- The 32-bit counter register, TIMH:TIM, is loaded with the value in the period register PRDH:PRD.
- The counter decrements once every (TPR[TDDR.H:TDDR]) SYSCLKOUT cycles, where TDDR.H:TDDR is the timer divider.
- When the counter reaches 0, a timer interrupt output signal generates an interrupt pulse. The timer is reloaded *after* the prescaler counter also reaches 0.
- The number of cycles per interrupt = (PSC + 1) (PRD + 1) which can also be translated to the time period for every interrupt based on the input timer clock.

The registers listed in [Section 2.15](#) are used to configure the timers.

2.9 Watchdog Timers

The watchdog module generates an output pulse 512 watchdog-clocks (WDCLKs) wide whenever the 8-bit watchdog up counter has reached the maximum value. The watchdog clock source is INTOSC1. Software must periodically write a 0x55 + 0xAA sequence into the watchdog key register to reset the watchdog counter. The counter can also be disabled. Figure 2-13 shows the various functional blocks within the watchdog module.

Figure 2-13. CPU Watchdog Timer Module

2.9.1 Servicing the Watchdog Timer

The watchdog counter (WDCNTR) is reset when the proper sequence is written to the WDKEY register before the 8-bit watchdog counter overflows. The WDCNTR is reset-enabled when a value of 0x55 is written to the WDKEY. When the next value written to the WDKEY register is 0xAA, then the WDCNTR is reset. Any value written to the WDKEY other than 0x55 or 0xAA causes no action. Any sequence of 0x55 and 0xAA values can be written to the WDKEY without causing a system reset; only a write of 0x55 followed by a write of 0xAA to the WDKEY resets the WDCNTR.

Table 2-6. Example Watchdog Key Sequences

Step	Value Written to WDKEY	Result
1	0xAA	No action
2	0xAA	No action
3	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
4	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
5	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
6	0xAA	WDCNTR is reset.
7	0xAA	No action
8	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
9	0xAA	WDCNTR is reset.
10	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
11	0x32	Improper value written to WDKEY. No action, WDCNTR no longer enabled to be reset by next 0xAA.
12	0xAA	No action due to previous invalid value.
13	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
14	0xAA	WDCNTR is reset.

Step 3 in [Table 2-6](#) is the first action that enables the WDCNTR to be reset. The WDCNTR is not actually reset until step 6. Step 8 again re-enables the WDCNTR to be reset and step 9 resets the WDCNTR. Step 10 again re-enables the WDCNTR to be reset. Writing the wrong key value to the WDKEY in step 11 causes no action, however the WDCNTR is no longer enabled to be reset and the 0xAA in step 12 now has no effect.

If the watchdog is configured to reset the device, then a WDCNTR overflow or writing the incorrect value to the WDCR[WDCHK] bits resets the device and sets the watchdog flag (WDRSn) in the reset cause register (RESC). After a reset, the program can read the state of this flag to determine whether the reset was caused by the watchdog. After doing this, the program must clear WDRSn to allow subsequent watchdog resets to be detected. Watchdog resets are not prevented when the flag is set.

2.9.2 Minimum Window Check

To complement the timeout mechanism, the watchdog also contains an optional "windowing" feature that requires a minimum delay between counter resets. This can help protect against error conditions that bypass large parts of the normal program flow but still include watchdog handling.

To set the window minimum, write the desired minimum watchdog count to the WDWCR register. This value takes effect after the next WDKEY sequence. From then on, any attempt to service the watchdog when WDCNTR is less than WDWCR triggers a watchdog interrupt or reset. When WDCNTR is greater than or equal to WDWCR, the watchdog can be serviced normally.

At reset, the window minimum is zero, which disables the windowing feature.

2.9.3 Watchdog Reset or Watchdog Interrupt Mode

The watchdog can be configured in the SCSR register to either reset the device ($\overline{\text{WDRST}}$) or assert an interrupt ($\overline{\text{WDINT}}$), if the watchdog counter reaches the maximum value. The behavior of each condition is:

- **Reset mode:** If the watchdog is configured to reset the device, then the $\overline{\text{WDRST}}$ signal pulls the device reset ($\overline{\text{XRS}}$) pin low for 512 INTOSC1 cycles when the watchdog counter reaches the maximum value.
- **Interrupt mode:** When the watchdog counter expires, the watchdog asserts an interrupt by driving the $\overline{\text{WDINT}}$ signal low for 512 INTOSC1 cycles. $\overline{\text{WDINT}}$ is mapped to the PIPE module to assert appropriate CPU interrupt line as configured.

An error event input is also generated to ESM (for more details refer to ESM Inputs section in ESM Chapter) which can be configured to take actions as deemed necessary by system integrator.

To avoid unexpected behavior, software must not change the configuration of the watchdog while $\overline{\text{WDINT}}$ is active. For example, changing from interrupt mode to reset mode while $\overline{\text{WDINT}}$ is active immediately resets the device. Disabling the watchdog while $\overline{\text{WDINT}}$ is active causes a duplicate interrupt, if the watchdog is later re-enabled. If a debug reset is issued while $\overline{\text{WDINT}}$ is active, the reset cause register (RESC) shows a watchdog reset. The WDINTS bit in the SCSR register can be read to determine the current state of $\overline{\text{WDINT}}$.

2.9.4 Watchdog Operation in Low-Power Modes

In IDLE mode, the watchdog interrupt ($\overline{\text{WDINT}}$) signal can generate an interrupt to the CPU to take the CPU out of IDLE mode. User software must determine which peripheral caused the interrupt.

In STANDBY mode, clocks to the peripherals are turned off based on LPMCR, PCLKCRx and STANDBYEN registers. The CPU clock is gated when entering STANDBY mode based on LPMCR.LPM configuration but the watchdog remains functional since the module runs off the internal oscillator clock (INTOSC1). The $\overline{\text{WDINT}}$ signal is applied to the Low Power Modes (LPM) block, so that the LPM block can be used to wake the CPU from STANDBY low-power mode. This feature is enabled by setting LPMCR.WDINTE = 1. See [Section 2.10](#) for details. CPU can be brought out of IDLE or STANDBY mode using any of the enabled INT, RINT or NMI.

Note

If the watchdog interrupt is used to wake-up from an IDLE or STANDBY low-power mode condition, software must make sure that the $\overline{\text{WDINT}}$ signal goes back high before attempting to reenter the IDLE or STANDBY mode. The $\overline{\text{WDINT}}$ signal is held low for 512 INTOSC1 cycles when the watchdog interrupt is generated. The current state of $\overline{\text{WDINT}}$ can be determined by reading the watchdog interrupt status (WDINTS) bit in the SCSR register. WDINTS follows the state of $\overline{\text{WDINT}}$ by two SYSCLKOUT cycles.

2.9.5 Emulation Considerations

The watchdog module behaves as follows under various debug conditions:

CPU Suspended:	When the CPU is suspended, the watchdog clock (WDCLK) is suspended
Run-Free Mode:	When the CPU is placed in run-free mode, then the watchdog module resumes operation as normal.
Real-Time Single-Step Mode:	When the CPU is in real-time single-step mode, the watchdog clock (WDCLK) is suspended. The watchdog remains suspended even within real-time interrupts.
Real-Time Run-Free Mode:	When the CPU is in real-time run-free mode, the watchdog operates as normal.

2.10 Low-Power Modes

This device has two clock-gating, low-power modes. All low-power modes are entered by setting the LPMCR register and executing the IDLE instruction. More information about this instruction can be found in the [C29x CPU Reference Guide](#).

Low-power modes cannot be entered into while a Flash program or erase is ongoing. The application can verify the following before entering STANDBY:

1. Check the value of the GPIODAT register of the pin selected for STANDBY (GPIOLPMSEL0/1) prior to entering the low-power mode to make sure that the wake event has not already been asserted.
2. The LPMCR.QUALSTDBY register can be set to a value greater than the ratio of INTOSC1/PLLSYSCLK to make sure proper wake up.

2.10.1 IDLE

IDLE is a standard feature of the CPU. In this mode, the CPU is turned off while CPUx.CLOCK and all peripheral clocks are left running. IDLE can thus be used to conserve power while a CPU is waiting for peripheral events. When one CPU is in IDLE, there is no effect on the other CPU subsystem.

Any enabled interrupt wakes up the CPU from IDLE mode.

To enter IDLE mode, set LPMCR.LPM to 0x0 and execute the IDLE instruction.

2.10.2 STANDBY

STANDBY is a more aggressive low-power mode that gates both the CPU clock and any peripheral clocks derived from PLLSYSCLK (based on STANDBYEN setting). The watchdog however, is left active. Like IDLE, this mode affects only one CPU subsystem. The other CPU subsystem and all of the peripherals are unaffected. STANDBY is good for an application where the wake-up signal comes from an external system (or CPU subsystem) rather than a peripheral input.

An NMI (or optionally) any interrupt or a configured GPIO can wake the CPU from STANDBY mode. Each GPIO from GPIO0-63 can be configured to wake the CPU when the GPIO are driven active low. Additionally a CMPSS based wake up can be used for coming out of standby mode by configuring CMPSSLPMSEL register.

IPC interrupt 1 (flag 0), an NMI fired to the other CPU, or (optionally) any interrupt, wakes the CPU subsystem up from STANDBY mode. Any of GPIO0-63 can also be configured to wake up the subsystem when the GPIO is driven active low.

To enter STANDBY mode:

1. Set LPMCR.LPM to 0x1.
2. Enable the required interrupt in the PIPE
3. For watchdog interrupt wakeup, set LPMCR.WDINTE to 1 and configure the watchdog to generate interrupts.
4. For GPIO wakeup, set GPIOLPMSEL0 and GPIOLPMSEL1 to connect the chosen GPIOs to the LPM module, and set LPMCR.QUALSTDBY to select the number of OSCCLK cycles for input qualification.
5. Execute the IDLE instruction to enter STANDBY.

To wake up from Standby mode:

1. Configure the desired GPIO to trigger the wakeup.
2. Drive the selected GPIO signal low; the signal must remain low for the number of OSCCLK cycles specified in the QUALSTDBY bits in the LPMCR register. If the signal is sampled high during this period, the count restarts.

At the end of the qualification period, the PLL enables the CLKIN to the CPU and the associated wake up interrupt is latched in the PIPE module.

The CPU is now out of STANDBY mode and can resume normal execution.

2.11 Memory Subsystem (MEMSS)

This section discusses the memory subsystem of the device and how the buses, arbitration, and memory controllers are configured.

2.11.1 Introduction

The MEMSS, or Memory Subsystem, covers the memory architecture (RAM and ROM) used on the C29x platform. There are multiple initiators accessing the memories on the device like C29x CPUs, RTDMAs, HSM, and EtherCAT.

Each CPU has a 128-bit program bus, two 64-bit read buses, and a 64-bit write bus. Hence, there are separate [128-bit](#) and [64-bit](#) memory controllers that are optimized based on program or data access from specific CPU pairs.

Certain memories are optimized for zero wait state access from specific CPU pair (CPU1/2 or CPU1/3) and type of access (program or data) as described in [Table 2-7](#). Access from other initiators like RTDMA is pipelined but [burst mechanism](#) is added between RTDMA and MEMSS to improve throughput.

The MEMSS registers can be found in [Section 2.15](#).

Table 2-7. Naming Conventions

Name	Read Word Access	Zero Wait State Optimization
LPAX RAM	128-bit word	Program Access for CPU1 and CPU2
LDAX RAM	64-bit word	Data Access for CPU1 and CPU2
CPAX RAM	128-bit word	Program Access for CPU1 and CPU3
CDAx RAM	64-bit word	Data Access for CPU1 and CPU3

2.11.2 Features

The MEMSS implements the following features for memory:

- RAM:
 - RTDMA throughput optimization with local lookahead address generation
 - Common dataline buffer for each CPU (2x64-bit words)
 - Common program bridge for each CPU
 - ECC support with 32-bit granularity
 - Read-modify-write for write access smaller than ECC granularity
 - Posted write to minimize stalls on read-modify-write operation
 - Test mode to read/write ECC bits and error injection
- ROM:
 - ECC support with 64-bit granularity to reduce ECC bits overhead
 - One wait state program and data access
 - Prefetch with 256-bit wide memory
 - Dedicated local line buffer of 256 bits
- To reduce ECC bit overhead, there are no separate address ECC bits; ECC is generated by combining data and address

2.11.3 Configuration Bits

Each memory block has the following configuration bits:

- Test mode to read ECC bits and error injection (TESTMODE)
- Memory initialization trigger bit (MEMINIT)

These bits can be configured by CPU1 LINK0, LINK1, or LINK2. Debug accesses are only allowed if Zone 0 or Zone 1 are enabled for full-debug by all CPUs.

2.11.3.1 Memory Initialization

Memory initialization is initiated by writing to a software-programmable bit. Each memory has independent memory initialization control. Accesses are stalled for the memory being initialized until the initialization is complete. MEMINIT can be set only from CPU1 LINK0, LINK1, or LINK2.

2.11.4 RAM

This section details the architecture and configuration of the MEMSS for RAM.

2.11.4.1 MEMSS Architecture

Table 2-8 shows the different wait states for accessing different memory sections, depending on the initiator that is accessing the memory.

Note

In Table 2-8, nWS indicates a wait state of n cycles.

Table 2-8. Memory Configuration

RAM Section	Interleaved	CPU1	CPU2	CPU3	HSM	RTDMA1	RTDMA2
LPAX RAM	Yes	0WS program 1WS data	0WS program 1WS data	3WS data		1WS	1WS
LDAX RAM	Yes	1WS program 0WS data	1WS program 0WS data	3WS data	2WS	1WS	1WS
M0 RAM	Yes	0WS data	0WS data (read-only)	3WS data (read-only)			
CPAX RAM	Yes	0WS program 1WS data	3WS data	0WS program 1WS data		1WS	1WS
CDAx RAM	Yes	1WS program 0WS data	3WS data	1WS program 0WS data		1WS	1WS
CPU1 ROM	Yes	1WS program 1WS data					
CPU2 ROM	Yes		1WS program 1WS data				
CPU3 ROM	Yes			1WS program 1WS data			

Figure 2-14 shows the integration view of all the RAM and the respective accesses.

Figure 2-14. Integration View of All RAMs

2.11.4.2 RAM Memory Controller Overview

Each CPU has a dataline buffer in common for all RAMs. This buffer is only used for RAM accesses, and accesses to other regions of the memory map are not buffered or served from the dataline buffer. The Flash read interface and ROM controllers have dedicated line buffers local to the controller and are 256-bit wide memories.

Each CPU has a program bridge to interface 64-bit memories. This bridge is common for all 64-bit RAMs connected to a CPU and bridges the 128-bit bus of the CPU and the 64-bit buses of the LDx and CDx memory controller. Global bridge access allows data access to any RAM from any CPU which does not already have direct access, with a tradeoff of being three wait states to access the memory.

Memory controllers have a fast access port and slow access port. Fast access ports are zero wait state and limited, while slow access ports are one wait state and can have improved throughput if the initiator supports burst mode. Each CPU also has a debug access port, which are arbitrated externally. Only one port is routed to the memory controller. Debug accesses are connected to slow access ports.

Safe interconnect checks are done in initiators and memory controllers. Any errors resulting from HSM accesses are aggregated in the HSM-ESM, while others are aggregated in the ESM.

ECC granularity for RAM data is 32 bits. Write accesses of 8 or 16 bits require a read-modify-write operation. M0 memory is similar to LDx memory, and access permissions are determined by the SSU.

The LDx memories are accessible from the CPU and HSM and can be used as shared memories or dedicated memories. Freedom from interference is provided so the CPU does not get access to secure HSM data. The LDx memories have a multilayer protection:

- HSM controls shared memory access using independent USURP control for each LDx memory block (enables/blocks access completely)
- CPU enables the access to LDx memories using MPU present in HSM bridge. Only access to selected portion is allowed
- Two additional levels of protection that can be enabled with the SSU and other MPUs in the system

Read and write to the LDx memories is only allowed if both systems allow the access type, otherwise an access violation error is generated to the respective system.

2.11.4.3 Memory Controllers

2.11.4.3.1 128-Bit LPx and CPx Memory Controller

The 128-bit memory controller enables zero wait states on program accesses. This also allows data accesses, providing the ability to copy code, download code, and insert software breakpoints. Data accesses can be one or more wait states. Each logical block of the 128-bit memory has four memory banks. The data width of these RAMs is 39 bits (32-bit data and 7-bit ECC). The four banks are grouped together and the addresses are interleaved to form a 128-bit word. All data reads are treated as 64-bit reads, and 64-bit data is returned because the dataline buffer is 64-bit wide.

The 128-bit memory controllers have accesses from the following initiators:

- CPU1,2,3
- RTDMA1-2
- Debug

Figure 2-15 shows a generic view of the LPx and CPx (128-bit architecture) memory access from initiators to memory. There is separate memory controller for each block of memory, for example LPA0 and LPA1 have separate memory controllers.

Figure 2-15. Generic view of 128-Bit Memory

Figure 2-16 shows the generic view of the 128-bit memory controller which is an interface between initiators and individual memory blocks. The controller implementation remains same across LPx and CPx memories. Each instance of the controller is optimized for zero wait states from two specific CPUs (CPUa and CPUb). For example, LPx is optimized for CPU1 and CPU2 program access while CPx is optimized for CPU1 and CPU3 program access. For different memory, the controller functionality is the same but the CPUs that get connected as CPUa and CPUb are different.

CPU1 and CPU3 represents CPUa and CPUb for CPx memories while CPU1 and CPU2 represents CPUa and CPUb for LPx memories in the generic view of the [128-Bit Memory Controller](#).

Note

Program accesses from CPUs other than CPUa and CPUb are not supported. For example, LPx does not have CPU3 program access while CPx does not have program access from CPU2.

Figure 2-16. 128-Bit Memory Controller

The 128-bit controller has fast and slow access ports. Fast access ports have zero wait state program access from CPUa and CPUb. Slow access ports are intended for non-critical data access and have one wait state due to pipelining. Lookahead reads using the RTDMA burst signaling is supported on slow access ports.

Note

CPUa and CPUb use the respective clock domain when accessing memory.

The read-modify write operation happens in the background without stalling the CPU, using the write buffer close to the memory.

Data accesses from CPUs other than CPUa and CPUb are routed through [global access bridge](#). Debug access is routed through debug access bridge. The latency of these accesses is three wait states. Two wait states are introduced by the global access bridge for data access and debug access bridge for debug access with additional one wait state introduced by the slow access port of 128-bit memory controller.

Note

There is no restriction on using a portion of the program RAM as data memory, so long as the SSU setting allows for this. However, this is not recommended as arbitration affects CPU performance.

The following is the round-robin priority order:

1. CPUa Program Access
2. CPUb Program Access
3. CPUa Data Access
4. CPUb Data Access
5. RTDMA1
6. RTDMA2
7. Debug Access Bridge
8. Global Access Bridge

2.11.4.3.2 64-Bit LDx and CDx Memory Controller

The 64-bit LDx and CDx memory controller is similar to the 128-bit LPx and CPx memory controller, but differs in a few ways. The 64-bit memory controller has zero wait states on data access and one wait state on program access. Each block of 64-bit memory has two memory banks. The data width of these RAMs is 39 bits (32-bit data and 7-bit ECC). The two banks are grouped together and the addresses are interleaved to form a 64-bit word.

[Generic view of 64-Bit Memory](#) shows how the initiators access the LDx and CDx memories (with 64-bit architecture) through memory controller. Each memory block as shown in the view has separate memory controller, for example LDA0 and LDA1 have separate memory controller.

Figure 2-17. Generic view of 64-Bit Memory

Figure 2-18. 64-Bit Memory Controller

CPU1 and CPU3 represent CPUa and CPUb for CDx memories while CPU1 and CPU2 represent CPUa and CPUb for LDx memories in the generic view of the [64-Bit Memory Controller](#).

Fast access ports have zero wait states for program and data access from CPUa and CPUb. For example, LDx RAM has fast access port access for CPU1 and CPU2 program and data access while CDx RAM has fast port access for CPU1 and CPU3 program and data access.

Program access from other CPUs is not supported. For example, CPU3 does not have program access for LDx RAM. Fast access ports support 64-bit program access, and the program access bridge connects the 64-bit memory interface to the 128-bit memory bus of the CPU. The accesses between the program access bridge and the 64-bit memory controller are zero wait states, but the bridge initiates two accesses to form a 128-bit word. This is effectively one wait state for a 128-bit word with respect to CPU. The CPUa and CPUb data write access ports have one level of buffering, and the write buffer also handles read-modify-write operations.

Data access from other CPUs is supported by global bridge access as explained in detail in [Global Access Bridge](#) section. For example, CPU3 data access for LPx memories is through the global access bridge while CPU2 data access for CDx memories is through global access bridge.

The following is the round-robin priority order:

1. CPUa Program Access
2. CPUb Program Access
3. CPUa Data Access
4. CPUb Data Access
5. RTDMA1
6. RTDMA2
7. HSM
8. Debug Access Bridge
9. Global Access Bridge

Other details regarding the 64-bit memory controller are the same as the 128-bit memory controller, with the only difference being the width of the memory controller. Refer to [Section 2.11.4.3.1](#) for more information.

2.11.4.3.3 M0 Memory Controller

M0 memory is similar to LDAX memory, but M0 only has accesses from the CPUs. Below are some restrictions on M0. Refer to SSU Chapter for more details.

- No RTDMA access
- Only CPU1 has permission read/write
- Only read is supported from CPU2 and CPU3
- Fetch is not allowed

2.11.4.4 RTDMA Burst Support

RTDMA is connected through a slow access port as shown in [Figure 2-19](#), so all accesses are minimum one wait state. To improve throughput, RTDMA supports local address generation within the MEMSS memory controller. This enables performance close to zero wait states.

Local address generation within a burst is enabled by the following signals:

- First access of burst sequence (FIRST)
- Last access of burst sequence (LAST)
- Address Increment for next address (XCNT)
 - Next Address = Current Address + XCNT; this is for lookahead access generation

Figure 2-19. RTDMA Read

Without burst signaling, the address is latched first and then presented to memory. With burst, this happens only once for the first access, since the MEMSS memory controller does not use addresses generated by the RTDMA for subsequent accesses, as addresses is generated locally.

The LAST signal is an indication to stop the lookahead read. If the LAST signal is not generated, the RTDMA request going inactive is treated as a burst termination.

The RTDMA arbitration is locked when the FIRST access of a burst is granted, and the arbitration is released on the LAST access. Accesses with the FIRST and LAST signals asserted are treated as non-burst, and a lookahead read is not initiated nor is the arbitration locked. The arbitration lock is removed if the RTDMA channel is halted due to a CPU halt.

2.11.4.5 Atomic Memory Operations

The ATOMIC.M, or atomic, operation executes a protected sequence of memory operations while preventing other memory initiators from interrupting. This sequence can involve reading and updating shared variables in memory, where there is a need to protect these variables from updates by other initiators. The CPU atomic operation feature is typically used to implement a mutex or semaphore operation on shared data.

For true atomic CPU operations, the atomic operation must extend to memory accesses. The arbitration is locked to the CPU doing the atomic operations as soon as access is granted to the CPU. This can be a read or write operation. The lock is released when both signals transition low. From this point, other initiators can access the memory. This is visualized in [Figure 2-20](#).

Figure 2-20. Atomic Operations in the MEMSS

The CPU atomic operation extends to a maximum of 256 instruction packets. For atomic operations, reads are always directed to the memory controller to fetch the latest data from memory to make sure the latest data is being returned.

The arbitration lock is removed if the corresponding CPU enters a halt state. This prevents other initiators from being stalled forever and causing the CPU timeout checkers to generate a fault in the case where a CPU is halted. For this reason, atomic operations among initiators is not specified under debug scenarios. To maintain an atomic sequence during debug the DBGMC control must be used to mark the atomic sequence as non-halttable.

Read-modify-write and memory-to-memory data move CPU instruction types are treated as regular reads and writes by the MEMSS. To have these operations treated as a protected sequence, the instructions need to be explicitly included in an atomic section of the code.

More than one memory controller can be locked to a CPU if the atomic block of code accesses more than one memory block. The lock is released simultaneously for MEMSS memory controllers at the end of an atomic sequence. If there are back-to-back atomic blocks being executed on a CPU, the MEMSS memory controller can be locked to that CPU through all blocks of code.

If a CPU has both an atomic read and atomic write, the access arbitration follows the fixed priority scheme. If two or more CPUs have atomic accesses, the arbitration is locked to one CPU and moves round-robin among the

other CPUs. When some CPUs have non-atomic accesses, the accesses are serviced in between each access in the round-robin scheme. For example, if CPU1 has an atomic access, CPU2 has a non-atomic access, and CPU3 has an atomic access, and CPU1 is currently being serviced with an atomic lock, then one access for CPU2 is serviced followed by an atomic lock for CPU3.

2.11.4.6 RAM ECC

All RAMs have ECC protection with a 32-bit granularity. This means that every 32 bits has 7 bits of ECC. ECC for write data is generated in the CPU and written to memory directly. The read-modify-write operation is performed within the MEMSS memory controller for accesses that are less than 32 bits, and the ECC is generated locally for these write accesses.

Note

There is no separate address ECC. The ECC code generated is a combination of the address and data.

2.11.4.7 Read-Modify-Write Operations

Memory initiators are byte addressable and can generate write accesses that are 8/16/32/64 bits. A read-modify-write operation is performed locally in the MEMSS memory controller for 8 and 16-bit write accesses.

2.11.4.8 Dataline Buffer

[Figure 2-21](#) shows a high level view of the dataline buffer scheme. LB1 and LB2 are two data Line Buffers. The buffer is reset by the respective CPUx.SYSRSn reset.

Figure 2-21. Dataline Buffer

LB1 is loaded with data returned on data read bus 1, while LB2 is loaded with data from data read bus 2. The width of line buffer is 64 bits and has an associated valid bit (Vx) and address tag (ATAGx). ATAGx is a 64-bit aligned address of the data being held in the dataline buffer. The memory controller returns 64 bits of data regardless of the read access size. On every read access, the read address is compared with the ATAGx of LB1 and LB2. When the tag matches, data is returned from the corresponding dataline buffer. Read access to the memory controller is blocked at that time.

Initiators other than the CPU have access to RAM on the device. The dataline buffer is updated on CPU reads only, and the data in the buffer does not hold the latest data if another initiator updated the same address already. Write accesses from other initiators are tracked local to the dataline buffer, as shown by the "Write Access Tracker from Other Initiators" in [Figure 2-21](#). The dataline buffer is marked as invalid upon write access completion from another initiator if the address tag matched the write address. The CPU reads the old data until the time at which the buffer is marked as invalid using the Vx bit.

The CPU can issue a read and write to the same address simultaneously, in which case the dataline buffer detects this and invalidates the dataline buffer when there is an address tag match. An address tag match to a write address does not update the dataline buffer locally. For this, the write is performed to memory first then a read is initiated to fetch the latest data. This is shown by "CPU Write Access Tracker" in [Figure 2-21](#).

The ECC check is done within the CPU. When there is an uncorrectable ECC error detected, the CPU enters a fault state. Dataline buffers of a CPU are invalidated upon any CPU fault.

Dataline buffer needs to be disabled using MEM_DLB_CONFIG register before memory initialization or running test mode to invalidate last buffered data.

ECC Checks are also performed in the sync bridge as part of the safe interconnect and errors are sent to the HSM-ESM (Error Signaling Module).

2.11.4.10 Access Bridges

2.11.4.10.1 Debug Access Bridge

The debug access bridge arbitrates and connects one set of read and write ports from a CPU to the MEMSS memory controller using static select arbitration as described in [Section 2.11.6](#). This is common to the entire system. Arbitration and security access filtering can take up to two cycles, and debug accesses through this bridge are a two wait state minimum.

Figure 2-23. Debug Access Bridge

The initiator select connects one of the CPU buses to a common debug port, so the output buses cannot have accesses from more than one initiator at a given time. Debug read and write accesses identified as illegal are blocked in the debug access bridge.

Common debug access ports have a CPU-ID to indicate the origin of the current access. This ID can be used to implement access filtering, if needed. Following are the CPU-ID assignments:

- CPU1: 0001
- CPU2: 0010
- CPU3: 0011

The two types of memory regions have access filter handling :

1. Peripheral and uniquely memory-mapped memories
 - a. The SSU handles access filtering.
2. Tightly-coupled CPU peripherals (that is, PIPE, ERAD, and the CPU). These are mapped at some address respective to the CPU memory-map, and only the respective CPU has access to that memory (access checked using CPU-ID).
 - a. The SSU access filter always allows access to the ERAD region.

2.11.4.10.2 Global Access Bridge

The global access bridge arbitrates accesses in a round-robin priority. Data access to RAM is accessible from all CPUs, with 9 CPU ports on the RAM controller (two data read ports and one data write port for each CPU). Data accesses are optimized for two CPUs, connected to the MEMSS memory controller directly. Accesses from the remaining CPUs are arbitrated and merged into a generic CPU port with two data read and one data write port. These ports are connected to only one CPU at any given point in time. Figure 2-24 depicts how the LDAn memories are optimized for zero wait states by connecting CPU1 and CPU2 to the direct access port and CPU3 to the global bridge.

Figure 2-24. Global Access Bridge for LDAn RAMs

At any given time, accesses from one CPU are routed to the other side of the bridge. This global access bridge has only one set of output ports; hence, two different CPUs from bridge cannot access two memory instances concurrently. When a specific CPU is granted access, all active accesses from that CPU are placed into memory simultaneously, helping to support the throughput as shown in Figure 2-25.

Figure 2-25. Global Access Bridge Arbitration

The global access bridges available to each RAM are shown by Figure 2-14. The global access bridges support atomic operations and posted write with the write buffer. The posted write support is common for all CPUs.

2.11.4.10.3 Program Access Bridge

Figure 2-26 shows the program access bridge, which bridges the 128-bit bus of the CPU and the 64-bit bus of the LDx and CDx memories. The program access bridge is only active when the program access is issued to LDx and CDx memories. The bridge issues two 64-bit accesses in place of one 128-bit access from the CPU. Data is then locally buffered to accumulate 128-bits before returning to the CPU.

Program accesses to LPx and CPx memories bypass the program bridge and are transparent. If the address falls on the second half of the 128-bit word only one access is issued, with the lower 64 bits of the data word ignored by the CPU.

Note

Prefetch access is not supported for M0 RAM from any CPU.

Figure 2-26. Program Access Bridge

2.11.5 ROM

This section details the architecture and configuration of the MEMSS for ROM. Each CPU has dedicated ROM. Program and data accesses are supported and are one wait state. Multiple ROM banks are interleaved to form 256-bit words. ECC is implemented with a 64-bit granularity, which is the same as Flash. A prefetch buffer compensates for the one wait state latency. There is a local 256-bit dataline buffer that holds the last data read from ROM.

Figure 2-27. ROM Controller

The following is the round-robin priority order:

1. CPUa Access
2. Debug Access

2.11.5.1 ROM Dataline Buffer

The ROM memory controller has a 256-bit dataline buffer. The latest CPU data access from ROM is stored in the dataline buffer. ECC bits are stored with data. Program accesses from the CPU do not affect the dataline buffer. During a simultaneous data read access from bus 1 and bus 2, if the address of the accesses is within the 256-bit aligned address then only one access is issued to ROM. The second access is served from the same data. Debug read access is not buffered in the dataline buffer.

The dataline buffer is flushed when the CPU enters a fault state. The test mode does not affect the dataline buffer operation since ROM is read-only. Depending on the test mode setting, either data or ECC bits are returned.

2.11.5.2 ROM Prefetch

Upon the first program access, data is fetched from memory and presented to the CPU. On every access to ROM, 256 bits are fetched from the address that is aligned to the 256-bit boundary. The prefetch buffer can store up to two 256-bit words and stores both ECC and data. The ROM memory controller prefetches data from the next sequential 256-bit boundary-aligned address as long as there is an empty slot in the prefetch buffer. This is known as a prefetch access. Prefetch and program accesses are lower priority than data accesses as shown in [Arbitration](#) section.

This process does not start until ROM receives the first program access. After reset, the prefetch logic is idle until a program access with a discontinuity is received. This discontinuity is indicated by the CPU.

The prefetch buffer is flushed whenever a CPU program access with a discontinuity anywhere on the memory map occurs, not just when ROM is accessed.

2.11.6 Arbitration

The MEMSS uses a three-level arbitration scheme. The first level of arbitration is the fixed priority arbiter, which arbitrates accesses originating from within the same initiator. The following is the priority for the CPU accesses:

1. Write
2. Read Bus 1
3. Read Bus 2
4. Program Access (applies to ROM)
5. Prefetch Access (generated locally and applies to ROM)

Initiators other than the CPU have only one read and one write bus, arbitrated with the following priority:

1. Write
2. Read Bus

Figure 2-28. Three-Level Arbitration Scheme

The second and third level of arbitration controls the initiator selects. Initiator select 1 and 2 are controlled by independent round-robin pointers RR1 and RR2 respectively. RR1 arbitrates accesses connected to slow access ports. When access is granted by RR1, the access is pipelined and then passes to initiator select 2. Next, RR2 arbitrates accesses from initiator select 1 and fast access ports.

The following tables help to illustrate the round-robin arbitration using 64-bit memory controller as an example and same applies to 128-bit memory controller.

Table 2-9. Example 1

Cycle	CPUa	RTDMA1	RTDMA2	Round-Robin Pointer 2	Round-Robin Pointer 1	Access Granted at Initiator Select 1	Memory Access
1	CPUa Read Access 1	RTDMA1 Read Access 1	RTDMA2 Read Access 1	CPUa	RTDMA1		CPUa Read Access 1
2	CPUa Read Access 2	RTDMA1 Read Access 1	RTDMA2 Read Access 1	CPUa	RTDMA1	RTDMA1 Read Access 1	CPUa Read Access 2
3		RTDMA1 Read Access 1	RTDMA2 Read Access 1	Initiator Select 1	RTDMA1	RTDMA1 Read Access 1	RTDMA1 Read Access1
4			RTDMA2 Read Access 1	Initiator Select 1	RTDMA2		
5			RTDMA2 Read Access 1	Initiator Select 1	RTDMA2	RTDMA2 Read Access 1	RTDMA2 Read Access1

Table 2-9. Example 1 (continued)

Cycle	CPUa	RTDMA1	RTDMA2	Round-Robin Pointer 2	Round-Robin Pointer 1	Access Granted at Initiator Select 1	Memory Access
6				Initiator Select 1	RTDMA2		
7	CPUa Read Access 3			Initiator Select 1	RTDMA2		
8	CPUa Read Access 3			CPUa	RTDMA2		CPUa Read Access 3
9				CPUa	RTDMA2		

Table 2-10. Example 2

Cycle	CPUa	RTDMA1	RTDMA2	Round-Robin Pointer 2	Round-Robin Pointer 1	Access Granted at Initiator Select 1	Memory Access
1	CPUa Read Access 1	RTDMA1 Read Access 1	RTDMA2 Read Access 1	CPUa	RTDMA1		CPUa Read Access 1
2	CPUa Read Access 2	RTDMA1 Read Access 1	RTDMA2 Read Access 1	CPUa	RTDMA1	RTDMA1 Read Access 1	CPUa Read Access 2
3	CPUa Read Access 3	RTDMA1 Read Access 1	RTDMA2 Read Access 1	Initiator Select 1	RTDMA1	RTDMA1 Read Access 1	RTDMA1 Read Access 1
4	CPUa Read Access 3		RTDMA2 Read Access 1	CPUa	RTDMA2		CPUa Read Access 3
5	CPUa Read Access 4		RTDMA2 Read Access 1	CPUa	RTDMA2	RTDMA2 Read Access 1	CPUa Read Access 4
6			RTDMA2 Read Access 1	Initiator Select 1	RTDMA2		RTDMA2 Read Access 1
7				Initiator Select 1	RTDMA2		
8				Initiator Select 1	RTDMA2		
9				Initiator Select 1	RTDMA2		

The default initiator selects at reset is set such that the primary CPU has access to the memory (that is, the primary CPU has access to LPx, LDx, CDx, CPx, and M0 by default).

The round-robin pointer is changed when triggered by a pending request from an initiator other than the one currently granted access. The pointer is changed to the next initiator with priority, which takes 1 cycle. This occurs for each round-robin pointer, with greater weight given to initiators coming from fast access ports.

This two-level arbitration scheme makes sure that no initiator is stalled forever except for atomic and burst operations. Back-to-back accesses or multiple simultaneous accesses from an initiator does not block the other initiator from getting granted access. Essentially, when the round-robin pointer is set to an initiator, a pending request from any other initiator forces the round-robin pointer to switch, so there is fair arbitration without blocking an initiator.

For example, if CPUa and CPUb are initiating back-to-back read accesses the round-robin pointer switches between CPUa and CPUb every cycle so accesses from CPUa and CPUb are served alternatively one after the other.

Another example is if CPUa initiates four possible accesses (program read, data read 1, data read 2, and data write) and the RTDMA is initiating back-to-back read accesses at the same time. If the current pointer is set to CPUa, only the CPUa data write access gets granted before the pointer is switched to RTDMA to serve the read request. The pointer is then switched back to service CPUa program read, and at this time both the new RTDMA request as well as the CPUa data read 1 and 2 are pending. The pointer is switched back to CPUa to serve the data read 1 access and then CPUa data read 2 access.

2.11.7 Test Modes

Test modes can be used for implementing diagnostics tests on memory controllers. These modes enable error injection in data and ECC. The memory controller supports three modes of operation:

- Mode 0: Normal mode of operation
- Mode 1: Write to memory does not update the ECC, only data bits are updated (reading the ECC check is disabled)
- Mode 2: Reading an address returns ECC bits of the data at that address. Writing updates the ECC bits, while the data bits remain unchanged (reading the ECC check is disabled)

In mode 2, only 32-bit reads are supported. The ECC bits appear in byte 0 position of the read data.

The following is an example sequence to inject faults into RAM to implement diagnostics tests:

1. Write data to an address in mode 0 (both data and ECC get written to memory)
2. To induce errors on the data, set the mode to 1; to induce errors on ECC, set the mode to 2
3. Set the mode back to 0
4. Read the same address, with handling available if there is an error

ECC checks are performed in the CPU. CPU has built-in self-test controller and fault emulation to implement diagnostics. The MEMSS test mode is to implement diagnostic tests on ECC logic used for read-modify-write operations local to the memory controller.

Note

Test mode is not a global setting. Each memory controller has a separate TESTMODE control.

The test mode can be enabled by CPU1 code running from LINK0, LINK1, and LINK2. RAM test mode takes effect only for CPU1 accesses. Accesses from other initiators are serviced in the normal mode of operation, irrespective of the RAM test mode setting. Implementing ECC diagnostics for read-modify-write from CPU1 is sufficient since ECC checking logic is common for all initiators. A software handshake can be implemented in case RAM diagnostics are run on shared memory addresses.

Note

The dataline buffer is recommended to be disabled when using test modes to avoid RAM test data from getting buffered.

Real-time interrupts can still be enabled during diagnostics. In this scenario, an atomic sequence can be used to make sure the real-time interrupt is taken only after the dataline buffer is enabled and RAM is configured to mode 0.

2.11.8 Emulation Mode

Safe interconnect checks are disabled for debug accesses. Debug accesses that are less than 32 bits cause a read-modify-write operation. Any errors during this operation do not trigger an NMI, so as to avoid an NMIWD timeout while the CPU is halted. A status is set in the debug controller for CCS to read. An arbitration lock to a CPU is released if that CPU is halted. The RTDMA completes the burst if enabled before being halted.

Debug accesses are tracked as part of the dataline buffer and the buffer is flushed during debug writes.

2.12 System Control Register Configuration Restrictions

Memory-mapped registers in System Control operate on INTOSC1 clock domain, hence any CPU writes to these registers requires delay in between subsequent writes otherwise second write can be lost. The application needs to take this into consideration and check the **SYNCBUSY** and **SYNCBUSYWD** status registers after every write to the registers that are mentioned in [Table 2-11](#).

2.13 Device Initialization Software Sequence

It is important to understand both the boot and application startup flow, when developing embedded software design for the F29x device series.

Note

The following section references the [F29x-SDK](#) Driverlib functions which are used in all the software examples and static reference files provided.

2.13.1 Boot Start-Up Flow

Upon power-up, the CPU1 boot ROM sequence runs first. Based on the configured boot-mode pins, the associated bootloader executes and jumps to the C29x application entry point under Link2 execution. Full step-by-step detail is in the [BootROM TRM chapter](#) and HSM User Guide.

2.13.2 Application Start-Up Flow

In the SDK software examples, users will see two commonly used functions for system-level initialization:

- Device_init(): Initialize clocking, flash, interrupt, and watchdog configuration.
- Board_init(): Initialize individual peripheral configurations.

The following table summarizes the necessary steps for an application start-up, in order of execution.

Table 2-12. CPU Applicability Summary

Called From	Function	CPU1	CPU2	CPU3
Device_init()	Watchdog disable	Yes	Yes	Yes
	Note CPU1 WD resets the entire device. CPU2/3 WD resets only the core's own subsystem.			
	Clock initialization	Yes	N/A	N/A
	Flash wait-state initialization	Yes	N/A	N/A
	Peripheral clocks enable	Yes	N/A	N/A
	Interrupt module/vector initialization	Yes	Yes	Yes
Board_init()	Peripheral initialization	Yes	Yes	Yes
Main function - Multi-Core	Interrupt enable	Yes	Yes	Yes
	Reset vector & NMI vector initialization	N/A	Yes	Yes
	Note CPU1 has fixed vector values in hardware. CPU1 configures the values for CPU2 and CPU3 before releasing their reset.			
	Cross-core IPC sync	Yes	Yes	Yes

2.13.2.1 Device_init()

Part 1: Disable watchdog (Optional)

The first step in Device_init() disables the watchdog via SysCtl_disableWatchdog(). This is important because the BootROM has it enabled throughout its execution and the jump to application code, and the remainder of initialization must not risk interruption by an expiring timer.

This function occurs on all three CPUs, as there is a watchdog per CPU. A watchdog expiry on CPU1 resets the entire device; on CPU2 or CPU3, it resets only that CPU's own subsystem.

Part 2: Clock configuration (CPU1 only)

The CLOCK_init() function is called only in the CPU1-context build and configures the following system-level clocking:

- (Required) SysCtl_setClock(): configures the PLL/SYSCLK from the selected oscillator source.
- (Optional) Additional SysCtl_set<Peripheral>Clock() functions: configure peripheral clocking for EPWM, MCAN, etc., whose input clock source and divider configuration options are present in the device configuration registers (DEV_CFG_REGS).

Refer to the [Clocking TRM chapter](#) for complete details of the F29x clocking scheme and hardware capabilities.

Part 3: Flash wait-state configuration (CPU1 only)

Flash wait-state configuration runs after CLOCK_init() completes, because the wait-state value is only valid relative to the SYSCLK frequency actually in effect once the application executes.

Part 4: Peripheral clock enable

Device_init() enables peripheral clocks via one of two paths. By default, Device_enableAllPeripherals() unconditionally enables clocks for every peripheral instance on the device, whether the application uses them or not. If the SysCtl SysConfig module has enable_all_peripheral_clocks set to false, PERCLOCK_init() runs instead, enabling only the peripherals configured in the project.

Note: Enabling a peripheral's clock here does not assign CPU ownerships. This is done as part of Board_init() using the SysCtl_selectCPUForPeripheral() function.

Part 5: Interrupt controller and vector table initialization

Interrupt_initModule() clears and reinitializes the PIPE interrupt-controller memory, then assigns every interrupt's link owner and interrupt stack pointer to LINK2/STACK2. Interrupt_initVectorTable() loads a default interrupt handler into every vector slot and, on CPU1 only, programs the default NMI vector.

Note: CPU2 and CPU3 do not program this NMI vector themselves. Refer to the multi-core section for more information.

2.13.2.2 Board_init()

Note

The functions referenced in this section are present in the SysConfig generated board.c and board.h. Each function calls upon necessary DriverLib functions based on the project's configuration needs.

Board_init() configures the remaining peripherals at the device and peripheral level.

RTDMax, a bus initiator on this device, is configured in this step. Most notably, RTDMax_MPU_init() disables the RTDMax MPU by default, so DMA accesses go through.

The following are some of the functions used to configure the device:

1. ESMCPU_init() and ESMSYSTEM_init() configure the fault-detection hardware first, so that a fault triggered by any later step is captured rather than going undetected.
2. PinMux_init() and related functions such as GPIO_init() routes each configured peripheral's signal to its assigned pin, including analog and digital I/O pin properties.
3. PERCONFIG_init() assigns CPU and frame ownership for each peripheral.
4. SYSTCL_init() configures CPU lockstep/splitlock mode, reset behavior on critical ESM and NMI-watchdog events, low-power mode wake-up, and clock-fail/PLL-slip error signaling.
5. MEMCFG_init() sets bus arbitration priority and access protection for shared memory.
6. INPUTXBAR_init() (CPU1 only) routes external and peripheral signals into buses that other peripherals use as trigger sources.
7. INTERRUPT_init() registers and enables the application's interrupt sources. This is intentionally sequenced after peripheral, pin, and clock configuration, so that an interrupt cannot fire against hardware that is not yet in a defined state.

2.13.2.3 Main Function

The main() function performs a few additional steps after Device_init() and Board_init(), primarily enabling interrupts globally, and, on CPU1, releasing CPU2 and CPU3..

2.13.2.3.1 Interrupt Enable

While Device_init() sets up the PIPE modules associated with each CPU and Board_init() sets up interrupt handlers and enables interrupts at the peripheral level, the user must enable interrupts globally in the main function.

Interrupt_enableGlobal() writes the PIPE global enable register to allow both INT and RTINT interrupt types to be forwarded out of the PIPE controller. The ENINT CPU instruction enables interrupt propagation to the core itself. Both must be called before any registered interrupt can execute.

2.13.2.3.2 Multi-Core Execution

Each core runs Device_init() and Board_init() independently, except for CLOCK_init(), which runs only on CPU1. Once CPU1 initialization finishes, CPU2 and CPU3 can be released one at a time. CPU1 boots each core using four calls per core: (CPU2 or CPU3):

1. SSU_configBootAddress() sets the default reset address where the core starts executing from.
2. SSU_configNmiAddress() sets the default NMI vector where the core will branch to during a system-level error.
3. SSU_controlCPUReset() deactivates the core's reset line.
4. SysCtl_isCPUxReset() is polled until the core reads out of reset, before CPU1 can continue releasing other cores and CPU1 main application code.

After releasing both cores, CPU1 enables its own interrupts in main(), then synchronizes with the other cores in the system via IPC_sync().

2.14.7 SYSCTL Examples

NOTE: These examples are located in the F29x SDK installation from ti.com at the following location:
f29h85x-sdk_X_XX_XX_XX/examples/driverlib/CORE_IF_MULTICORE/sysctl

Cloud access to these examples is available at the following link: [dev.ti.com F29x SDK Examples](https://dev.ti.com/F29x_SDK_Examples).

2.14.7.1 Missing clock detection (MCD) - SINGLE_CORE

FILE: sysctl_ex1_missing_clock_detection.c

This example demonstrates the missing clock detection functionality and the way to handle it. Once the MCD is simulated by disconnecting the OSCCLK to the MCD module an NMI would be generated. This NMI determines that an MCD was generated due to a clock failure which is handled in the ISR.

Before an MCD the clock frequency would be as per device initialization (200Mhz). Post MCD the frequency would move to 10Mhz or INTOSC1.

The example also shows how we can lock the PLL after missing clock, detection, by first explicitly switching the clock source to INTOSC1, resetting the missing clock detect circuit and then re-locking the PLL. Post a re-lock the clock frequency would be 200Mhz but using the INTOSC1 as clock source.

External Connections

- None.

Watch Variables

- *fail* - Indicates that a missing clock was either not detected or was not handled correctly.
- *mcd_clkfail_isr* - Indicates that the missing clock failure caused an NMI to be triggered and called an the ISR to handle it.
- *mcd_detect* - Indicates that a missing clock was detected.

- *result* - Status of a successful handling of missing clock detection

2.14.7.2 XCLKOUT (External Clock Output) Configuration - SINGLE_CORE

FILE: sysctl_ex2_xclkout.c

This example demonstrates how to configure the XCLKOUT pin for observing internal clocks through an external pin, for debugging and testing purposes.

In this example, we are using INTOSC1 as the XCLKOUT clock source and configuring the divider as 8.

Expected frequency of XCLKOUT = (INTOSC1 freq)/8 = 10/8 = 1.25MHz

View the XCLKOUT on GPIO73 using an oscilloscope.

2.14.8 TIMER Examples

NOTE: These examples are located in the F29x SDK installation from ti.com at the following location:

f29h85x-sdk_X_XX_XX_XX/examples/driverlib/CORE_IF_MULTICORE/timer

Cloud access to these examples is available at the following link: [dev.ti.com F29x SDK Examples](https://dev.ti.com/F29x_SDK_Examples).

2.14.8.1 Timer Academy Lab - SINGLE_CORE

FILE: timer_academy_lab.c

This example demonstrates how to use a CPU Timer to blink two LEDs. The timer and the LED GPIOs are each configured within the SysConfig file. The LED GPIO pins are toggled in the CPU Timer interrupt service routine. A global variable is incremented at the end of each timer interrupt.

External Connections

- None.

Watch Variables

- *cpuTimer0IntCount* - CPU Timer interrupt counts.

2.14.8.2 CPU Timers - SINGLE_CORE

FILE: timer_ex1_cputimers.c

This example configures CPU Timer0, 1, and 2 and increments a counter each time the timer asserts an interrupt.

External Connections

- None

Watch Variables

- *cpuTimer0IntCount*
- *cpuTimer1IntCount*
- *cpuTimer2IntCount*

2.14.8.3 CPU Timers - SINGLE_CORE

FILE: timer_ex2_cputimers_syscfg.c

This example configures CPU Timer0, 1, and 2 and increments a counter each time the timer asserts an interrupt.

The interrupt priorities are configured as follows :

- RTINT Threshold = 15
- Timer 0 Interrupt priority = 10 -> RTINT
- Timer 1 Interrupt priority = 20 -> INT
- Timer 2 Interrupt priority = 30 -> INT

Sysconfig inserts the required attributes to the ISR functions to inform the compiler that the function is an interrupt / realtime interrupt.

External Connections

- None

Watch Variables

- cpuTimer0IntCount
- cpuTimer1IntCount
- cpuTimer2IntCount

2.14.9 WATCHDOG Examples

NOTE: These examples are located in the F29x SDK installation from ti.com at the following location: f29h85x-sdk_X_XX_XX_XX/examples/driverlib/CORE_IF_MULTICORE/watchdog

Cloud access to these examples is available at the following link: [dev.ti.com F29x SDK Examples](https://dev.ti.com/F29x_SDK_Examples).

2.14.9.1 Watchdog - SINGLE_CORE

FILE: watchdog_ex1_service.c

This example shows how to service the watchdog or generate a watchdog interrupt using the watchdog. By default the example will generate a watchdog interrupt. To service the watchdog and not generate the interrupt, uncomment the SysCtl_serviceWatchdog() line in the main for loop.

External Connections

- None.

Watch Variables

- ISRCCount - The number of times entered into the watchdog ISR
- loopCount - The number of loops performed while not in ISR

2.14.10 LPM Examples

NOTE: These examples are located in the F29x SDK installation from ti.com at the following location: f29h85x-sdk_X_XX_XX_XX/examples/driverlib/CORE_IF_MULTICORE/lpm

Cloud access to these examples is available at the following link: [dev.ti.com F29x SDK Examples](https://dev.ti.com/F29x_SDK_Examples).

2.14.10.1 Low Power Modes: Device Idle Mode and Wakeup using GPIO - SINGLE_CORE

FILE: lpm_ex1_idlewake_gpio.c

This example puts the device into IDLE mode and then wakes up the device from IDLE using XINT1 which triggers on a falling edge of GPIO0.

The GPIO0 pin must be pulled from high to low by an external agent for wakeup. GPIO0 is configured as an XINT1 pin to trigger an XINT1 interrupt upon detection of a falling edge.

Initially, pull GPIO0 high externally. To wake device from IDLE mode by triggering an XINT1 interrupt, pull GPIO0 low (falling edge). The wakeup process begins as soon as GPIO0 is held low for the time indicated in the device datasheet.

GPIO1 is pulled high before entering the IDLE mode and is pulled low when in the external interrupt ISR.

External Connections

- GPIO0 needs to be pulled low to wake up the device.
- On device wakeup, the GPIO1 will be low and LED1 will start blinking

2.14.10.2 Low Power Modes: Device Idle Mode and Wakeup using Watchdog - SINGLE_CORE

FILE: lpm_ex2_idlewake_watchdog.c

This example puts the device into IDLE mode and then wakes up the device from IDLE using watchdog timer.

The device wakes up from the IDLE mode when the watchdog timer overflows, triggering an interrupt. A pre scalar is set for the watchdog timer to change the counter overflow time.

GPIO1 is pulled high before entering the IDLE mode and is pulled low when in the wakeup ISR.

External Connections

- On device wakeup, the GPIO1 will be low and LED1 will start blinking

2.14.10.3 Low Power Modes: Device Standby Mode and Wakeup using GPIO - SINGLE_CORE

FILE: lpm_ex3_standbywake_gpio.c

This example puts the device into STANDBY mode. If the lowest possible current consumption in STANDBY mode is desired, the JTAG connector must be removed from the device board while the device is in STANDBY mode.

This example puts the device into STANDBY mode and then wakes up the device from STANDBY using an LPM wakeup pin.

The pin GPIO0 is configured as the LPM wakeup pin to trigger a WAKEINT interrupt upon detection of a low pulse. Initially, pull GPIO0 high externally. To wake device from STANDBY mode, pull GPIO0 low for at least (2+QUALSTDBY), OSCCLKS, then pull it high again.

The example then wakes up the device from STANDBY using GPIO0. GPIO0 wakes the device from STANDBY mode when a low pulse (signal goes high->low->high) is detected on the pin. This pin must be pulsed by an external agent for wakeup.

GPIO1 is pulled high before entering the STANDBY mode and is pulled low when in the wakeup ISR.

External Connections

- GPIO0 needs to be pulled low to wake up the device.
- On device wakeup, the GPIO1 will be low and LED1 will start blinking

2.14.10.4 Low Power Modes: Device Standby Mode and Wakeup using Watchdog - SINGLE_CORE

FILE: lpm_ex4_standbywake_watchdog.c

This example puts the device into STANDBY mode. If the lowest possible current consumption in STANDBY mode is desired, the JTAG connector must be removed from the device board while the device is in STANDBY mode.

This example puts the device into STANDBY mode then wakes up the device from STANDBY using watchdog timer.

The device wakes up from the STANDBY mode when the watchdog timer overflows triggering an interrupt. In the ISR, the GPIO1 is pulled low. the GPIO1 is toggled to indicate the device is out of STANDBY mode. A pre scalar is set for the watchdog timer to change the counter overflow time.

GPIO1 is pulled high before entering the STANDBY mode and is pulled low when in the wakeup ISR.

External Connections

- On device wakeup, the GPIO1 will be low and LED1 will start blinking

2.15 SYSCCTRL Registers

This Section describes the SYSCCTRL Registers.

2.15.1 SYSCCTRL Base Address Table

Table 2-19. SYSCCTRL Base Address Table

Structure	DriverLib Name	Base Address	Frame Applicable	CPU1	CPU2	CPU3	RTDMA1	RTDMA2	HSM	Pipeline Protected
DEV_CFG_REGS [†]	DEVCFG_BASE	0x3018_0000	-	YES	YES	YES	-	-	YES	YES
MEMSS_L_CONFIG_REGS [†]	MEMSSLCFG_BASE	0x301D_8000	-	YES	YES	YES	-	-	YES	YES
MEMSS_C_CONFIG_REGS [†]	MEMSSCCFG_BASE	0x301D_8400	-	YES	YES	YES	-	-	YES	YES

Table 2-19. SYSCTRL Base Address Table (continued)

Structure	DriverLib Name	Base Address	Frame Applicable	CPU1	CPU2	CPU3	RTDMA1	RTDMA2	HSM	Pipeline Protected
MEMSS_M_CONFIG_REGS¹	MEMSSMCFG_BASE	0x301D_8800	-	YES	YES	YES	-	-	YES	YES
MEMSS_MISCI_REGS¹	MEMSSMISCI_BASE	0x301D_8E00	-	YES	YES	YES	-	-	YES	YES

XINT_REGS	XINT_BASE	0x3027_0000	-	YES	YES	YES	-	-	-	YES

- (1) Registers writeable by CPU1.LINK0, CPU1.LINK1, CPU1.LINK2 only. All CPUs can read all registers in all LINKs. Debug write access only allowed if Zone0 or Zone1 are enabled for full debug by all CPUs. Debug reads always allowed. Register Read/Write access by HSM.

2.15.2 DEV_CFG_REGS Registers

Table 2-20 lists the memory-mapped registers for the DEV_CFG_REGS registers. All register offset addresses not listed in Table 2-20 should be considered as reserved locations and the register contents should not be modified.

Table 2-20. DEV_CFG_REGS Registers

Offset	Acronym	Register Name	Protection
0h	DEVCFGLOCK1	Lock bit for PERxSYSCONFIG0-31 registers	PARITY
4h	DEVCFGLOCK2	Lock bit for DEVCFG registers	PARITY
8h	DEVCFGLOCK3	Lock bit for PERxSYSCONFIG32-63 registers	PARITY
Ch	DEVCFGLOCK4	Lock bit for PERxSYSCONFIG64-95 registers	PARITY

Table 2-20. DEV_CFG_REGS Registers (continued)

Offset	Acronym	Register Name	Protection
7C4h	ADC_GLOBAL_REGS	PER129SYSCONFIG - Peripheral System Configuration for ADC_GLOBAL_REGS	PARITY
7C8h	Error_Aggregator	PER130SYSCONFIG - Peripheral System Configuration for Error_Aggregator	PARITY
7CCh	ESM	PER131SYSCONFIG - Peripheral System Configuration for ESM ESMCPU1/2/3 and ESMSYS	PARITY
7E4h	PARITY_TEST	Enables parity test	

Complex bit access types are encoded to fit into small table cells. [Table 2-21](#) shows the codes that are used for access types in this section.

Table 2-21. DEV_CFG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1C	W1C	Write 1 to clear
W1S	W1S	Write 1 to set
WOnce	WOnce	Write Write once
WSonce	WSonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

2.15.2.1 DEVCFGLOCK1 Register (Offset = 0h) [Reset = 00000000h]

DEVCFGLOCK1 is shown in [Figure 2-29](#) and described in [Table 2-22](#).

Return to the [Summary Table](#).

Lock bit for CPUSELx registers

The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed

Note:

Any SOnce bit in this register, once set can only be cleared through a CPU1.SYSRSn. Write of 0 to any bit of this register has no effect

2.15.2.5 DEVCFGLOCK5 Register (Offset = 10h) [Reset = 00000000h]

DEVCFGLOCK5 is shown in [Figure 2-33](#) and described in [Table 2-26](#).

Return to the [Summary Table](#).

Lock bit for DEVCFG registers

Note:

[1] The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed

[2] Any SOnce bit in this register, once set can only be cleared through a CPU1.SYSRSn. Write of 0 to any bit of this register has no effect

MCUCNFLOCK1 is shown in [Figure 2-59](#) and described in [Table 2-52](#).

Return to the [Summary Table](#).

Lock bit for MCUCNFx registers

The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed

Note:

Any SOnce bit in this register, once set can only be cleared through a CPU1.SYSRSn. Write of 0 to any bit of this register has no effect

Table 2-57. SICCONFIG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	TIMEOUT	R/W	FFFFh	Safety Interconnect (SIC) READY TIMEOUT value, in terms of number of clock cycles. This is a 16-bit value common across multiple CPU, DMA or any other initiator on the inyterconnect. This value controls the input to the C29 CPU/SIC to detect bus-hang condition. Due to a fault, if ready is pulled low by the endpoint longer than number of clock cycles programmed in this register, then timeout logic inside SIC will generate abort access to endpoint and aborts the ongoing access on bus, communicates as error on the error interface bus. Reset type: XRSn
15-1	RESERVED	R-0	0h	Reserved
0	Enable	R/W	0h	Safety Interconnect (SIC) Enable Reset type: XRSn

Table 2-87. CLKSRCCTL1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1-0	OSCCLKSRCSEL	R/W	0h	Oscillator Clock Source Select Bit: This bit selects the source for OSCCLK. 00 = INTOSC2 (default on reset) 01 = External Oscillator (XTAL) 10 = INTOSC1 11 = reserved (default to INTOSC1) At power-up or after an XRSn, INTOSC2 is selected by default. Whenever the user changes the clock source using these bits, the SYSPLLMULT[13:0] register will be forced to zero and the PLL will be bypassed and powered down. This prevents potential PLL overshoot. The user will then have to write to the SYSPLLMULT register to configure the appropriate multiplier. The user must wait 10 OSCCLK cycles before writing to SYSPLLMULT or disabling the previous clock source to allow the change to complete.. Notes: [1] INTOSC1 is recommended to be used only after missing clock detection. If user wants to re-lock the PLL with INTOSC1 (the back-up clock source) after missing clock is detected, he can do a MCLKCLR and lock the PLL. Reset type: XRSn

2.15.2.67 CLKSRCCTL2 Register (Offset = 534h) [Reset = 00000000h]

CLKSRCCTL2 is shown in [Figure 2-95](#) and described in [Table 2-88](#).

Return to the [Summary Table](#).

Clock Source Control register-2

This memory mapped register requires a delay of 69 SYSCLK cycles between subsequent writes to the register, otherwise a second write can be lost. This delay can be realized by adding 69 NOP instructions.

Table 2-232. PARITY_TEST Register Field Descriptions

Bit	Field	Type	Reset	Description
31-4	RESERVED	R	0h	Reserved
3-0	TESTEN	R/W	0h	1010: Parity test feature is enabled All other values: Parity test feature is disabled Note: (1) When the parity test feature is enabled, actual registers are not accessible in the memory map. Instead, the parity values (final XOR output indicating the parity error) are accessible. Parity is computed for every byte and the corresponding parity error value is available at the bit-0 of every byte. Value of '1' written to the parity bit after enabling the parity test feature can be used to inject the error by inverting the stored parity value. (2) It is recommended to leave the field as 0101 or 0000 after completing the parity test. Reset type: SYSRSn

2.15.3 MEMSS_L_CONFIG_REGS Registers

Table 2-233 lists the memory-mapped registers for the MEMSS_L_CONFIG_REGS registers. All register offset addresses not listed in Table 2-233 should be considered as reserved locations and the register contents should not be modified.

Table 2-233. MEMSS_L_CONFIG_REGS Registers

2.15.5 MEMSS_M_CONFIG_REGS Registers

Table 2-309 lists the memory-mapped registers for the MEMSS_M_CONFIG_REGS registers. All register offset addresses not listed in Table 2-309 should be considered as reserved locations and the register contents should not be modified.

Table 2-309. MEMSS_M_CONFIG_REGS Registers

Offset	Acronym	Register Name	Protection
0h	M0_MEM_CONFIG	M0 Memory Configuration Register	PARITY
4h	M0_MEM_CONFIG_LOCK	Temporary Lock for M0 Memory Configuration Register	PARITY
8h	M0_MEM_CONFIG_COMMIT	Permanent Lock for M0 Memory Configuration Register	PARITY

Complex bit access types are encoded to fit into small table cells. Table 2-310 shows the codes that are used for access types in this section.

**Table 2-310. MEMSS_M_CONFIG_REGS Access
Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value

2.15.5.1 M0_MEM_CONFIG Register (Offset = 0h) [Reset = 00000000h]

0	M0_MEM_CONFIG_LOCK	WSonce	0h	When set, locks the M0_MEM_CONFIG_LOCK register. This bit cannot be cleared, except by reset. 0 : M0_MEM_CONFIG is modifiable 1 : M0_MEM_CONFIG is committed permanently Reset type: XRSn

2.15.6 MEMSS_MISCI_REGS Registers

Table 2-314 lists the memory-mapped registers for the MEMSS_MISCI_REGS registers. All register offset addresses not listed in Table 2-314 should be considered as reserved locations and the register contents should not be modified.

Table 2-314. MEMSS_MISCI_REGS Registers

Offset	Acronym	Register Name	Protection
0h	MEM_DLB_CONFIG	Dataline buffer enable	PARITY
4h	MEM_DLB_CONFIG_LOCK	Temporary Lock for DLB Configuration Register	PARITY
8h	MEM_DLB_CONFIG_COMMIT	Permament Lock for DLB Configuration Register	PARITY
10h	PERI_MEM_TEST_LOCK	Peripheral Memory Test Lock Register	PARITY
14h	PERI_MEM_TEST_CONTROL	Peripheral Memory Test control Register	PARITY
1FCh	PARITY_TEST	Enabling the parity test feature	

Complex bit access types are encoded to fit into small table cells. Table 2-315 shows the codes that are used for access types in this section.

Table 2-315. MEMSS_MISCI_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
WOnce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

2.15.6.1 MEM_DLB_CONFIG Register (Offset = 0h) [Reset = 0000007Fh]

MEM_DLB_CONFIG is shown in [Figure 2-315](#) and described in [Table 2-316](#).

Table 2-321. PARITY_TEST Register Field Descriptions

Bit	Field	Type	Reset	Description
31-4	RESERVED	R	0h	Reserved
3-0	TESTEN	R/W	0h	1010: Parity test feature is enabled All other values: Parity test feature is disabled Note: (1) When the parity test feature is enabled, acutal registers are not accessible in the memory map. Instead, the parity values (final XOR output indicating the parity error) are accessible. Parity is computed for every byte and the correponding parity error value is available at the bit-0 of every byte. Value of '1' written to the parity bit after enabling the parity test feature can be used to inject the error by inverting the stored parity value. (2) It is recommended to leave the field as 0101 or 0000 after completing the parity test. Reset type: XRSn

2.15.7 SYNCBRIDGEMPU_REGS Registers

Table 2-322 lists the memory-mapped registers for the SYNCBRIDGEMPU_REGS registers. All register offset addresses not listed in Table 2-322 should be considered as reserved locations and the register contents should not be modified.

Table 2-322. SYNCBRIDGEMPU_REGS Registers

Offset	Acronym	Register Name	Protection
0h + formula	MPUR_START_j	MPU Region Start Address	LOCK: MPUR_LOCK.LOCK

<i>-n</i>		Value after reset or the default value
Register Array Variables		
<i>i,j,k,l,m,n</i>		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
<i>y</i>		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

2.15.8.1 CPUSYSLOCK1 Register (Offset = 0h) [Reset = 00000000h]

CPUSYSLOCK1 is shown in [Figure 2-329](#) and described in [Table 2-334](#).

Return to the [Summary Table](#).

Lock bit for CPUSYS registers

Notes:

[1] Any bit in this register, once set can only be cleared through a CPU1.SYSRSn. Write of 0 to any bit of this register has no effect

[2] The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed

Table 2-356. SIMRESET Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	KEY	R-0/W	0h	Write to this register succeeds only if this field is written with a value of 0xa5a5 Note: [1] Due to this KEY, only 32-bit writes will succeed (provided the KEY matches). 16-bit writes to the upper or lower half of this register will be ignored Reset type: XRSn
15-2	RESERVED	R-0	0h	Reserved
1	XRSn	R-0/W1S	0h	Writing a 1 to this field generates a XRSn like reset. Writing a 0 has no effect. Note: Writing to this pin will pull the XRSn pin low for 512 INTOSC1 clock cycles. This bit is implemented only for SIMRESET copy of CPU1. For CPU2,3,4,5,6 this is a reserved bit. No effect on writes, and Read=0 Reset type: XRSn
0	RESERVED	R-0/W1S	0h	Reserved

2.15.8.24 PARITY_TEST_ALT2 Register (Offset = A8h) [Reset = 00000000h]

PARITY_TEST_ALT2 is shown in [Figure 2-352](#) and described in [Table 2-357](#).

Return to the [Summary Table](#).

Enables parity test

Table 2-357. PARITY_TEST_ALT2 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-4	RESERVED	R	0h	Reserved
3-0	TESTEN	R/W	0h	1010: Parity test feature is enabled All other values: Parity test feature is disabled Note: (1) When the parity test feature is enabled, actual registers are not accessible in the memory map. Instead, the parity values (final XOR output indicating the parity error) are accessible. Parity is computed for every byte and the corresponding parity error value is available at the bit-0 of every byte. Value of '1' written to the parity bit after enabling the parity test feature can be used to inject the error by inverting the stored parity value. (2) It is recommended to leave the field as 0101 or 0000 after completing the parity test. Reset type: SYSRSn

2.15.9 CPU_PER_CFG_REGS Registers

Table 2-358 lists the memory-mapped registers for the CPU_PER_CFG_REGS registers. All register offset addresses not listed in Table 2-358 should be considered as reserved locations and the register contents should not be modified.

Table 2-358. CPU_PER_CFG_REGS Registers

Complex bit access types are encoded to fit into small table cells. [Table 2-359](#) shows the codes that are used for access types in this section.

Table 2-359. CPU_PER_CFG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

2.15.9.1 CPUPERCFGLOCK1 Register (Offset = 0h) [Reset = 00000000h]

CPUPERCFGLOCK1 is shown in [Figure 2-353](#) and described in [Table 2-360](#).

Return to the [Summary Table](#).

Lock bit for CPUx_PER_CFG registers

Notes:

[1] Any bit in this register, once set can only be cleared through a CPUx.SYSRSn. Write of 0 to any bit of this register has no effect

[2] The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed

Table 2-410. PARITY_TEST_ALT1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-4	RESERVED	R	0h	Reserved
3-0	TESTEN	R/W	0h	1010: Parity test feature is enabled All other values: Parity test feature is disabled Note: (1) When the parity test feature is enabled, actual registers are not accessible in the memory map. Instead, the parity values (final XOR output indicating the parity error) are accessible. Parity is computed for every byte and the corresponding parity error value is available at the bit-0 of every byte. Value of '1' written to the parity bit after enabling the parity test feature can be used to inject the error by inverting the stored parity value. (2) It is recommended to leave the field as 0101 or 0000 after completing the parity test. Reset type: SYSRSn

2.15.10 WD_REGS Registers

Table 2-411 lists the memory-mapped registers for the WD_REGS registers. All register offset addresses not listed in Table 2-411 should be considered as reserved locations and the register contents should not be modified.

Table 2-411. WD_REGS Registers

Offset	Acronym	Register Name	Protection
44h	SCSR	System Control & Status Register	
46h	WDCNTR	Watchdog Counter Register	
4Ah	WDKEY	Watchdog Reset Key Register	
50h	SYNCBUSYWD	SYNCBUSY status for Watchdog Register	
52h	WDCR	Watchdog Control Register	
54h	WDWCR	Watchdog Windowed Control Register	

Complex bit access types are encoded to fit into small table cells. Table 2-412 shows the codes that are used for access types in this section.

Table 2-412. WD_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

2.15.10.1 SCSR Register (Offset = 44h) [Reset = 0005h]

SCSR is shown in [Figure 2-404](#) and described in [Table 2-413](#).

Return to the [Summary Table](#).

RESERVED					WDINTS	WDENINT	WDOVERRIDE
R-0-0h					R-1h	R/W-0h	R/W1S-1h

Table 2-413. SCSR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-3	RESERVED	R-0	0h	Reserved
2	WDINTS	R	1h	Watchdog Interrupt Status This bit indicates the state of the active-low watchdog interrupt signal (synchronized to SYSCLK). If the watchdog interrupt is used to wake the system from a low-power mode, then that mode should only be entered while this bit is high. Likewise, this bit must go high before the watchdog can be safely disabled and re-enabled. 0h = The watchdog interrupt signal is active. 1h = The watchdog interrupt signal is inactive. Reset type: SYSRSn
1	WDENINT	R/W	0h	Watchdog Interrupt Enable/Reset Disable This bit determines whether the watchdog triggers an interrupt (WAKE/WDOG) or a reset (WDRS) when the counter expires. The error event is also generated to ESM on counter expiration 0h = Counter expiration triggers a reset. This is the default state on power-up and after any system reset. 1h = Counter expiration triggers an interrupt. Reset type: SYSRSn
0	WDOVERRIDE	R/W1S	1h	Watchdog Enable Lock Writing a 1 to this bit clears it and locks the WDDIS bit in the WDCR register. The bit will remain in this state until the next system reset. Reads of this bit return its current value. Writing a 0 to this bit has no effect. Reset type: SYSRSn

2.15.10.2 WDCNTR Register (Offset = 46h) [Reset = 0000h]

WDCNTR is shown in [Figure 2-405](#) and described in [Table 2-414](#).

Return to the [Summary Table](#).

Table 2-417. WDCR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-12	RESERVED	R-0	0h	Reserved
11-8	WDPRECLKDIV	R/W	0h	Watchdog Clock Pre-divider These bits determine the watchdog clock pre-divider, which is the first of the two dividers between INTOSC1 and the watchdog counter clock (WDCLK). The frequency of WDCLK is given by the formulas: $PREDIVCLK = INTOSC1 / \text{Pre-divider}$ $WDCLK = PREDIVCLK / \text{Prescaler}$ The watchdog reset or interrupt pulse is 512 INTOSC1 cycles long, so the counter period must be longer. To guarantee this, the product of the prescaler and pre-divider must be greater than or equal to four. The default pre-divider value is 512. Reset type: IORSn
7	RESERVED	R/W1S	0h	Reserved
6	WDDIS	R/W	0h	Watchdog Disable Setting this bit disables the watchdog module. Clearing this bit enables the watchdog module. This bit can be locked by the WDOVERRIDE bit in the SCSR register. The watchdog is enabled on reset. Reset type: IORSn
5-3	WDCHK	R-0/W	0h	Watchdog Check Bits During any write to this register, these bits must be written with the value 101 (binary). Writing any other value will immediately trigger the watchdog reset or interrupt. Reset type: IORSn
2-0	WDPS	R/W	0h	Watchdog Clock Prescaler These bits determine the watchdog clock prescaler, which is the second of the two dividers between INTOSC1 and the watchdog counter clock (WDCLK). The frequency of WDCLK is given by the formulas: $PREDIVCLK = INTOSC1 / \text{Pre-divider}$ $WDCLK = PREDIVCLK / \text{Prescaler}$ The watchdog reset or interrupt pulse is 512 INTOSC1 cycles long, so the counter period must be longer. To guarantee this, the product of the prescaler and pre-divider must be greater than or equal to four. The default prescaler value is 1. Reset type: IORSn

2.15.10.6 WDWCR Register (Offset = 54h) [Reset = 0000h]

WDWCR is shown in [Figure 2-409](#) and described in [Table 2-418](#).

Return to the [Summary Table](#).

Table 2-421. TIM Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	MSW	R/W	0h	CPU-Timer Counter Registers The TIMH register holds the high 16 bits of the current 32-bit count of the timer. The TIMH:TIM decrements by one every (TDDRH:TDDR+1) clock cycles, where TDDRH:TDDR is the timer prescale dividedown value. When the TIMH:TIM decrements to zero, the TIMH:TIM register is reloaded with the period value contained in the PRDH:PRD registers. The timer interrupt (TINT) signal is generated. Reset type: SYSRSn
15-0	LSW	R/W	FFFFh	CPU-Timer Counter Registers The TIM register holds the low 16 bits of the current 32-bit count of the timer. The TIMH:TIM decrements by one every (TDDRH:TDDR+1) clock cycles, where TDDRH:TDDR is the timer prescale dividedown value. When the TIMH:TIM decrements to zero, the TIMH:TIM register is reloaded with the period value contained in the PRDH:PRD registers. The timer interrupt (TINT) signal is generated. Reset type: SYSRSn

2.15.11.2 PRD Register (Offset = 4h) [Reset = 0000FFFFh]

PRD is shown in [Figure 2-411](#) and described in [Table 2-422](#).

Return to the [Summary Table](#).

Table 2-422. PRD Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	MSW	R/W	0h	CPU-Timer Period Registers The PRDH register holds the high 16 bits of the 32-bit period. When the TIMH:TIM decrements to zero, the TIMH:TIM register is reloaded with the period value contained in the PRDH:PRD registers, at the start of the next timer input clock cycle (the output of the prescaler). The PRDH:PRD contents are also loaded into the TIMH:TIM when you set the timer reload bit (TRB) in the Timer Control Register (TCR). Reset type: SYSRStn
15-0	LSW	R/W	FFFFh	CPU-Timer Period Registers The PRD register holds the low 16 bits of the 32-bit period. When the TIMH:TIM decrements to zero, the TIMH:TIM register is reloaded with the period value contained in the PRDH:PRD registers, at the start of the next timer input clock cycle (the output of the prescaler). The PRDH:PRD contents are also loaded into the TIMH:TIM when you set the timer reload bit (TRB) in the Timer Control Register (TCR). Reset type: SYSRStn

2.15.11.3 TCR Register (Offset = 8h) [Reset = 0001h]

TCR is shown in [Figure 2-412](#) and described in [Table 2-423](#).

Return to the [Summary Table](#).

CPU-Timer, Control Register

Figure 2-412. TCR Register

15	14	13	12	11	10	9	8
TIF	TIE	RESERVED		FREE	SOFT	RESERVED

7	6	5	4	3	2	1	0
RESERVED		TRB	TSS	RESERVED			
R-0h		R/W-0h	R/W-0h	R-1h			

Table 2-423. TCR Register Field Descriptions

Bit	Field	Type	Reset	Description
15	TIF	R/W1C	0h	CPU-Timer Overflow Flag. TIF indicates whether a timer overflow has happened since TIF was last cleared. TIF is not cleared automatically and does not need to be cleared to enable the next timer interrupt. Reset type: SYSRSn 0h (R/W) = The CPU-Timer has not decremented to zero. Writes of 0 are ignored. 1h (R/W) = This flag gets set when the CPU-timer decrements to zero. Writing a 1 to this bit clears the flag.
14	TIE	R/W	0h	CPU-Timer Interrupt Enable. Reset type: SYSRSn 0h (R/W) = The CPU-Timer interrupt is disabled. 1h (R/W) = The CPU-Timer interrupt is enabled. If the timer decrements to zero, and TIE is set, the timer asserts its interrupt request.
13-12	RESERVED	R	0h	Reserved
11	FREE	R/W	0h	If the FREE bit is set to 1, then, upon a software breakpoint, the timer continues to run. If FREE is 0, then the SOFT bit controls the emulation behavior. Reset type: SYSRSn 0h (R/W) = Stop after the next decrement of the TIMH:TIM (hard stop) (SOFT bit controls the emulation behavior) 1h (R/W) = Free Run (SOFT bit is don't care, counter is free running)
10	SOFT	R/W	0h	If the FREE bit is set to 1, then, upon a software breakpoint, the timer continues to run (that is, free runs). In this case, SOFT is a don't care. But if FREE is 0, then SOFT takes effect. Reset type: SYSRSn 0h (R/W) = Stop after the next decrement of the TIMH:TIM (hard stop). (ONLY if FREE=0, if FREE=1 this bit is don't care) 1h (R/W) = Stop after the TIMH:TIM decrements to 0 (soft stop) In the SOFT STOP mode, the timer generates an interrupt before shutting down (since reaching 0 is the interrupt causing condition). (ONLY if FREE=0, if FREE=1 this bit is don't care)
9-6	RESERVED	R	0h	Reserved

Table 2-423. TCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	TRB	R/W	0h	Timer reload Reset type: SYSRSn 0h (R/W) = The TRB bit is always read as zero. Writes of 0 are ignored. 1h (R/W) = When you write a 1 to TRB, the TIMH:TIM is loaded with the value in the PRDH:PRD, and the prescaler counter (PSCH:PSC) is loaded with the value in the timer dividedown register (TDDRH:TDDR).
4	TSS	R/W	0h	CPU-Timer stop status bit. TSS is a 1-bit flag that stops or starts the CPU-timer. Reset type: SYSRSn 0h (R/W) = Reads of 0 indicate the CPU-timer is running. To start or restart the CPU-timer, set TSS to 0. At reset, TSS is cleared to 0 and the CPU-timer immediately starts. 1h (R/W) = Reads of 1 indicate that the CPU-timer is stopped. To stop the CPU-timer, set TSS to 1.
3-0	RESERVED	R	1h	Reserved

2.15.11.4 TPR Register (Offset = Ch) [Reset = 0000h]

TPR is shown in [Figure 2-413](#) and described in [Table 2-424](#).

Return to the [Summary Table](#).

Table 2-424. TPR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	PSC	R	0h	CPU-Timer Prescale Counter. These bits hold the current prescale count for the timer. For every timer clock source cycle that the PSCH:PSC value is greater than 0, the PSCH:PSC decrements by one. One timer clock (output of the timer prescaler) cycle after the PSCH:PSC reaches 0, the PSCH:PSC is loaded with the contents of the TDDRH:TDDR, and the timer counter register (TIMH:TIM) decrements by one. The PSCH:PSC is also reloaded whenever the timer reload bit (TRB) is set by software. The PSCH:PSC can be checked by reading the register, but it cannot be set directly. It must get its value from the timer divide-down register (TDDRH:TDDR). At reset, the PSCH:PSC is set to 0. Reset type: SYSRSn
7-0	TDDR	R/W	0h	CPU-Timer Divide-Down. Every (TDDRH:TDDR + 1) timer clock source cycles, the timer counter register (TIMH:TIM) decrements by one. At reset, the TDDRH:TDDR bits are cleared to 0. To increase the overall timer count by an integer factor, write this factor minus one to the TDDRH:TDDR bits. When the prescaler counter (PSCH:PSC) value is 0, one timer clock source cycle later, the contents of the TDDRH:TDDR reload the PSCH:PSC, and the TIMH:TIM decrements by one. TDDRH:TDDR also reloads the PSCH:PSC whenever the timer reload bit (TRB) is set by software. Reset type: SYSRSn

2.15.11.5 TPRH Register (Offset = Eh) [Reset = 0000h]

TPRH is shown in [Figure 2-414](#) and described in [Table 2-425](#).

2.15.12 XINT_REGS Registers

Table 2-426 lists the memory-mapped registers for the XINT_REGS registers. All register offset addresses not listed in Table 2-426 should be considered as reserved locations and the register contents should not be modified.

Table 2-426. XINT_REGS Registers

Offset	Acronym	Register Name	Protection
0h	XINT1CR	XINT1 configuration register	
2h	XINT2CR	XINT2 configuration register	
4h	XINT3CR	XINT3 configuration register	
6h	XINT4CR	XINT4 configuration register	
8h	XINT5CR	XINT5 configuration register	
10h	XINT1CTR	XINT1 counter register	
12h	XINT2CTR	XINT2 counter register	
14h	XINT3CTR	XINT3 counter register	

Complex bit access types are encoded to fit into small table cells. Table 2-427 shows the codes that are used for access types in this section.

Table 2-427. XINT_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

2.15.12.1 XINT1CR Register (Offset = 0h) [Reset = 0000h]

Chapter 3

ROM Code and Peripheral Booting

This chapter explains the boot procedure, the available boot modes, and the various details of the ROM code including memory maps, initializations, reset handling, and status information.

3.1 Introduction.....	744
3.2 Device Boot Sequence.....	745
3.3 Device Boot Modes.....	746
3.4 Device Boot Configurations.....	748
3.5 Device Boot Flow Diagrams.....	754
3.6 Device Reset and Exception Handling.....	760
3.7 Boot ROM Description.....	764
3.8 Software.....	783

3.1 Introduction

This chapter explains the boot read-only memory (ROM) code functionality for the C29x CPU core's, including the boot procedure. This chapter also discusses the functions and features of the boot ROM code, and provides details about the ROM memory-map contents. On every reset, the device executes a boot sequence in the ROM depending on the reset type and boot configuration. This sequence initializes the device to run the application code. For the CPU, the boot ROM also contains peripheral bootloaders that can be used to load an application into RAM. These bootloaders can be disabled for safety or security purposes.

See [Table 3-1](#) for details on available boot features for the C29x CPU. Additionally, [Table 3-2](#) shows the sizes of the various ROMs on the device.

Various tables are provided in ROM for use in software library, refer to [Section 3.7.7](#) for more details.

Table 3-1. Boot System Overview

Boot Feature	CPU
Initial boot process	Device reset
Boot mode selection	GPIOs
Boot modes supported	Flash boot RAM boot Wait boot Parallel IO CAN CAN-FD I2C SPI UART

Table 3-2. ROM Memory

ROM	Size
CPU1 boot ROM	128KB
CPU2 boot ROM	32KB
CPU3 boot ROM	32KB

CPU2 and CPU3 do not have any BootROM code and just contains default NMI handler. During initialization, application needs to re-assign the handler to override the default handler. The CPU2/3 default NMI handlers point to infinite while loop. This section further explains in detail on the CPU1 Boot ROM flow.

3.1.1 ROM Related Collateral

3.2 Device Boot Sequence

[Table 3-3](#) describes the general boot ROM procedure each time the CPU1 core is reset.

During boot, boot ROM code updates a boot status location in RAM that details the actions taken during this process. Refer to [Section 3.7.11](#) for more details.

Table 3-3. CPU1 Boot ROM Sequence

Step	CPU1 Action
1	Flash Read Interface (FRI) wait state configuration
2	Poll for pattern from HSM
3	Enable Watchdog
4	Zone0 full debug password configured from TI-OTP into SSU registers
5	UID (Unique ID) is configured from TI-OTP into SSU registers
6	On PORESETn only, All CPU RAMs (LPAX, LDAX, CPAX and CDAX) are initialized
7	Critical Trims (APLL, PMM, OSC, Flash) are loaded from TI-OTP and device configuration registers are programmed
8	ESM configurations for Group0 error events are locked and committed
9	SIC (Safe Interconnect) is enabled
10	UPP (User Protection Policy) revision from SECCFG is configured into SSU register
11	Error status pin is configured with input from SECCFG, if the input from SECCFG is invalid then no error status pin configuration is done. User can configure the error status pin in the application code
12	External crystal power-up if enabled in SECCFG
13	Configure the device configurations from TI-OTP into DCx registers
14	Load non-critical (ADC, DAC) trims
15	SSU configurations based on SECCFG inputs which include : 1. SSU register self-test 2. SSU register configurations
16	Lock DCx (Device Configuration), PARTID, MCUCNF26 and PERxSYSCONFIG (Peripheral System Configuration) registers
17	Wait for RAM initialization, done only on PORESETn
18	Clear PORRESETn and XRSn reset cause on PORESETn and only clear XRSn reset cause on XRSn
19	Pull-ups are enabled on unbonded IOs
20	The boot mode GPIO pins are polled to determine the boot mode to run. Boot loader is executed based on boot mode/configurations. Refer to Section 3.5.2 for a flow chart of the boot sequences.
21	RAMOPEN for LINK1 which includes: LPA0-1 and LDA0-7
22	Lock and Commit LINK1 RAMOPEN by writing to SSU registers based on SECCFG inputs
23	APR's (Access Protection Regions) are set from SECCFG configurations
24	Disable watchdog for Link1 bootloaders execution
25	Bootloader process under Link1 execution
26	Clear Link1 RAMOPEN
27	Jump to C29x CPU1 Application

3.3 Device Boot Modes

This section explains the default boot modes, as well as all the available custom boot modes supported on this device. The boot ROM uses the boot mode select, general purpose input/output (GPIO) pins to determine the boot mode configuration.

3.3.1 Default Boot Modes

[Table 3-4](#) shows the boot mode options available for selection by the default boot mode select pins. Users have the option to program the device to customize the boot modes selectable in the boot-up table as well as the boot mode select pin GPIOs used. Default BMSP (Boot Mode Select Pin) used are GPIO72 (BMSP1) and GPIO84 (BMSP0).

Table 3-4. Device Default Boot Modes

Boot Mode	GPIO72 (Default boot mode select pin 1)	GPIO84 (Default boot mode select pin 0)
Parallel IO	0	0
UART	0	1
CAN	1	0
Flash	1	1

Refer to [Section 3.4](#) for details of boot configurations.

Refer to [Section 3.7.8.2](#) for details of the boot modes that use a peripheral boot loader.

Refer to [Section 3.7.9](#) for GPIOs used for selecting the boot modes.

Note

All the peripheral boot modes that are supported use the first instance of the peripheral module (SPIA, I2CA, CANA, and so forth). Whenever these boot modes are referred to in this chapter, such as SPI boot, the mode is actually referring to the first module instance, which means the SPI boot on the SPIA port. The same applies to the other peripheral boot modes.

3.3.2 Custom Boot Modes

Once the user programs a custom boot table in SECCFG, an entry in the custom table is used for booting. Users can customize the boot mode select pins in the end system design by programming the BOOTPIN_CONFIG location in SECCFG. This allows customers to use 0, 1, 2, or 3 boot mode select pins as needed. [Table 3-5](#) show the options for various boot modes.

Note

All peripheral boot modes supported in [Table 3-5](#) use the first instance of the peripheral modules (that is SPIA, I2CA, and so on).

Table 3-5. CPU1 Boot Modes

Boot Mode Number	Boot Modes
0	Parallel
1	UART
2	CAN
3	Flash
4	Wait
5	RAM
6	SPI
7	I2C
8	CAN-FD

The boot definition table can also be customized to indicate which location to boot from by programming the boot mode definition table in the BOOTDEF location of SECCFG. [Section 3.4.2](#) describes how the BOOTDEF locations can be configured. More details on the GPIO assignments for default/alternate boot option is described in [Section 3.7.9](#).

Table 3-6. Custom Boot Options

Boot Mode	Default/Alternate	BOOTDEF Value
PARALLEL	Default	0x00
	Alternate1	0x20
UART	Default	0x01
	Alternate1	0x21
	Alternate2	0x41
	Alternate3	0x61
	Alternate4	0x81
CAN	Default	0x02
	Alternate1	0x22
	Alternate2	0x42
	Alternate3	0x62
FLASH	Default	0x03
WAIT	Default	0x04
RAM	Default	0x05
	Alternate1	0x25
SPI	Default	0x06
	Alternate1	0x26
	Alternate2	0x46
	Alternate3	0x66

Table 3-6. Custom Boot Options (continued)

Boot Mode	Default/Alternate	BOOTDEF Value
I2C	Default	0x07
	Alternate1	0x27
	Alternate2	0x47
	Alternate3	0x67
CAN-FD	Default	0x08
	Alternate1	0x28
	Alternate2	0x48
	Alternate3	0x68

3.4 Device Boot Configurations

This section details what boot configurations are available and how to configure them. This device supports from zero boot mode select pins up to three boot mode select pins and from one configured boot mode up to eight configured boot modes.

To change and configure the device from the default settings to custom settings for your application, use the following process:

1. Determine all the various ways you want application to be able to boot. (For example: Primary boot option of Flash boot for your main application, secondary boot option of CAN boot for firmware updates, tertiary boot option of SPI boot for debugging, and so on.)
2. Based on the number of boot modes needed, determine how many boot mode select pins (BMSPs) are required to select between your selected boot modes. (For example: Two BMSPs are required to select between three boot mode options.)
3. Assign the required BMSPs to a physical GPIO pin. (For example, BMSP0 to GPIO10, BMSP1 to GPIO51, and BMSP2 left as default that is disabled.). Refer to [Section 3.4.1](#) for all the details on performing these configurations.
4. Assign the determined boot mode definitions to indexes in your custom boot table that correlate to the decoded value of the BMSPs. For example, BOOTDEF0 = Boot to Flash, BOOTDEF1 = CAN Boot, BOOTDEF2 = SPI Boot; all other BOOTDEFx remain as default/nothing). Refer to [Section 3.4.2](#) for all the details on setting up and configuring the custom boot mode table.

Additionally, [Section 3.4.3](#) provides some example use cases on how to configure the boot mode select pins and custom boot tables.

3.4.1 Configuring Boot Mode Pins

This section explains how the boot mode select pins are customized by the user, by programming the BOOTPIN_CONFIG location (refer to [Table 3-7](#)), in the user-configurable Flash SECCFG sector. The location in the SECCFG sector is BOOTPIN-CONFIG. When debugging, EMU_BOOTPIN_CONFIG register in SSU_GEN_REGS is the emulation equivalent of BOOTPIN_CONFIG, and can be programmed to experiment with different boot modes without writing to seccfg. The device can be programmed to use **zero**, **one**, **two**, or **three** boot mode select pins as needed.

BMSP configuration and boot definition table is either read from SECCFG or the SSU registers based on debugger connection status as explained:

- If debugger is connected, then emulation boot flow is followed, where following SSU registers are used to determine GPIO to be used :
 - EMU_BOOTPIN_CONFIG
 - EMU_BOOTDEF_LOW
 - EMU_BOOTDEF_HIGH
- If debugger is not connected, then the following SECCFG locations are used to determine the boot modes:
 - BOOTPIN_CONFIG
 - BOOTDEF_LOW
 - BOOTDEF_HIGH

Note

Configuration of SECCFG locations for boot settings is enabled through the Sysconfig tool - System Security module. It is recommended to use the Sysconfig tool for configuring SECCFG.

Table 3-7. BOOTPIN-CONFIG Bit Fields

Bit	Name	Description
31:24	Key	Write 0x5A to these 8-bits to indicate to the boot ROM code that the bits in this register are valid.
23:16	Boot Mode Select Pin 2 (BMSP2)	Refer to BMSP0 description.
15:8	Boot Mode Select Pin 1 (BMSP1)	Refer to BMSP0 description.
7:0	Boot Mode Select Pin 0 (BMSP0)	Set to the GPIO pin to be used during boot (GPIO0 up to GPIO254). 0x0 = GPIO0 0x01 = GPIO1, and so on. Writing 0xFF disables this BMSP and this pin is no longer used to select the boot mode.

Note

GPIO that can be either digital and analog type pins, digital type inputs are possible on these pins provided the software writes to the GPIOHAMSEL register bits.

The following GPIOs that are not available on any package cannot be used as a boot mode select pin. If selected for a particular BMSP, the boot ROM automatically selects the factory default GPIOs for BMSP0 and BMSP1. Factory default for BMSP2 is 0xFF, which disables the BMSP.

Table 3-8. Standalone Boot Mode Select Pin Decoding

BOOTPIN_CONFIG Key	BMSP0	BMSP1	BMSP2	Realized Boot Mode
!= 0x5A	Don't Care	Don't Care	Don't Care	Boot as defined by the factory default BMSPs.
= 0x5A	0xFF	0xFF	0xFF	Boot as defined in the boot table for boot mode 0 (All BMSPs disabled).
	Valid GPIO	0xFF	0xFF	Boot as defined by the value of BMSP0 (BMSP1 and BMSP2 disabled).
	0xFF	Valid GPIO	0xFF	Boot as defined by the value of BMSP1 (BMSP0 and BMSP2 disabled).
	0xFF	0xFF	Valid GPIO	Boot as defined by the value of BMSP2 (BMSP0 and BMSP1 disabled).
	Valid GPIO	Valid GPIO	0xFF	Boot as defined by the values of BMSP0 and BMSP1 (BMSP2 disabled).
	Valid GPIO	0xFF	Valid GPIO	Boot as defined by the values of BMSP0 and BMSP2 (BMSP1 disabled).
	0xFF	Valid GPIO	Valid GPIO	Boot as defined by the values of BMSP1 and BMSP2 (BMSP0 disabled).
	Valid GPIO	Valid GPIO	Valid GPIO	Boot as defined by the values of BMSP0, BMSP1, and BMSP2.
	Invalid GPIO	Valid GPIO	Valid GPIO	BMSP0 is reset to the factory default BMSP0 GPIO. Boot as defined by the values of BMSP0, BMSP1, and BMSP2.
	Valid GPIO	Invalid GPIO	Valid GPIO	BMSP1 is reset to the factory default BMSP1 GPIO. Boot as defined by the values of BMSP0, BMSP1, and BMSP2.
	Valid GPIO	Valid GPIO	Invalid GPIO	BMSP2 is reset to the factory default state, which is disabled. Boot as defined by the values of BMSP0 and BMSP1.

Note

When decoding the boot mode, BMSP0 is the least-significant bit and BMSP2 is the most-significant bit of the boot table index value. It is recommended when disabling BMSPs to start with disabling BMSP2. For example, in an instance when only using BMSP2 (BMSP1 and BMSP0 are disabled), then only the boot table indexes of 0 and 4 are selectable. In the instance when using only BMSP0, then the selectable boot table indexes are 0 and 1.

3.4.2 Configuring Boot Mode Table Options

This section explains how to configure the boot definition table, BOOTDEF, for the device and the associated boot options (refer to [Table 3-9](#)). The 64-bit location is located in user-configurable SECCFG locations in the BOOTDEF_LOW and BOOTDEF_HIGH locations. When debugging, EMU_BOOTDEF_LOW and EMU_BOOTDEF_HIGH are the emulation equivalents of BOOTDEF_LOW and BOOTDEF_HIGH, and can be programmed to experiment with different boot mode options without writing to SECCFG locations.

The range of customization to the boot definition table depends on how many boot mode select pins (BMSP) are being used. For example, 0 BMSPs equals to 1 table entry, 1 BMSP equals to 2 table entries, 2 BMSPs equals to 4 table entries, and 3 BMSPs equals to 8 table entries. Refer to [Section 3.4.3](#) for examples on how to setup the BOOTPIN_CONFIG and BOOTDEF values.

Table 3-9. BOOTDEF Bit Fields

BOOTDEF Name	Byte Position	Name	Description
BOOT_DEF0	7:0	[3:0] BOOT_DEF0 Mode	Set the boot mode number from Section 3.3.2 . Any unsupported boot mode causes the device to either go to wait boot (debugger connected) or boot to Flash (standalone).
		[7:4] BOOT_DEF0 Options	Set alternate/additional boot options. This can include changing the GPIOs for a particular boot peripheral or specifying a different Flash entry point. Refer to Section 3.7.9 for valid BOOTDEF values to set in the table.
BOOT_DEF1	15:8	BOOT_DEF1 Mode/Options	Refer to BOOT_DEF0 description.
BOOT_DEF2	23:16	BOOT_DEF2 Mode/Options	
BOOT_DEF3	31:24	BOOT_DEF3 Mode/Options	
BOOT_DEF4	39:32	BOOT_DEF4 Mode/Options	
BOOT_DEF5	47:40	BOOT_DEF5 Mode/Options	
BOOT_DEF6	55:48	BOOT_DEF6 Mode/Options	
BOOT_DEF7	63:56	BOOT_DEF7 Mode/Options	

3.4.3 Boot Mode Example Use Cases

This section demonstrates some use cases for configuring the boot mode select pins and boot modes.

3.4.3.1 Zero Boot Mode Select Pins

This use-case demonstrates a scenario for an application that does not use any boot mode select pins and always has the device boot to Flash.

1. Program the BOOTPIN_CONFIG location in SECCFG as follows:
 - Set BOOTPIN_CONFIG.BMSP0 to 0xFF
 - Set BOOTPIN_CONFIG.BMSP1 to 0xFF
 - Set BOOTPIN_CONFIG.BMSP2 to 0xFF
 - Set BOOTPIN_CONFIG.KEY to 0x5A for boot ROM to treat these register bits as valid and use the custom boot table.
2. Program the SECCFG BOOTDEF location options for the device. This essentially sets up a device-specific boot mode table. Refer to [Section 3.7.9](#) for valid BOOTDEF values to set in the table.
 - Set BOOTDEF.BOOTDEF0 to 0x03 for booting to Flash (entry address option 0). This sets Flash boot to boot table index 0.
 - Refer to [Section 3.7.2](#) for the available Flash entry points.

Table 3-10. Zero Boot Pin Boot Table Result

Boot Mode Table Number	Boot Mode
0	Flash Boot (0x03)

3.4.3.2 One Boot Mode Select Pin

This use-case demonstrates a scenario for an application using one boot mode select pin to select between booting to Flash or using CAN boot.

1. Program the BOOTPIN_CONFIG location in SECCFG as follows:
 - Set BOOTPIN_CONFIG.BMSP0 to a user specified GPIO, such as 0x0 for GPIO0
 - Set BOOTPIN_CONFIG.BMSP1 to 0xFF
 - Set BOOTPIN_CONFIG.BMSP2 to 0xFF
 - Set BOOTPIN_CONFIG.KEY to 0x5A for boot ROM to treat these register bits as valid and use the custom boot table.
2. Program the SECCFG - BOOTDEF location options for the device. This essentially sets up a device-specific boot mode table. Refer to [Section 3.7.9](#) for valid BOOTDEF values to set in the table.
 - Set BOOTDEF.BOOTDEF0 to 0x02 for CAN booting. This sets CAN boot to boot table index 0.
 - Set BOOTDEF.BOOTDEF1 to 0x03 for booting to Flash (entry address option 0). This sets Flash boot to boot table index 1.

Table 3-11. One Boot Pin Boot Table Result

Boot Mode Table Number	Boot Mode
0	CAN Boot (0x02)
1	Flash Boot (0x03)

3.4.3.3 Three Boot Mode Select Pins

This use-case demonstrates a scenario for an application using three boot mode select pins to select between various boot modes in the custom boot table.

1. Program the BOOTPIN_CONFIG location in SECCFG as follows:
 - Set BOOTPIN_CONFIG.BMSP0 to a user specified GPIO, such as 0x0 for GPIO0
 - Set BOOTPIN_CONFIG.BMSP1 to a user specified GPIO, such as 0x1 for GPIO1
 - Set BOOTPIN_CONFIG.BMSP2 to a user specified GPIO, such as 0x2 for GPIO2
 - Set BOOTPIN_CONFIG.KEY to 0x5A for boot ROM to treat these register bits as valid and use the custom boot table.
2. Program the SECCFG BOOTDEF location options for the device. This essentially sets up a device-specific boot mode table. Refer to [Section 3.7.9](#) for valid BOOTDEF values to set in the table.
 - Set BOOTDEF.BOOTDEF0 to 0x02 for CAN booting. This sets CAN boot to boot table index 0.
 - Set BOOTDEF.BOOTDEF1 to 0x03 for booting to Flash. This sets Flash boot to boot table index 1.
 - Set BOOTDEF.BOOTDEF2 to 0x01 for booting to UART booting. This sets UART boot to boot table index 2.
 - Set BOOTDEF.BOOTDEF3 to 0x66 for SPI booting (alternate GPIO option 3). This sets SPI boot to boot table index 3.
 - Set BOOTDEF.BOOTDEF4 to 0x05 for booting to RAM. This sets RAM boot to boot table index 4.

Table 3-12. Three Boot Pins Boot Table Result

Boot Mode Table Number	Boot Mode
0	CAN Boot (0x02)
1	Flash Boot (0x03)
2	UART Boot (0x01)
3	SPI - Alt3 (0x66)
4	RAM Boot (0x05)
5, 6, 7	Not used in this example

3.5 Device Boot Flow Diagrams

This section details the C29x CPU boot flow diagrams for standalone and emulation boot flows.

3.5.1 Device Boot Flow

The following flow diagrams describe how the device boots up after PORESETn. HSM starts up first and then releases reset to CPU1. Detailed CPU1 boot flow is explained in later sections and for detailed HSM boot flow, refer to [F29H85x Security Software and Documentation](#).

The device boot flow follows below steps and interactions between HSM and C29 CPU1 boot flows highlighted below :

1. HSM Core boots up after power on with HSM WDT enabled with 300ms timeout
 - a. HSM ROM starts running and releases the C29x CPU1 (Main application core) out of reset
 - b. C29x CPU1 comes out of reset and C29x CPU1 ROM starts executing
2. HSM Core sends un halt command to C29 CPU1 ROM
 - a. C29x CPU1 ROM code keeps waiting for un halt command from HSM ROM
 - b. Before the step 2, HSM core ROM finishes executing the power on self-tests (if enabled in SECCFG), device PLL configuration, HSM and security manager configuration and SSU authentication (only in HSSE device type)
3. After un halt request is received C29x CPU1 core starts hardware initialization (refer to CPU1 detailed boot flow) with C29 Watchdog enabled (419msec timeout) and reads device ID from HSM mailbox
4. C29x CPU1 ROM proceeds to decode boot mode and disables C29x watchdog just before jumping to link1 bootloader execution
 - a. Boot mode signature decoded by C29x CPU1 ROM is shared with HSM ROM. HSM ROM waits for valid bootmode signature from C29x CPU ROM without timeout
5. C29x CPU jumps to link1 bootloader execution and sends HELLO message to HSM over IPC
 - a. HSM waits for the HELLO message from C29x CPU1 to begin authentication, timeout for wait is 100 seconds software based timeout
 - b. HSM enables HSM WDT with 180 seconds timeout after HELLO is received or on timeout waiting for message
6. HSM authenticates C29 application SBL and certificate verification based on device type
 - a. CERT and image authentication is done with HSM WDT enabled for 180 seconds timeout
 - b. Based on the authentication result C29x CPU1 jumps to application if successful or wait boot otherwise
7. HSMRT (HSM Runtime) authentication is performed by HSM rom code with HSM WDT enabled with 180 seconds, if successfully authenticated HSM core jumps to HSMRT application with HSM WDT disabled.

Figure 3-1. F29x device boot flow high level

3.5.2 CPU1 Boot Flow

Upon reset, CPU1 follows the boot flow shown in [Figure 3-2](#). Depending on whether a JTAG debugger is connected to the device, the CPU1 either continues booting following the emulation boot flow or the standalone boot flow.

Note

Boot on reset (BOR) follows same flow as power on reset (POR).

Figure 3-2. Device Boot Flow from Reset to System Boot

Figure 3-3. System Boot Flow to Application Code

3.5.3 Emulation Boot Flow

Figure 3-4 shows the emulation boot flow when JTAG debugger is connected and if emulation boot is enabled.

3.5.4 Standalone Boot Flow

Figure 3-5 shows the standalone boot flow for CPU1 when no JTAG debugger is connected to the device.

Figure 3-4. Emulation Boot Flow

Figure 3-5. Standalone Boot Flow

3.6 Device Reset and Exception Handling

3.6.1 Reset Causes and Handling

[Table 3-13](#) explains the actions each boot ROM performs upon reset for a specific reset cause. The boot ROM flow only explicitly checks for POR and XRS reset cause flags.

Table 3-13. Boot ROM Reset Causes and Actions

Reset Source	CPU1 Boot ROM Action
Power on Reset (POR)	1. Default boot flow 2. RAM initialization 3. Execute LPOST/MPOST if enabled
External Reset (XRS) Includes: • CPU1 Watchdog Reset • NMI Watchdog Reset (Issued by ESM) • SIMRESET XRSn • ESM Critical Priority Output (ESMCPUxCRITICAL,ESMRESET) • ECAT RESET	Default boot flow
CPU1 SYSRSn (Debugger Reset)	See Figure 3-3

3.6.2 Exceptions and Interrupts Handling

[Table 3-14](#) explains the actions that the boot ROM performs, if any exceptions occur during boot. The philosophy of boot ROM is to try and start the application and log the error.

The boot ROM sets up the default NMI handlers and enables NMI on every reset type. When NMI is triggered on any of the Group0 error event input to CPU1 ESM, the error status pin is driven LOW. The interval for which the error pin remains LOW is determined by the count programmed into SYSTEM ESM instance PIN_CNTR_PRE register. The error status pin GPIO number is read from the SECCFG and configured as error status pin

Table 3-14. Boot ROM Exceptions and Actions

Link	Exception Event Source	CPU1 Boot ROM Action	Event Logged
LINK0 and LINK1	NMI - Uncorrectable ECC Errors	Reset the device - Forced immediate reset	Yes
LINK0 and LINK1	NMI - Other than Uncorrectable ECC Errors	Enable C29x Watchdog (Timeout - 6.7 seconds) and Jump to Link1 enter Wait Boot	Yes
LINK0	Critical Trim Loading	Reset the device - Forced immediate reset	Yes
LINK0	LINK0 SSU APR - Failure to acquire APR's for LINK0 execution	Enable C29x Watchdog (Timeout - 6.7 seconds) and Jump to Link1 enter Wait Boot	Yes
LINK0	CPU1 valid SECCFG CRC check mismatch	Enable C29x Watchdog (Timeout - 6.7 seconds) and Jump to Link1 enter Wait Boot	Yes
LINK0	Error during SSU configuration, SSU self test or SSU APR configurations	Enable C29x Watchdog (Timeout - 6.7 seconds) and Jump to Link1 enter Wait Boot	Yes
LINK1	Error during Certificate parsing	Enter Wait Boot	Yes
LINK1	HSM authentication result is "RETRY"	Enter Wait Boot	Yes
LINK0	SYNCBUSY polling timeout	Enter Wait Boot	Yes

#	Description	Error ID	Status Set	Final Action Taken
Trim (Critical and Non-Critical)				

#	Description	Error ID	Status Set	Final Action Taken
1	Trim CRC verification failed	N/A	bromStatus.criticaltrim = STATUS_FAIL	Reset the device (forced immediate reset)
2	Critical trim loading failed (Flash, APLL, Oscillator, or PMM trim timeout/readback error)	N/A	bromStatus.criticaltrim = STATUS_FAIL	Reset the device (forced immediate reset)
3	Non-critical trim readback verification failed	N/A	bromStatus	Continue boot (status recorded)
SSU Configuration				
4	SSU Power-On Self Test failed — register readback CRC mismatch (PORESETn reset only)	N/A	bromStatus.ssuPost = STATUS_FAIL	Continue boot (status recorded)
5	SSU configuration failed (BANKMGMT, SECCFG, BANKMODE, SSUMODE, or register write error)	LINK0_ERR_ID_SSU_CO NFIG (0x57DE827C)	bromStatus.ssuInit = STATUS_FAIL	Enable C29x Watchdog (6.7s timeout), enter Wait Boot
SSU Configuration Failure - Detailed Sub-Errors				
6	No valid Bank Management sector found for CPU1	N/A	ssuStatus.bankMgmtCpu1 = STATUS_FAIL	Enable C29x Watchdog (6.7s timeout), enter Wait Boot
7	No valid Bank Management sector found for CPU3	N/A	ssuStatus.bankMgmtCpu3 = STATUS_FAIL	Enable C29x Watchdog (6.7s timeout), enter Wait Boot
8	BANKMODE value invalid	N/A	ssuStatus.getBankMode = STATUS_FAIL	Enable C29x Watchdog (6.7s timeout), enter Wait Boot
9	SSUMODE value invalid	N/A	ssuStatus.getSsuMode = STATUS_FAIL	Enable C29x Watchdog (6.7s timeout), enter Wait Boot
10	No valid SECCFG sector found for CPU1	N/A	ssuStatus.secCfgCpu1 = STATUS_FAIL	Enable C29x Watchdog (6.7s timeout), enter Wait Boot
11	No valid SECCFG sector found for CPU3	N/A	ssuStatus.secCfgCpu3 = STATUS_FAIL	Enable C29x Watchdog (6.7s timeout), enter Wait Boot
12	SECCFG sector CRC mismatch (computed CRC differs from stored CRC in SECCFG)	N/A	bromStatus.ssuInit = STATUS_FAIL	Enable C29x Watchdog (6.7s timeout), enter Wait Boot
13	SSU configuration register double-read verification failed	N/A	ssuStatus.readError = STATUS_FAIL	Enable C29x Watchdog (6.7s timeout), enter Wait Boot
APR Configuration				
14	Access Protection Region (APR) configuration failed for LINK0 peripherals	LINK0_ERR_ID_APR_CO NFIG (0x2AC69B4F)	bootMode = 0xFF (ERROR_BOOT)	Enable C29x Watchdog (6.7s timeout), enter Wait Boot
15	SECCFG APR configuration readback verification failed	LINK0_ERR_ID_SECCFG _APR (0x69D473BE)	ssuStatus.aprCfg = STATUS_FAIL	Enable C29x Watchdog (6.7s timeout), enter Wait Boot
NMI Handler				
16	NMI - Uncorrectable ECC Errors	LINK0_ERR_ID_NMI (0xCDF5847D)	nmiStatus	Reset the device (NMI Watchdog reset)
17	NMI - Other than Uncorrectable ECC Errors	LINK0_ERR_ID_NMI (0xCDF5847D)	nmiStatus	Enable C29x Watchdog (6.7s timeout), enter Wait Boot
18	NMI handler cannot access Error Aggregator registers (APR configuration failed)	N/A	None (cannot access status RAM)	Reset the device (NMI Watchdog timeout)
Clock Configuration				

#	Description	Error ID	Status Set	Final Action Taken
19	External crystal (XTAL) synchronization timed out	LINK0_ERR_ID_XTAL_SY NCBUSY (0x9BC4EA4C)	bootMode = 0xFF (ERROR_BOOT)	Enter Wait Boot
20	SYSCLK configuration SYNCBUSY timeout (SYNCBUSY bit did not clear)	N/A	None (no error status recorded)	Enter Wait Boot
21	System PLL failed to achieve lock	N/A	None (no error status recorded)	Continue boot (PLL bypassed, dividers not configured)
Miscellaneous (RAM Init, Watchdog Sync)				
22	RAM initialization did not complete within timeout	N/A	bromStatus.ramInit = STATUS_FAIL	Continue boot (status recorded)
23	Watchdog synchronization busy bit did not clear within timeout	LINK0_ERR_ID_WDG_SY NCBUSY (0xFE3BC723)	bootMode = 0xFF (ERROR_BOOT)	Enter Wait Boot
Boot Mode Selection				
24	Unsupported emulation boot mode decoded	N/A	bootMode = WAIT_BOOT	Fallback to WAIT_BOOT
25	Unsupported standalone boot mode decoded	N/A	bootMode = FLASH_BOOT	Fallback to FLASH_BOOT
26	HSM recovery with non-RAM boot mode, forced to WAIT boot	N/A	bootMode = WAIT_BOOT	Enter Wait Boot
27	Application flash appears unprogrammed (certificate and image start words are 0xFFFFFFFF)	N/A	bootMode = WAIT_BOOT	Enter Wait Boot
Bootloader (Peripheral Initialization)				
28	I2C peripheral initialization failed	N/A	None (no error status recorded)	Enter Wait Boot
29	SPI peripheral initialization failed	N/A	None (no error status recorded)	Enter Wait Boot
30	External crystal powerup timed out before MCAN initialization	N/A	None (no error status recorded)	Continue boot (PLL configured with INTOSC2 as reference)
31	MCAN message reception timed out	N/A	None (no error status recorded)	Enter Wait Boot
32	MCAN controller configuration failed	N/A	None (no error status recorded)	Enter Wait Boot
Secure Boot (IPC / HSM)				
33	IPC HELLO handshake with HSM failed	N/A	bootloadStatus (helloMsg=FAIL)	Enter Wait Boot
34	Certificate read failed or certificate exceeds maximum size (4 KB)	N/A	bootloadStatus (readCert=FAIL)	Enter Wait Boot
35	Failed to send certificate to HSM via IPC	N/A	bootloadStatus (certMsg=FAIL)	Enter Wait Boot
36	Application image size invalid (zero or exceeds available memory)	N/A	bootloadStatus (getImageSize=FAIL)	Enter Wait Boot
37	Failed to read image data block from boot peripheral	N/A	bootloadStatus (readBlockErr=FAIL)	Enter Wait Boot
38	Timeout sending image blocks to HSM via IPC	N/A	bootloadStatus (sendBlockSkipErr=FAIL)	Enter Wait Boot
39	Failed to receive authentication result from HSM	N/A	bootloadStatus (resMsg=FAIL)	Enter Wait Boot
40	Failed to send result acknowledgment to HSM	N/A	bootloadStatus (resAck=FAIL)	Continue to application (status recorded)
41	HSM reported authentication or processing failure	N/A	bootloadStatus (bootResult = HSM result code, resMsg=PASS)	Enter Wait Boot

#	Description	Error ID	Status Set	Final Action Taken
42	HSM did not acknowledge cancel message	N/A	bootloadStatus (ackRcvErr=FAIL)	Enter Wait Boot
43	Failed to send cancel message to HSM	N/A	bootloadStatus (cancelMsgErr=FAIL)	Enter Wait Boot
44	IPC communication failure (timeout, message type mismatch, or checksum error)	N/A	bootloadStatus (field depends on which secure boot step is active)	Enter Wait Boot
Certificate Parsing				
45	Certificate does not start with valid DER SEQUENCE tag	N/A	bootloadStatus (readCert=FAIL)	Enter Wait Boot
46	DER field value length exceeds remaining certificate data (malformed TLV encoding)	N/A	bootloadStatus (getImageSize=FAIL)	Enter Wait Boot
47	Boot info extension fields missing or malformed (cert_type, boot_core, load_addr, or image_size)	N/A	bootloadStatus (getImageSize=FAIL)	Enter Wait Boot

3.7 Boot ROM Description

This section explains the details regarding the device boot ROMs.

3.7.1 Boot ROM Configuration Registers

The boot ROM code involves several memory addresses and registers used during execution. There are two sets of configurations : one for emulation and one for standalone boot flow. The emulation locations located in SSU registers - SSU_GEN_REGS, SSU_CPU1_CFG_REGS, SSU_CPU2_CFG_REGS and SSU_CPU3_CFG_REGS emulate the SECCFG configurations and can be written to as many times as needed. The user configurable SECCFG locations can also be used in the standalone boot flow to program the device boot mode definitions. [Table 3-15](#) details these locations. For bit field configuration details of BOOTPIN_CONFIG and BOOTDEF, see [Section 3.4.1](#) and [Section 3.4.2](#), respectively.

The SSU based EMU boot registers for emulation boot flow are reset on XRSn. SECCFG can be reprogrammed multiple times; hence, the SECCFG based standalone boot mode can be used instead if XRSn assertion is required in case of peripheral boot modes.

Note

SECCFG must be programmed carefully. The device boot ROM verifies the contents of the active CPU1 SECCFG sector using a CRC32 algorithm before loading the settings stored in the SECCFG sector into the SSU registers. If the CRC check fails, the boot process is aborted.

Table 3-15. Boot ROM Registers

Boot Flow	SSU Register Name	SECCFG Name	Register Address	SECCFG Address
Emulation	EMU_BOOTPIN_CONFIG		0x3008_0030	-
	EMU_BOOTDEF_LOW		0x3008_1028	-
	EMU_BOOTDEF_HIGH		0x3008_102C	-
Standalone		BOOTPIN_CONFIG	-	0x10D8_17A8
		BOOTDEF_LOW	-	0x10D8_17C8
		BOOTDEF_HIGH	-	0x10D8_17CC

3.7.1.1 MPOST and LPOST Configurations

Using Sysconfig-System Security tab, the users can load the appropriate settings for MPOST and LPOST executions as needed.

3.7.2 Entry Points

This sections gives details about the entry point addresses for various boot modes. These entry points direct the boot ROM what address to branch to at the end of booting as per the selected boot mode.

[Table 3-16](#) gives details about the entry point addresses for the Flash boot mode and RAM boot mode.

Table 3-16. Entry Point Addresses for CPU1

Boot Mode	Option	BOOTDEFx Value	Flash Read Port	Address	Packages Supported
Flash	0	0x03	FRI1 RP0	0x1000_1000	All
RAM	0	0x05	N/A	0x2010_0000 (LPA0 SRAM)	All
RAM	1	0x25	N/A	0x2011_0000 (CPA0 SRAM)	All

3.7.3 Wait Points

The wait mode puts the CPU in a loop in the boot ROM code and does not branch to the user application code. The device can enter the wait boot mode either through manually being set or because of some issue during boot up. Using the wait boot mode is recommended when using a debugger to avoid any JTAG issues. There is an infinite for loop when entered in wait boot so user can easily halt CPU and load code when connected using debugger.

Table 3-17. Wait Boot Options

Option	BOOTDEFx Value	Watchdog Status	Package Supported
0 (default)	0x04	Disabled	All

During boot ROM execution, there are situations where the CPU can enter a wait loop in the code. This state can occur for a variety of reasons.

[Table 3-18](#) details the address ranges that the CPU PC register value reaches to if the CPU has entered one of these instances.

Following are the actions for entering wait boot mode:

- Wait boot is set by the user as the boot mode.
- Boot mode is unrecognizable and a debugger is connected to the device.
- An error occurs during emulation boot and the boot mode pins are decoded with a value not recognized as a valid boot mode.

Table 3-18. Wait Point Addresses

Program Counter Address Range (Rev A)	Program Counter Address Range (Rev C)	Description
0x1535C	0x1549C	In Wait Boot mode
0x14EB0	0x15040	In Wait Boot mode

3.7.4 Memory Maps

3.7.4.1 Boot ROM Memory-Maps

[Table 3-19](#) details the ROM memory-map including Link0 and Link1 ROM.

Table 3-19. Boot ROM Memory-Map

Memory	Start Address	Length
Reset Vector	0x0000_0000	0x0040
NMI Vector	0x0000_0040	0x0040
Default Handlers	0x0000_0080	0x0F80
User Data Tables	0x0000_1000	0x7000
Link0 Boot code	0x0000_8000	0x8000
Link1 Boot code	0x0001_0000	0xFFFF

3.7.4.2 Reserved RAM Memory-Maps

Table 3-20 details memory usage in RAM that is reserved for boot ROM to use. These memory sections can be reserved in the user application.

Table 3-20. Reserved RAM Memory-Map

Memory	Description	Origin Address	Length
M0 RAM	Link0 Stack	0x2000_0000	0x800
M0 RAM	Boot ROM Status	0x2000_0800	0x170
M0 RAM	Link0 Data Sections	0x2000_0970	0x5C0
M0 RAM	Non Critical TRIM's	0x2000_0F30	0xCF

3.7.5 BootROM SSU APRs

This section highlights the peripherals that need appropriate access protection ranges enabled for the SSU module to provide appropriate permissions for Link0/Link1 Bootrom code to properly boot up the device.

For Link0, execution following APRs if configured by the user must be of the correct size and permissions for bootrom to execute correctly (see Table 3-21).

Table 3-21. Link0 APR Permissions

Peripheral Region	Base Address	Size
CPUPERCFG_BASE	0x3020_8000	0x1000
CPUSYS_BASE	0x3020_0000	0x1000
GPIODATA_BASE	0x3026_8000	0x1000
ADCA_BASE	0x700A_0000	0x5000
DACA_BASE	0x700D_0000	0x2000
CDA0_RAM_BASE	0x2012_0000	0x4000
ERRORAGGREGATOR_BASE	0x6008_C000	0x1000
ESMCPU1_BASE	0x6009_0000	0x1000
ESMSYSTEM_BASE	0x6009_F000	0x1000
HSM_MAILBOX_BASE_ADDR_RX	0x302C_1000	0x1000

For Link1, execution following APRs needs to be configured by the user for the correct size and permissions for bootrom to execute correctly (see Table 3-22).

Table 3-22. Link1 APR Permissions

Boot Mode	Region	APR Start	APR End	APR Access	Description
ALL	CPU1IPCSND_BASE	0x3022_0000	0x3022_7FFF	0x0000_000C - R/W	IPC registers
ALL	Mail box	0x302C_0000	0x302C_1FFF	0x0000_000C - R/W	HSM mailbox for IPC
FLASH	FLASH FRI_1_RP0	0x1000_0000	0x1000_0FFF	0x0000_0004 - R	Read access for first 4KB of Flash for certificate parsing
I2C, SPI, UART, MCAN	CPUPERCFG_BASE	0x3020_8000	0x3020_8FFF	0x0000_000C - R/W	Peripheral clock enable and reset
PARALLEL, I2C, SPI, UART, MCAN	GPIODATA_BASE	0x3026_8000	0x3026_8FFF	0x0000_000C - R/W	GPIO configuration registers
I2C	I2CA_BASE	0x7015_0000	0x7015_0FFF	0x0000_000C - R/W	I2C registers
SPI	SPIA_BASE	0x7015_8000	0x7015_8FFF	0x0000_000C - R/W	SPI registers
UART	UARTA_BASE	0x6007_0000	0x6007_1FFF	0x0000_000C - R/W	UART registers
MCAN	MCANA_DRIVER_BASE	0x6002_0000	0x6002_4FFF	0x0000_000C	MCAN registers
MCAN	DCC1_BASE	0x6008_0000	0x6008_0FFF	0x0000_000C - R/W	DCC1 register

3.7.6 LINK1 RAMOPEN

Link1 RAMOPEN covers the following memories :

1. LPA0-1
2. LDA0-7

Refer to the SSU Chapter for more detailed description of the RAMOPEN feature functionality. Link1 RAMOPEN enable clears the RAM content using the RAMINIT functionality. After the intended use for RAMOPEN completes, return the RAM back to the user application by writing 1 to the RAMOPENCLR.CLEAR_LINK1 register, Link1 wipe on clear enable clears RAM contents while exiting the RAMOPEN mode.

Table 3-23. LINK1 RAMOPEN on reset scenarios for HSFS device

Boot Mode	Reset Type	EMU_BOOTEN	Link1 RAMOPEN enable	Link1 RAMOPEN Wipe on Clear Enable
Flash	All	NA	True	False
Flash	CPU1.SYSRSn (Debugger connected and SYSRSN_KEY = 0xA1B2C3D4)	NA	False	False
RAM	All	Disabled	True	False
RAM	All	Enabled	False	NA
WAIT	All	NA	False	NA
PARALLEL I2C SPI UART MCAN	All	NA	True	True

3.7.7 ROM Structure and Status Information

[Table 3-24](#) details the boot ROM structure that can be integrated into an application to use the available ROM code status information and tables.

Table 3-24. ROM Symbol Tables

ROM Structure	Library Name	Location
ROM Code Status Information	driverlib	Under <i>source/driverlib/bootrom.c</i> and <i>bootrom.h</i> in F29-SDK
Twiddle Tables	driverlib	

3.7.8 Boot Modes and Loaders

The available boot modes and bootloaders supported on this device are detailed in this section.

3.7.8.1 Boot Modes

This section details the available boot modes that do not involve a peripheral boot loader. [Table 3-25](#) details the available boot modes that do not involve a peripheral boot loader.

Table 3-25. Boot Mode Availability

Boot Mode	CPU Support
Flash Boot	C29x CPU
RAM Boot	C29x CPU
Wait Boot	C29x CPU

3.7.8.1.1 Flash Boot

Flash boot mode branches to the configured memory address in Flash. Refer to [Section 3.7.2](#) for all the available Flash address options.

3.7.8.1.2 RAM Boot

RAM boot mode branches to the configured memory address in RAM. Refer to [Section 3.7.2](#) for all the available RAM address options.

3.7.8.1.3 Wait Boot

Wait boot mode branches to the memory address as mentioned in [Section 3.7.3](#).

3.7.8.2 Bootloaders

This section details the available boot modes that use a peripheral boot loader.

3.7.8.2.1 SPI Boot Mode

The SPI loader expects an SPI-compatible 16-bit or 24-bit addressable serial EEPROM or serial Flash device to be present on the SPI-A pins as shown in [Figure 3-6](#). The SPI bootloader supports an 8-bit data stream and does not support a 16-bit data stream.

Figure 3-6. Overview of SPI Bootloader Operation

The SPI boot ROM loader initializes the SPI module to interface to a serial SPI EEPROM or Flash. Devices of this type include, but are not limited to, the Xicor X25320 (4Kx8) and Xicor X25256 (32Kx8) SPI serial SPI EEPROMs and the Atmel AT25F1024A serial Flash.

The SPI boot ROM loader initializes the SPI with the following settings: FIFO enabled, 8-bit character length, internal SPICLK controller mode and talk mode, transfer protocol : Mode 1 - rising edge with phase delay, clock phase = 1, polarity = 0 and using 2 Mbps baud rate.

If the download is to be performed from an SPI port on another device, then that device must be set up to operate in the peripheral mode and mimic a serial SPI EEPROM. Immediately after entering the SPI_Boot function, the pin functions for the SPI pins are set to primary and the SPI is initialized.

3.7.8.2.2 I2C Boot Mode

The I2C bootloader expects an 8-bit wide I2C-compatible EEPROM device to be present at address 0x50 on the I2C-A bus as shown in Figure 3-7. The EEPROM must adhere to conventional I2C EEPROM protocol, as described in this section, with a 16-bit base address architecture.

Figure 3-7. EEPROM Device at Address 0x50

If the download is to be performed from a device other than an EEPROM, then that device must be set up to operate in the target mode and mimic the I2C EEPROM. Immediately after entering the I2C boot function, the GPIO pins are configured for I2C-A operation and the I2C is initialized. The following requirements must be met when booting from the I2C module:

- The input frequency to the device must be in the appropriate range.
- The EEPROM must be at target address 0x50.

The bit-period prescalers (I2CCLKH and I2CCLKL) are configured by the bootloader to run the I2C at a 50 percent duty cycle at 100kHz bit rate (standard I2C mode) when the system clock is 10MHz.

Arbitration, bus busy, and target signals are not checked. Therefore, no other controller is allowed to control the bus during this initialization phase. If the application requires another controller during I2C boot mode, that controller must be configured to hold off sending any I2C messages until the application software signals that the software is past the bootloader portion of initialization.

The non-acknowledgment bit is checked only during the first message sent to initialize the EEPROM base address. This is to make sure that an EEPROM is present at address 0x50 before continuing. If an EEPROM is not present, the non-acknowledgment bit is not checked during the address phase of the data read messages. If a non-acknowledgment is received during the data read messages, the I2C bus hangs.

3.7.8.2.3 Parallel Boot Mode

The parallel general-purpose I/O (GPIO) boot mode asynchronously transfers code from the host to C29x internal memory. Each value is 8-bits long and follows the same data flow as outlined in [Figure 3-8](#).

Figure 3-8. Overview of Parallel GPIO Bootloader Operation

The control subsystem communicates with the external host device by polling/driving the Host Control and C29x control lines. The handshake protocol shown in [Figure 3-9](#) must be used to successfully transfer each word using GPIO [D0:D7]. This protocol is very robust and allows for a slower or faster host to communicate with the controller subsystem.

Two consecutive 8-bit words are read to form a single 16-bit word. The least-significant byte (LSB) is read first followed by the most-significant byte (MSB). In this case, data is read from GPIO[D0:D7].

The device first signals the host that the device is ready to begin data transfer by pulling the C29x control pin low. The host load then initiates the data transfer by pulling the DSP control pin low. The complete handshake protocol is shown in [Figure 3-9](#).

Figure 3-9. Parallel GPIO Bootloader Handshake Protocol

1. The device indicates the device is ready to start receiving data by pulling the C29x control pin low.
2. The bootloader waits until the host puts data on GPIO [D0:D7]. The host signals to the device that data is ready by pulling the host control pin low.
3. The device reads the data and signals the host that the read is complete by pulling the C29x control pin high.
4. The bootloader waits until the host acknowledges the device by pulling the host control pin high.
5. The device again indicates the device is ready for more data by pulling the C29x control pin low.

This process is repeated for each data value to be sent.

[Figure 3-10](#) shows the transfer flow from the host side. The operating speed of the CPU and host are not critical in this mode as the host waits for the device and the device in turn waits for the host. In this manner, the protocol works with both a host running faster and a host running slower than the device.

Figure 3-10. Parallel GPIO Mode - Host Transfer Flow

3.7.8.2.4 CAN Boot Mode

The CAN bootloader asynchronously transfers code from CAN-A to internal memory as shown in [Figure 3-11](#). The host can be any CAN node. The communication is first done with 11-bit standard identifiers (with a MSGID of 0x1) using two bytes per data frame.

Note

MCAN and CAN boot can be used with an external oscillator with a 25MHz and 20MHz frequency.

Figure 3-11. Overview of CAN-A Bootloader Operation

The bit timing registers are programmed in such a way that a 100kbps bit rate is achieved with a 20MHz external oscillator, as shown in [Table 3-26](#).

Table 3-26. Bit-Rate Value for External Oscillators

OSCCLK	SYSCLK	Bit Rate
20MHz	200MHz	100kbps
25MHz	200MHz	100kbps

The bootROM configures and locks PLL at 200MHz and also configures CAN bit clock at 20MHz using XTAL oscillator as clock source if detected; otherwise, defaults to INTOSC2.

Note

The CAN boot loader uses XTAL as the bit clock source and INTOSC2 as the system clock source.

Mailbox 1 is programmed with a standard MSGID of 0x1 for bootloader communication. The CAN host transmits only two bytes at a time, LSB first and MSB next. For example, to transmit the word 0x08AA to the device, transmit AA first, followed by 08.

3.7.8.2.5 CAN-FD Boot Mode

The CAN-FD bootloader asynchronously transfers code from CAN-FD to internal memory and follows same bootloader execution flow as [Section 3.7.8.2.4](#). The host can be any CAN-FD node. The communication is first done with 11-bit standard identifiers (with a MSGID of 0x1) using two bytes per data frame. The CAN-FD bootloader uses a fixed 64-byte payload size and default bit rate of 1Mbps for nominal phase and 2Mbps for data phase.

Mailbox 1 is programmed with a standard MSGID of 0x1 for boot-loader communication. The program flow of the CAN-FD bootloader is identical to the CAN bootloader.

3.7.8.2.6 UART Boot Mode

The UART bootloader is a peripheral bootloader that receives data and program over the UARTA RX line.

After power-on, when the host is connected and the device is set in UART boot mode, the controller (MCU) sends the SOCID on the UART TX line. Host can start sending the actual image data once the SOCID is received. After each data transfer, the bootloader echo's back the 8-bit character received to the host. This allows the host to check that each character was received by the bootloader.

The SOCID is sent out to the host on every cold/warm reset. The SOCID is also copied to M0 RAM (at address 0x2000 0980), which is transmitted over the UART to the host.

The UART bootloader supports 1 stop bit, no parity and 8-bit character transfers at baud rate of 115200bps.

Figure 3-12. UART Boot Mode

3.7.9 GPIO Assignments

This section details the GPIOs and boot option values used for boot mode set in the BOOT_DEF memory location located at BOOTDEF_LOW and BOOTDEF_HIGH. Refer to [Section 3.4.2](#) on how to configure BOOT_DEFx. When selecting a boot mode option, make sure to verify that the necessary pins are available in the pin mux options for the specific device package being used.

Default boot mode GPIO pins:

- Boot mode pin 0 - GPIO84
- Boot mode pin 1 - GPIO72

Guidelines on boot pin selection:

- Avoid pins that have PWM functionality.
- Cannot be analog or USB pins.
- Boot mode select pins and default boot peripheral pins can be available on all packages.
- Avoid JTAG emulation pins and crystal pins.
- Boot mode select pins can be inputs.
- Pins cannot have PHY bootstrap functionality.

Table 3-27. Parallel Boot Options

Option	BOOTDEF Value	D0-D7 GPIO	C29x (DSP) Control GPIO	Host Control GPIO	Package Supported
0 (default)	0x00	D0 - GPIO0 D1 - GPIO1 D2 - GPIO2 D3 - GPIO3 D4 - GPIO4 D5 - GPIO10 D6 - GPIO11 D7 - GPIO12	GPIO15	GPIO16	All
1	0x20	D0 - GPIO17 D1 - GPIO18 D2 - GPIO22 D3 - GPIO23 D4 - GPIO25 D5 - GPIO26 D6 - GPIO29 D7 - GPIO30	GPIO4	GPIO5	All

3	0x68	GPIO234	GPIO65	144-QFP, 176-QFP, 256-BGA

3.7.10 HSM and C29x ROM Task Ownership and Interactions

HSM (M4) has the primary ownership of the device at boot up and performs the following tasks:

1. PLL Initialization and Lock.
2. Run MPOST based on input from SECCFG settings input by user.
3. Run LPOST based on input from SECCFG settings input by user.
4. IPC Initialization and C29x CPU1 reset release.
5. C29x Application Image authentication.
6. C29x SBL validation and integrity check.
7. HSMRT validation and integrity check.

C29x SBL (Secondary Bootloader) authentication process:

1. Initialize Boot Peripheral to receive the image.
2. Copies image from host and loads into LDA RAM.
3. After copying, C29x CPU sends IPC message to HSM.
4. HSM starts certificate validation and image integrity checks.
5. HSM sends ACK back to C29x CPU1 and copies image from LDA to LPA RAM in case image authentication succeeds.
6. If the image authentication fails, then HSM retries the process again for a maximum of 5 times.

HSMRT (HSM Realtime App) authentication process:

1. SBL downloads HSMRT from the peripheral bootloader chosen by user.
2. SBL copies HSMRT image at LDA RAM.
3. C29x CPU sends IPC message to HSM after copying image.
4. HSM protects LDA memory and starts certificate and image validation.
5. HSM branches to LDA and releases protection in case of successful validation.
6. In case of failure, send NACK message to C29x CPU1.

3.7.10.1 Application Authentication by HSM

The application image either present on Flash or downloaded to RAM by peripheral bootloader is authenticated by HSM.

In case of peripheral bootloader, the following procedure is followed:

1. The certificate is downloaded to LDA7 RAM (0x200E_0000).
2. The image is downloaded at an offset of maximum size of certificate (4KB) at 0x200E_1000.
3. HSM reads the certificate and image and authenticates the image.
4. If the image authentication succeeds, then the image is copied to LPA0 RAM (0x20100000).
5. Then LINK1 makes protected jump to LPA0 address and starts executing the image.

The HSM and C29x CPU image authentication process is also summarized in [Figure 3-13](#).

Table 3-33. Authentication Process Error Handling

Error	Handling
Authentication Failure	Retry for 5 times and if error still persists, then enter wait boot.

Figure 3-13. Image Authentication by HSM

3.7.11 Boot Status Information

Boot ROM keeps a record of the various actions and events that occur during boot ROM execution. The reason for this is because NMI and other exceptions are enabled by default in the device and must be handled accordingly. Boot ROM stores the boot status information in a RAM location so that the user application can read this boot status and take the necessary actions per application's needs to handle these events.

3.7.11.1 Booting Status

Boot ROM health and booting status for CPU1 is written to a 32-bit address in the respective M0 RAM. This status is cleared on a POR or XRS reset. The previous status is retained on any other reset. For example, clear the status before performing a debugger device reset to view the latest boot ROM actions reflected in the status.

Table 3-34. Boot Information Parameters Address

Parameter	Address	Description
Link 0 Start Cycle Count	0x2000_0800	64 bit Link0 Start Cycle Count
Link 0 End Cycle Count	0x2000_0808	64 bit Link0 End Cycle Count

4.7 Software.....	792
4.8 LCM Registers.....	792

4.1 Introduction

Hardware module integrity during run-time is a critical functional safety requirement. Hardware Redundancy implemented by the lockstep CPU architecture (two CPUs executing the same function and the output of the CPUs are continuously compared) is a proven method for achieving high diagnostic coverage for both permanent and transient faults. The Lockstep Comparator Module (LCM) is implemented to compare output from the CPU to detect permanent and transient faults.

4.1.1 Features

The LCM implements the following features:

- Pipelined architecture
- Redundant comparison
- Self-test capability
 - Match and mismatch test
 - Error forcing capability
- Temporal redundancy: The operation of the two modules is skewed by two cycles to address the issue of common cause failures like failure of clock, power, and so on. This makes sure of temporal redundancy.
- Spatial redundancy: In the lockstep architecture, module instances are redundantly instantiated and the outputs are compared. Redundant instantiation provides spatial redundancy.
- Non-delayed functional output path to provide non-delayed CPU execution for the system (while still having temporal redundancy).
- Register protection of critical memory mapped registers of the module, using a parity scheme.

4.1.2 Block Diagram

Figure 4-1 shows the LCM block diagram.

Figure 4-1. LCM Block Diagram

Note

The *Module* described in this block diagram can be either a CPU (for example, CPU1) or a peripheral (for example, RTDMA) depending on availability for the device.

4.1.3 Lockstep Compare Modules

The following modules are supported with Lockstep comparison feature in this device:

1. CPU1 in lockstep with CPU2
2. CPU1 PIPE in lockstep with CPU2 PIPE
3. RTDMA1 in lockstep with RTDMA2
4. CPU1 Timers (0, 1, and 2) in lockstep with CPU2 Timers (0, 1, and 2)
5. CPU1 ERAD and DLT in lockstep with CPU2 ERAD and DLT, respectively

DEV_CFG_REGS[LSSEN] register controls lockstep enable/disable for all the modules that are mentioned above, which means either all of them operate as lockstep or split-lock (operating as independent modules).

Table 4-1. Lockstep versus Split-Lock Configurations

Configuration Type	DEV_CFG_REGS[LSSEN] Default : 1	LCM_CONTROL_REGS[CMPEM] Default : 0
Lock-Step	1	1
Split-Lock (Modules operating independently)	0	Not Applicable

4.2 Enabling LCM Comparators

Note

The redundant module is automatically enabled at boot.

To enable the LCM comparators upon device startup or after reset, perform the following steps at the beginning of the user application code:

1. Lock the LSEN configuration using the following bit:
 - DEV_CFG_REGS[DEVCFGLOCK2.LSEN = 1]
2. Enable the comparator for the desired modules using the following bit:
 - LCM_REGS[LCM_CONTROL.CMPEN = 1]
 - Lockstep compare begins the immediate next cycle.

Note

The lockstep comparison is enabled by this write and cannot be disabled again without a reset.

4.3 LCM Redundant Module Configuration

In systems that do not require the redundant module output for comparison in functional safety requirements, the LCM redundant module can be used for functional output. To change the LCM comparators configuration upon device startup or after reset, the following steps must be taken at the beginning of the user application code:

1. Disable the redundant module using the following bit:
 - DEV_CFG_REGS[LSSEN.Enable = 0]
 - 24-cycle wait delay must be added after disabling lockstep, this is required for hardware to disable lockstep and then application can continue to execute in split core instances.

Note

The redundant lockstep module is supplied with a functional input and the comparison must also be disabled at this time. The configuration cannot be altered without a reset.

2. (Optional) Lock the LSEN configuration using the following bit:
 - DEV_CFG_REGS[DEVCFGLOCK2.LSEN = 1]

4.4 LCM Error Handling

Upon an error generated by the LCM module, an error event input is sent to the error signaling module (ESM). The ESM can be configured to take appropriate action that includes error status pin indication, generation of an interrupt or NMI to the CPU. The LCM error can be triggered by any of the following:

- Functional failure: LCM detecting an error (functional failure between the two modules).
- Self-test failure: LCM self-test failure detected (functional failure on one or both of the modules).
- Force Compare Error Request: Running LCM_CONTROL.CMPx_ERR_FORCE to force a compare error.
 - If the force compare error test passes, the error event is sent to the ESM and generates an NMI if configured in ESM. Inside the NMI routine, to differentiate between a functional failure of the device and a "force compare error test" induced failure, the LCM_STATUS.CMPx_ERR_FORCE_DONE flag can be read. This bit determines if the error-force test completed successfully (bit = 1, test complete) or never ran (bit = 0, test not completed). If the test never ran, then the NMI was triggered by an actual functional failure.

To determine the specific cause of the LCM error-induced NMI, the LCM_STATUS register bits can be read. Particularly:

- CMP_FAIL
- STPASS
- CMPx_ERR_FORCE_PASS
- CMPx_ERR_FORCE_DONE

For details on system-level NMIs vector locations and interrupt-handling, see [Chapter 5](#).

4.5 Register Parity Error Protection

The following critical LCM registers are protected by a parity scheme:

- LCM_CONTROL
- LCM_STATUS
- LCM_LOCK
- LCM_COMMIT

The parity scheme provides one parity bit per byte of data in the corresponding registers. Updates to any of the constantly-monitored registers causes an update to the parity bit. A single bit fault can therefore immediately flag an error. If the parity check determines a parity error has occurred, a dedicated error output line from the LCM module flags an error to the system.

All register parity errors (from the LCM) are sent as error inputs to the ESM module, refer to [Chapter 7](#) for more details.

Upon a parity error detection, SYSRSN must be asserted and the LCM_REGS[LCM_STATUS_CLEAR] register must then be cleared using the a write of 1 to all appropriate bits in the register.

Details on the self-test capability of the register parity error test are explained in [Section 4.6.3](#).

4.6 Functional Logic

This section describes the various logical blocks within the LCM that contribute to the goal of improved diagnostic coverage.

4.6.1 Comparator Logic

To implement lockstep scheme, a comparator block is needed. The comparator block compares the delayed version of relevant outputs of the primary module and the equivalent outputs of the secondary (redundant) module. This provides immunity towards the common cause failures like loss of power, clock failures, etc.

The LCM has two instantiations of the comparator block to provide redundancy of the comparator block. This enables availability of one comparator block during self-test of the other comparator block and also provides additional failure protection capability for the comparator logic.

Although the lockstep secondary (redundant) module is enabled upon startup, lockstep comparison must be enabled in software.

Once lockstep compare is enabled in software, the comparison is performed continuously every cycle, from the immediate next cycle. Any difference between the primary and secondary modules generates an error signal from the LCM to the SoC. The corresponding register bit is also set (LCM_STATUS.CMP_FAIL).

CPU reset (or any higher-level resets) disables the lockstep comparators, requiring re-enabling of the comparator in software.

4.6.2 Self-Test Logic

The self-test of the comparator has two different modes:

- Match Test
- Mismatch Test

These two tests are run together. Self-test is initiated by setting the appropriate register bit (LCM_CONTROL.STEN). When the self-test is initiated, the two different modes are executed on the two comparators one after the other. A self-test error also triggers error to ESM which can be configured to generate an NMI.

Redundant instantiation of the comparator block allows for one instantiation to be conducting a self-test while the other instantiation is active and performing the comparison check.

Self-test can also be performed before the comparator block is enabled in software.

Execution of the self-test is stopped immediately on failure. If either comparator fails the self-test, a status bit (LCM_STATUS.STPASS) is 0 instead of being set to 1.

During self-test, the LCM_STATUS.STACTIVE bit has a value of 1. Another self-test or compare error force must not be started until completion of the self-test, as indicated by LCM_STATUS.STDONE = 1.

The following subsections describe functionality of each of the individual test modes, Mismatch Test and Match Test.

4.6.2.1 Match Test Mode

The match test mode checks to make sure identical inputs on each comparator provide passing outputs. This makes sure that the comparator inputs and comparators themselves are working correctly and that a fault is successfully propagated to the module output.

This test is executed using two different patterns fed to the two inputs of each comparator (bit) in the comparator block: {0,0} and {1,1}. Both inputs can provide a passing output to the comparator since both patterns are providing identical inputs to both inputs of the comparator. This tests output-stuck-at-one, input-stuck-at-one, and input-stuck-at-zero issues. [Table 4-2](#) shows the test execution sequence for a single comparator in the comparator block.

Table 4-2. Match Test Simplified Example

Clock Cycle	A Input (Primary Module) of Comparator	B Input (Secondary Module) of Comparator	Output
0	0	0	0
1	1	1	0

4.6.2.2 Mismatch Test Mode

The mismatch test mode creates an error output of 1 on each individual comparator (bit) within the comparator block, one at a time. This makes sure that all comparators in the block are working correctly and that a fault is successfully propagated to the module output.

This test is executed using a walking 1s pattern to test for output-stuck-at-zero issues. The walking 1s pattern is where all comparators in the comparator block are zero except for one of the comparators.

For example, the primary module has a 1 at the spot that the secondary module has a 0. This can force an intentional error.

This is repeated for every comparator in the block, with the 1 being set on both modules. The passing scenario for this is that all comparators see a mismatch, flagging a mismatch each iteration. See [Figure 4-2](#) for a simplified illustration of how this is implemented for a comparator block with 8 comparators (not the number used in the actual design).

Cycle #	Secondary Module Signal								Primary Module Signal								Output
	7 (n)	6	5	4	3	2	1	0	7 (n)	6	5	4	3	2	1	0	
0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

15 (2n)	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Figure 4-2. Mismatch Test Simplified Example

4.6.3 Error Injection Tests

There are two error injection tests available for the LCM:

- Comparator Error Force Test
- Register Parity Error Injection Test

Each error injection test is run individually, as described in the following subsections.

4.6.3.1 Comparator Error Force Test

The LCM has the capability to force a fault to check the error signaling path between the LCM and ESM at the device level (for example, generate NMI, indicate error on ERRORSTS pin or trigger reset.) This test is executed separately from the self-test, and is executed on the primary and redundant comparators individually through separate calls.

Note

- The lockstep comparator must be enabled to execute this test.
 - Once this self-test is triggered, another self-test or compare error force request must not be triggered again until the current test is completed, as indicated by `LCM_STATUS.STDONE == 1`.
-

Execution of this self-test is started by setting the appropriate bit: `LCM_CONTROL.CMPx_ERR_FORCE`, where `x` is the number designator of the redundant comparator to be tested.

Upon execution of this one-cycle-long test, the LCM asserts a lockstep comparison error signal to the device. The normal functional compare fail flag (`LCM_STATUS.CMP_FAIL`) is not set by this test mode.

The following bits are set by the test:

- `LCM_STATUS` register:
 - `CMPx_ERR_FORCE_DONE` bit - 1 when the test is completed.
 - This bit must be cleared before running the test again for comparator "x".
 - `CMPx_ERR_FORCE_PASS` bit - 1 when the test passes.
 - This bit must be cleared before running the test again for comparator "x".

Because the test can trigger an NMI if configured in ESM on a test pass, the "DONE" flag allows the cause to be determined by either a functional fail or an error forcing test fail.

4.6.3.2 Register Parity Error Test

An error can be injected into the register parity error protection that exists for critical LCM registers, to test for latent faults. This error is inserted by forcing a particular byte to output a failing parity state to the system.

The test can be executed by running setting the `LCM_REGS[PARITY_TEST.TESTEN]` bits to the appropriate value.

Once the `TESTEN` register bits are set, the actual registers are no longer accessible in the memory map. Instead, the one bit parity error status values are accessible for every byte in the registers. Parity is computed for every byte, and the corresponding parity pass/fail value is available at the bit 0 location of every byte, in-place. A 0 in the bit 0 location corresponds to a pass; a 1 in the bit 0 location corresponds to a fail.

To actually inject an error, the value 1 can then be written to the bit 0 location of any byte. This inverts the stored parity value, and therefore inject an error into the parity test mechanism. Note that this propagates like an actual parity error in ESM and handled accordingly.

4.7 Software

4.7.1 LCM Registers to Driverlib Functions

Table 4-3. LCM Registers to Driverlib Functions

File	Driverlib Function

4.8 LCM Registers

This section describes the LCM Registers.

4.8.1 LCM Base Address Table

Table 4-4. LCM Base Address Table

Structure	DriverLib Name	Base Address	Frame Applicable	CPU1	CPU2	CPU3	RTDMA1	RTDMA2	HSM	Pipeline Protected
LCM_REGS ¹	LCM_CPU_BASE	0x3003_2000	-	YES	-	-	-	-	-	YES
LCM_REGS ¹	LCM_DMA_BASE	0x301F_4000	-	YES	YES	YES	-	-	YES	YES

- (1) Registers writeable by CPU1.LINK0, CPU1.LINK1, CPU1.LINK2 only. All CPUs can read all registers in all LINKs. Debug write access only allowed if Zone0 or Zone1 are enabled for full debug by all CPUs. Debug reads always allowed. Register Read/Write access by HSM.

4.8.2 LCM_REGS Registers

Table 4-5 lists the memory-mapped registers for the LCM_REGS registers. All register offset addresses not listed in Table 4-5 should be considered as reserved locations and the register contents should not be modified.

Table 4-5. LCM_REGS Registers

Offset	Acronym	Register Name	Protection
0h	REVISION	IP Revision tie-off value	
8h	LCM_CONTROL	LCM Control configuration	PARITY
20h	LCM_STATUS	LCM status register	PARITY
28h	LCM_STATUS_CLEAR	LCM Status clear register	
68h	PARITY_TEST	Enabling the parity test feature	
70h	LCM_LOCK	LCM lock configuration	PARITY
78h	LCM_COMMIT	LCM commit configuration	PARITY

Complex bit access types are encoded to fit into small table cells. Table 4-6 shows the codes that are used for access types in this section.

Table 4-6. LCM_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
WOnce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

4.8.2.1 REVISION Register (Offset = 0h) [Reset = 40000000h]

REVISION is shown in [Figure 4-3](#) and described in [Table 4-7](#).

Return to the [Summary Table](#).

Chapter 5

Peripheral Interrupt Priority and Expansion (PIPE) and C29 CPU Interrupts

This chapter describes the peripheral interrupt priority and expansion (PIPE) module and C29 CPU Interrupts. The PIPE module controls the peripheral interrupt handling on the device.

5.1 Introduction.....	808
5.2 Interrupts.....	808
5.3 Interrupt Controller Architecture.....	815
5.4 Interrupt Propagation.....	816
5.5 Configuring Interrupts.....	817
5.6 Safety and Security.....	832
5.7 Software.....	836
5.8 PIPE Registers.....	841

5.1 Introduction

Each PIPE module instance arbitrates peripheral interrupts for the respective CPU. All asserted interrupts are arbitrated each clock cycle, with the highest priority interrupt asserted to the corresponding CPU interrupt line (NMI, RTINT, or INT). The PIPE module is responsible for providing vector addresses to the CPU for NMI, RTINT, INT and RESET. The PIPE is capable of custom ordering of interrupts, prioritization, and nesting.

Note

Refer to the [C29x CPU Reference Guide](#) for information on the C29x CPU Interrupts Architecture including types of interrupts, interrupt functionality, and safety and security.

5.1.1 Features

The PIPE module has the following features:

- Hardware support for interrupt prioritization, arbitration, grouping, software hand-shake, and nesting.
- Dynamic arbitration of interrupts in hardware on every clock.
- Selectable priority level to choose interrupts as either RTINT and INT (including Supervisor INT).
- Interrupt grouping of adjacent-prioritized interrupts to block nesting within groups.
- Default index-based priority order for interrupts used in arbitration.
- Vector fetch support for RESET, NMI, RTINT, and INT.
- User access to the stack configured for INT.
- Contexts used by a software task manager system or operating system.
- Link-based protection verifies only legal code from the assigned interrupt owner services the interrupt.
- Device level protection validates only legal code source updates interrupt configuration and vector tables.
- Automatic context save and restore for RTINT and NMI.
- RTINT stack overflow protection always provides NMI a block of reserved stack space for execution.
- ECC protection for interrupt vector table.
- Parity protection for configuration registers.
- Optional locking capability of interrupt configurations.

5.1.2 PIPE Related Collateral

Foundational Materials

- [C29x Academy - Interrupts](#)

5.2 Interrupts

What are Interrupts?

Interrupts are hardware- or software-driven signals that cause the CPU to suspend current program sequence and execute a subroutine. Typically, interrupts are generated by peripherals or hardware devices that need to give data to or take data from the C29x CPU (for example ADC, DAC, EPWM, and other processors). Interrupts can also signal that a particular event has taken place (for example, a timer has finished counting).

C29x CPU Interrupts

On the C29x CPU, there are four types of interrupt lines in the system. These are listed here from highest priority to lowest priority:

- RESET
- NMI (non-maskable interrupts)
- RTINT (real-time interrupts, maskable)
- INT (low-priority interrupts, maskable, disableable)

These four interrupt lines handle all interrupts and exceptions on the device. All C29x devices come with a PIPE (Peripheral Interrupt Priority and Expansion) module that provides additional prioritization and arbitration of the

RTINT and INT lines. Details regarding the PIPE module are provided in the [F29H85x and F29P58x Real-Time Microcontrollers Technical Reference Manual](#).

5.2.1 CPU Interrupts Architecture Block Diagram

Figure 5-1 shows a block diagram of the C29x CPU interrupt architecture.

Figure 5-1. C29x CPU Interrupts Architecture Block Diagram

5.2.2 RESET, NMI, RTINT, and INT

This section explains the four interrupt lines available in the C29x CPU architecture.

5.2.2.1 RESET (CPU reset)

The CPU Reset is the highest-priority interrupt line, and occurs when the RESETn line receives an active-low signal. This causes the CPU to undergo a hardware reset internally. This cannot be aborted or nested-in.

All current and pending operations in the pipeline are aborted, and the pipeline is flushed during reset.

All CPU registers are reset to the reset value (all 0) as indicated in [Table 5-1](#).

Table 5-1. CPU Registers Reset Values

Registers	Reset Value
A0 through A15	0x0000 0000
D0 through D15	0x0000 0000
M0 through M31	0x0000 0000
DSTS	0x07F8 0000
ESTS	0x0000 0000
RPC	0x0000 0000
ISTS	0x0000 0000

5.2.2.1.1 Required Instructions (RESET)

NMI and RTINT interrupts can potentially have the respective interrupt service routines (ISRs) residing in a different LINK/STACK. Therefore, NMI and RTINT ISRs require that the first instruction packet of every vector address contain the (ISR1.PROT || ISR2.PROT) instructions. The CPU pipeline control hardware checks for these required instructions and generates a FAULT, if these instructions are not the first instruction packet of the ISR. These required instructions are inserted automatically by the compiler, but must be configured to do so for the appropriate vectors within a separate security settings file.

ISR1.PROT also initializes the stack pointer (A15) to the appropriate STACK by performing the following operation: A15 = SECSPn (where n is the current STACK indicated by ISTS.CURRSP).

5.2.2.2 NMI (Non-Maskable Interrupt)

The NMI (non-maskable interrupt) is the second highest-priority interrupt line, and receives system exception interrupts.

This NMI input line is used for any device-level critical condition and various faults either inside or outside the CPU that needs immediate attention.

5.2.2.2.1 Blocking and Masking (NMI)

NMIs cannot be masked or blocked in the CPU. There is no global enable/disable bit for the NMI line in the CPU. Because of this, any interrupts that are received on the NMI line are directly passed to the CPU for prioritization. Priority is then decided amongst the interrupt types (NMI, RTINT, and INT lines). NMI always has highest priority and asserts within any RTINT or INT currently executing. ATOMIC instructions in RTINT or INT ISRs cannot block or prevent NMI from asserting. ATOMIC instructions have no effect on NMI.

5.2.2.2.2 Signal Propagation (NMI)

The NMIn input to the CPU is typically generated from an Error Signaling Module (ESM) unit located outside the CPU. Such a unit allows for aggregation and prioritization of system faults. Even fault conditions that occur internal to the CPU propagates the fault information to a common device level aggregator unit, which then generates an NMI back to the CPU.

The NMIn input latches inside the CPU, and is handled with higher priority than all other interrupt types (except Reset events).

5.2.2.2.3 Stack (NMI)

This interrupt line uses the protected Real Time Interrupt Stack for context save and restore. This protected stack has features to prevent stack overflow during nesting, when nesting is requested by the PIPE module. The WARNRTISP and MAXRTISP CPU registers serve this purpose in the C29x CPU system.

This protection limits nesting of RTINT up to the number of levels supported by the RTINT Stack minus one level (which is always reserved for NMI interrupt).

For security, the device-level protections of the RTINT Stack are designed so that the contents of the stack are not visible. Registers are also zeroed to prevent visibility into what was happening before the interrupt was serviced.

See for details on stack overflow protection using the WARNRTISP and MAXRTISP registers.

5.2.2.2.4 Required Instructions (NMI)

NMI and RTINT interrupts can potentially have the respective interrupt service routines (ISRs) residing in a different LINK/STACK. Therefore, NMI and RTINT ISRs require that the first instruction packet of every vector address contain the (ISR1.PROT || ISR2.PROT) instructions. The CPU pipeline control hardware checks for these required instructions and generates a FAULT, if these instructions are not the first instruction packet of the ISR. These required instructions are inserted automatically by the compiler, but must be configured to do so for the appropriate vectors within a separate security settings file.

ISR1.PROT also initializes the stack pointer (A15) to the appropriate STACK by performing the following operation: A15 = SECSPn (where n is the current STACK indicated by ISTS.CURRSP).

5.2.2.3 RTINT (Real-Time Interrupt)

The RTINT (real-time interrupt) is the third highest-priority interrupt line, and receives signals driven by an interrupt expansion and aggregation unit (the PIPE module for most C29x CPU systems).

5.2.2.3.1 Blocking and Masking (RTINT)

RTINT sources are able to be masked, but the actual RTINT line connected to the CPU can never be blocked/disabled by user code. There is no global enable/disable bit for the RTINT line in the CPU. Because of this, any interrupts that are received on the RTINT line are directly passed to the CPU for prioritization. Priority is then decided among any interrupts on the NMI or INT lines. The RTINT signal line can only be stopped from nesting within INTs by using the ATOMIC instruction within the INT ISR, and only for a finite number of instruction packets. However, interrupts ISRs can be prioritized/blocked before the interrupts reach the RTINT line using the external PIPE module.

5.2.2.3.2 Signal Propagation (RTINT)

The PIPE module provides external interrupt aggregation and arbitration for the RTINT and INT lines. This allows for many signals to be categorized as real-time interrupts (RTINT) or low-priority interrupts (INT), and then prioritized before passing to the CPUs RTINT or INT interrupt line.

The PIPE effectively multiplexes the single RTINT CPU interrupt line to be able to receive from multiple incoming RTINT interrupts in the appropriate order.

The module allows for enabling and disabling of RTINT signals before the signals reach the RTINT line of the CPU. The module also allows nesting capability amongst other interrupts categorized as RTINT. See the device-specific Technical Reference Manual for details on the PIPE module features.

5.2.2.3.3 Stack (RTINT)

This interrupt line uses the protected Real Time Interrupt Stack for context save and restore. This protected stack has features to prevent stack overflow during nesting, when nesting is requested by the PIPE module. The WARNRTISP and MAXRTISP CPU registers serve this purpose in the C29x CPU system.

This protection limits nesting of RTINT up to the number of levels supported by the RTINT Stack minus one level (which is always reserved for NMI interrupt).

For security, the device-level protections of the RTINT stack is designed so that the contents of the stack are not visible. Registers are also zeroed to prevent visibility into what was happening before the interrupt was serviced.

See for details on stack overflow protection using the WARNRTISP and MAXRTISP registers.

5.2.2.3.4 Required Instructions (RTINT)

NMI and RTINT interrupts can potentially have the respective interrupt service routines (ISRs) residing in a different LINK/STACK. Therefore, NMI and RTINT ISRs require that the first instruction packet of every vector address contain the (ISR1.PROT || ISR2.PROT) instructions. The CPU pipeline control hardware checks for these required instructions and generates a FAULT, if these instructions are not the first instruction packet of the ISR. These required instructions are inserted automatically by the compiler, but must be configured to do so for the appropriate vectors within a separate security settings file.

ISR1.PROT also initializes the stack pointer (A15) to the appropriate STACK by performing the following operation: A15 = SECSnP (where n is the current STACK indicated by ISTS.CURRSP).

5.2.2.4 INT (Low-Priority Interrupt)

The INT (low-priority interrupt) is the lowest-priority interrupt line, and receives signals driven by an interrupt expansion and aggregation unit (the PIPE module for most C29x CPU systems). This interrupt line is typically used for lower priority operations and task schedulers.

5.2.2.4.1 Blocking and Masking (INT)

INT sources are able to be masked, and the INT line can also be blocked/disabled by user code using the DSTS.INTE enable bit. If DSTS.INTE is enabled, then any interrupts received on the INT line are directly passed to the CPU for prioritization. Priority is then decided among the interrupts on the NMI or RTINT lines. To prevent an RTINT interrupt from nesting within a INT interrupt, the ATOMIC instruction can be used for a finite number of instruction packets.

On entering a INT ISR, further INTs are automatically disabled using the DSTS.INTE bit. To allow nesting, enable interrupts using the ENINT instruction. There also exists a DISINT instruction for disabling the INT line again.

Note

The C29x CPU also provides a special INT referred to as a Supervisor Interrupt which bypasses the DSTS.INTE setting. For example, a Supervisor Interrupt can be used for a certain task monitor event which requires the interrupt to not get blocked by erroneous setting of the DSTS.INTE. Task manager events are often precisely timed events needing priority over regular interrupts. However, new INT interrupts are normally blocked during ISR execution, causing timing variance for task manager events.

Within the PIPE module, if the INT_CONFIGx.PRI_LEVEL == INT_RTINT_THRESHOLD and TASK_CTRL.SUP_IGN_INTE_EN is enabled, the incoming interrupt is a Supervisor INT. With these settings, the CPU acknowledges the INT regardless of INTE status and does not accept any new INT till its re-enabled. The ongoing INT execution is nested in by the Supervisor Interrupt.

5.2.2.4.2 Signal Propagation (INT)

The PIPE module provides external interrupt aggregation and arbitration for the RTINT and INT lines. This allows for many signals to be categorized as real-time interrupts (RTINT) or low-priority interrupts (INT), and then prioritized before passing to the CPU's RTINT or INT interrupt line.

The PIPE effectively multiplexes the single INT CPU interrupt line to be able to receive from multiple incoming INT interrupts in the appropriate order.

The module allows for enabling and disabling of INT signals before the signals reach the INT line of the CPU. The module also allows nesting capability amongst other interrupts categorized as INT or RTINT. See the device-specific Technical Reference Manual for details on the PIPE module features.

5.2.2.4.3 Stack (INT)

Unlike the NMI or RTINT interrupt lines, the INT line uses the standard software stack for context save and restore. Only one of the multiple available CPU stacks can be used for INT. This is configured by the INTSP register in the external PIPE module. If an INT vector points to the wrong LINK which is associated with a different STACK (security-assigned stack), then an NMI fault is generated.

If the current stack pointer is not pointing to the INTSP, then any pending INT remains pending until the stack pointer points to the selected INTSP stack.

5.2.3 Conditions Blocking Interrupts

There are certain CPU pipeline conditions that cause an uninteruptible boundary for the CPU. These conditions prevent entry of interrupts until the conditions are over, effectively blocking interrupts during the hold time. [Table 5-2](#) explains these situations:

Table 5-2. Conditions That Block Interrupts

Condition Description	INT Blocked	RTINT Blocked	NMI Blocked
Conditional instructions in packet not all completed	Yes		
Discontinuity instruction delay slot not completed			
Multicycle instructions like branch, call, return not completed			
For CALL.PROT instruction: first instruction at the call destination not executed			
For RET.PROT instruction: first instruction of the return address not executed			
The first instruction of the previous asserted interrupt has entered the D2 stage			
CPU "pipeline ready" not asserted			
CPU pipeline stalled due to memory RD/WR access			
CPU pipeline stalled due to no instruction in the instruction buffer			
Instruction packet stalled in D2 phase of pipeline due to pipeline hazard, but the packet is not ready to move to R1 phase of pipeline.			
LP Interrupt is disabled in DSTS.INTE	Yes	NO	
ATOMIC instruction counter not completed	Yes		NO

5.2.3.1 ATOMIC Counter

The C29x CPU supports an instruction “**ATOMIC.REG #u8**” that loads an internal counter (ISTS.ATOMIC COUNTER) with an 8-bit value. This counter decrements once for each instruction packet executed. As long as this atomic counter is not zero, an interrupt (RTINT or INT) cannot enter the CPU pipeline. Hence, this instruction allows the user code to block interrupts for up to 256 instruction packets.

Restrictions on the use of ATOMIC instruction:

- The ATOMIC instruction cannot be in the delay slot of any discontinuity instruction or executed in parallel to a branch instruction.
- The ATOMIC instruction cannot be in parallel to any discontinuity instruction.
- Executing ATOMIC instructions back to back cannot be used to block interrupts beyond the maximum count.
- Executing an ATOMIC instruction when the ATOMIC count is not zero resets the ATOMIC counter.
- Protected calls and returns reset the ATOMIC counter.
- The ATOMIC instruction or counter CANNOT block NMI. Anytime the ISTS.NMIF flag is set (indicating that a NMI event has been registered), the NMI is taken and the ATOMIC counter is reset.

5.3 Interrupt Controller Architecture

The PIPE module has three primary functional blocks:

1. Dynamic Priority Arbitration Circuit
2. Post Processing Block
3. Memory-Mapped Registers (includes vector table and bus interface)

These three blocks are explained in detail in the following subsections.

Figure 5-2. PIPE Architecture

5.3.1 Dynamic Priority Arbitration Block

The dynamic priority arbitration block provides the CPU with the highest priority interrupt vector that is available every clock cycle. The CPU processes the highest priority interrupt at the provided vector address.

5.3.2 Post Processing Block

The post processing block takes the highest priority interrupt that won the arbitration process and selects which interrupt line (INT or RTINT) to forward the interrupt to. The post processing block also automatically checks which link is accessing an interrupt line and whether a secure link is accessing protected registers.

Note

The NMI line provided to the CPU is an independent line that overrides any other interrupt (INT or RTINT) ready for assertion.

5.3.3 Memory-Mapped Registers

The memory-mapped registers (MMR) contain the interrupt configuration registers. Below are the type of registers available in the memory-mapped registers:

- Link associated with each interrupt.
- Priority configured for each interrupt.
- Interrupt configurations.
- Interrupt status.
- Vector table.

Accesses are controlled by the same security rules that apply to all registers.

5.4 Interrupt Propagation

Interrupts propagate to the CPU through several steps. Peripheral interrupts set the corresponding FLAG bit in the INT_CTL_REG_L_y register of a given interrupt. If the EN bit of the interrupt's INT_CTL_REG_L_y register is set, the interrupt propagates to the dynamic priority arbitration circuit. Next, the dynamic priority arbitration block and post processing block arbitrate the highest-priority interrupt and assert this to the CPU on one of the two interrupt lines (RTINT or INT). Finally, the CPU chooses the highest-priority interrupt line that is asserted (amongst NMI, RTINT, and INT) and begins execution of that interrupt.

Note

The CPU_INT_STS reflects whether an INT or RTINT interrupt was acknowledged most recently as well as the interrupt priority level, providing further insight into interrupt timing sequences.

Figure 5-3. Interrupt Propagation

Note

NMI is an independent line that overrides any other interrupts ready for assertion. An NMI event asserted to PIPE is forwarded to the CPU, including NMI in service. CPU can select a new NMI at any time, but the PIPE module does not forward the new NMI until the in-service NMI interrupt service routine is complete.

The same rule is applicable to RESET. Once the CPU receives the RESET, there are no conditions to meet before reset assertion to CPU.

Refer to the [C29x CPU Reference Guide](#) for how the NMI, RTINT, and INT (including Supervisor INT) types of interrupts propagate once within the C29x CPU.

5.5 Configuring Interrupts

At power-up, all interrupts return to the default reset conditions:

- All interrupts are disabled.
- All interrupts are set to the default priority (INT_CONFIG.PRI_LEVEL).
- All interrupts are set to the default context (INT_CONFIG.CONTEXT_ID).
- All interrupts are assigned as INT by default (RTINT_THRESHOLD.INT_RTINT_THRESHOLD).
- All interrupt vectors point to the default NMI vector (INT_VECT_ADDR.*).
- Stack pointer warning levels are reset to default values (RTINT_SP_H.*).
- All interrupt owner and API links are set to a default link (INT_LINK_OWNER.*). The user must update the link configurations to SROOT_LINK (LINK2) to be able to configure the PIPE irrespective of SSU mode of operation.

Interrupts are configured as follows:

1. **Initialization:** Initialize PIPE MMR and memory. Set interrupts to LINK2 and INTSP to STACK2. Initialize the PIPE vector table for CPU1.
2. **Disable INT and RTINT:** Disable INT and RTINT using the GLOBAL_EN.ENABLE/KEY fields.
3. **Threshold:** Set the RTINT Threshold and Interrupt Priority Threshold.
4. **Nesting:** Set the group mask, as required.
5. **Stack protection:** Set stack pointer warning levels (RTINT_SP_H.*), as required.
6. **Interrupt Vector:** Specify the handler function to be called per interrupt source.
7. **Enabling Interrupts:** Enable required interrupts using INT_CTL_L_y.EN bit for each interrupt.
8. **Prioritization:** Set the interrupt priority, as required.
9. **Context:** Set the context ID, as required.
10. **Enabling INT and RTINT:** Enable INT and RTINT using the (1) CPU INT ENABLE and (2) PIPE GLOBAL_EN.ENABLE/KEY bits.

Note

The following actions must be done within an ATOMIC block for predictable CPU behavior:

- Enabling Interrupts.
- Disabling Interrupts.

Interrupts can be re-configured while GLOBAL_EN is enabled. However, interrupts that have already been forwarded from the PIPE to the CPU and have reached the CPU, being serviced, or are nested-in are not affected by any re-configuration changes. These settings do not apply until the next interrupt is forwarded from the PIPE to the CPU.

Note

As explained in the [C29x CPU Reference Guide](#), the CPU is in an uninterruptible boundary while servicing an interrupt. For that reason, it is essential to perform a SYSRsn before performing other actions such as loading code. Otherwise, further interrupts from the PIPE will not propagate to the CPU.

5.5.1 Enabling and Disabling Interrupts

Individual interrupts can be enabled first, using the INT_CTL_L_y.EN register bit. Once the desired interrupts are enabled at the peripheral level coming into PIPE, the user can then enable the PIPE module to begin forwarding interrupts to the CPU.

To enable the PIPE to forward INT and RTINT interrupts to the CPU, GLOBAL_EN.ENABLE/KEY bits must be set properly. See the register description for GLOBAL_EN register for values required for enabling the PIPE forwarding.

When disabling interrupts, caution must be taken to avoid unexpected interrupts from occurring. The following steps must be taken when disabling one or more interrupts:

1. Global disable PIPE interrupts (GLOBAL_EN.ENABLE).
2. Disable the individual interrupts desired (INT_CTL_L.EN).
3. Wait 6 cycles for any ongoing arbitration to complete.
4. Global enable PIPE interrupts (GLOBAL_EN disable).

Note

In this chapter, references to the global enable are referring to the GLOBAL_EN within the PIPE module that is different than the DSTS.INTE within the CPU that is needed to propagate INTs to the CPU.

5.5.2 Prioritization

The PIPE arbitrates incoming interrupts based on interrupt priority, with the lowest value being the highest priority. Priority is determined for each interrupt using two different values:

1. User-configured interrupt priority.
2. Index-based fixed interrupt priority.

5.5.2.1 User-Configured Interrupt Priority

User-configured interrupt priority is configured in software through the INT_CONFIG.PRI_LEVEL field that exists for every interrupt. The lower the PRI_LEVEL, the higher the priority of the interrupt. For example, an interrupt with PRI_LEVEL = 0 is serviced before an interrupt with PRI_LEVEL = 1 if both arrive at the same time.

When multiple interrupts are configured to the same PRI_LEVEL, the interrupts with the same PRI_LEVEL use the index-based fixed interrupt priority to determine the highest priority interrupt.

Note

By default every interrupt is configured to the highest PRI_LEVEL value (lowest priority). Therefore, all interrupts use index-based fixed interrupt priority by default.

5.5.2.2 Index-Based Fixed Interrupt Priority

The input number at which a particular interrupt is connected to the PIPE is called the "interrupt index". This is the index-based fixed interrupt priority that is fixed per device. This is also the indexing used to configure the interrupts in the PIPE.

For example, the INT_CONFIG register is repeated for every interrupt, and is indexed as INT_CONFIG_y (where y is the index of each interrupt).

Table 5-3 shows the "interrupt index" for all peripheral interrupt channels on this device.

Note

Refer to the peripheral-specific chapters for interrupt source details and usage instructions.

Note

All PIPE interrupts are pulse interrupts, except CPUTimer, SPI, and Crypto Peripheral interrupts (TRNG, PKA, SHA, SM) which are level triggers. This recommended interrupt handling process can be followed for level interrupts to avoid unnecessary interrupts getting triggered:

1. Enter ISR.
2. Perform ISR functions.
3. Clear interrupt status within peripheral.
4. Poll for interrupt flag status to be cleared or wait for peripheral interrupt status to be cleared using NOPs.
5. Write to INT_{#}_CTL_REG_H.FLAG_CLR to clear the INT_{#}_CTL_REG_L.FLAG in software.
6. Wait for the PIPE flag to get cleared by writing 7 NOPs.
7. Exit ISR.

In addition, for level-triggered PIPE interrupts, using the OVERFLOW_FLAG is not the recommended method to determine if a second interrupt occurred before the first interrupt is serviced due to the nature of level interrupts. Instead, users can use peripheral-specific interrupt flags, when possible.

5.5.3 Interrupt Nesting

Nesting is supported at the hardware level in the C29x CPU. At the CPU interrupt level, nesting is possible amongst the three non-reset interrupt lines (NMI_n, RTINT_n, INT_n). Interrupt lines can nest inside the ISR of lower priority interrupt lines. So an NMI can nest within RTINT or INT. RTINT can nest within INT. INT cannot nest in other interrupt lines. However, additional nesting within interrupt types RTINT and INT is possible using the PIPE module.

A detailed look at the nesting available on the C29x CPU is explained below (along with the expanded abilities afforded by the PIPE module).

NMI: No interrupt (including other NMIs) can nest within an NMI that is currently running. Anytime the ISTS.NMIF flag is set (indicating that a NMI event has been registered), the NMI is taken and the ATOMIC counter is reset.

RTINT: NMIs always nest within RTINT. This nesting cannot be stopped with the ATOMIC instruction. Using the PIPE module, higher priority RTINTs can nest within lower priority RTINTs. The ATOMIC instruction can delay entry of a nested RTINT until the ATOMIC counter expires.

INT: NMIs always nest within INT. This nesting cannot be stopped with the ATOMIC instruction. RTINTs always nest within INT, but the ATOMIC instruction can delay entry of a nested RTINT until the ATOMIC counter expires. Using the PIPE module, higher priority INTs can nest within lower priority INTs. The ATOMIC instruction can delay entry of a nested INT (or RTINT) until the ATOMIC counter expires.

5.5.3.1 Interrupt Nesting Example Diagram

Figure 5-4. Interrupt Nesting Example Diagram

5.5.3.2 Nesting and Priority Grouping

Grouping Interrupts Based on Priority Levels

The PIPE also allows for interrupts to prevent nesting within other interrupts using "groups". Interrupts in a given group do not preempt or nest within other interrupts in the group.

To form a group, the least significant bits of the priority (INT_CONFIG.PRI_LEVEL) are used to choose which interrupts are in the same group. The number of least significant bits of the INT_CONFIG.PRI_LEVEL that is used for grouping interrupts is also configurable (masked using the INT_GRP_MASK register) in binary multiples (ex: 2, 4, 8, 16). Groups are made up of interrupts that are near one another in configured priority levels.

Note

The RTINT_THRESHOLD needs to be aligned with the configured group mask to maintain proper RTINT behavior. The PIPE module first groups the interrupts and then processes them to be RTINT or INT. In other words, grouping takes priority over RTINT resolution based on the threshold value.

For example when this above note is not followed, some group includes both priority levels INT_7 and INT_29 and the RTINT_THRESHOLD is set to 10. If the CPU was servicing INT_29 (INT) and INT_7 comes (RTINT), irrespective of the RTINT threshold, INT_7 is not forwarded on RTINT/INT lines.

The group mask combinations possible are outlined in [Table 5-4](#). Any other group mask chosen for INT_GRP_MASK that is not listed in [Table 5-4](#) results in using the default group mask of 0xFF where all interrupts can nest.

Table 5-4. Group Mask Combinations

Group Mask	Group Size	Number of Groups	Priority Assignment Distance	Comment
0xFF/Other	1	256	1	0xFF: All interrupts can nest in one another. All interrupt levels are in individual groups, so 256 configurable priorities are available with 1 interrupt level in each. All other values: If any other value is used, the mask value defaults to 0xFF that correlates to no group mask.
0xFE	2	128	2	128 priority groups with 2 interrupt levels in each; hence, the number of priorities reduce to 128 for preemption.
0xFC	4	64	4	64 priority groups with 4 interrupt levels in each; hence, the number of priorities reduce to 64 for preemption.
0xF8	8	32	8	32 priority groups with 8 interrupt levels in each; hence, the number of priorities reduce to 32 for preemption.
0xF0	16	16	16	16 priority groups with 16 interrupt levels in each; hence, the number of priorities reduce to 16 for preemption.
0xE0	32	8	32	8 priority groups with 32 interrupt levels in each; hence, the number of priorities reduce to 8 for preemption.
0xC0	64	4	64	4 priority groups with 64 interrupt levels in each; hence, the number of priorities reduce to 4 for preemption.
0x80	128	2	128	2 priority groups with 128 interrupt levels in each; hence, the number of priorities reduce to 2 for preemption.
0x00	256	1	256	No interrupts can nest in one another. All interrupts are in one group, so configurable priorities are used for the highest priority interrupt. There is no nesting of interrupt priority levels regardless of INT or RTINT status.

For example, in the case of an interrupt with priority level 13, this interrupt can belong to different groups depending on the group mask: 0xFF: Group 14, 0xFC: Group 11, 0xF8: Group 4, and so on.

Figure 5-5 illustrates one example of how grouping allows interrupts to nest, and is shown with PRI_LEVEL 0 to 7 set and group sizes selected as shown. In this example, no two interrupts have the same interrupt priority level configurations.

Figure 5-5. Interrupt Grouping

5.5.4 Stack Protection

INT uses the software stack that is configured in the INTSP register. The INT stack has no hardware stack overflow protection. Software can be used to implement a software stack overflow protection scheme for the INT stack as required.

RTINT and NMI use the RTINT stack which is a dedicated hardware stack used for RTINT and NMI context save and restore.

Context save for RTINT and NMI executes the following in hardware automatically upon ISR entry:

- Increment RTISP (interrupt stack pointer for RTINT stack).
- Transfer all CPU registers to RTINT stack.
- Clear CPU registers before ISR start.

Context restore for RTINT and NMI executes the following in hardware automatically upon ISR exit:

- Copy all CPU registers back from RTINT stack.
- Decrement RTISP.

To avoid excessive nesting of the RTINT stack leading to stack overflow, the CPU tracks the level of nesting on RTINT and outputs this information to the PIPE.

RTINT WARNRTISP

The first line of defense against stack overflow is the user-configurable RTINT_SP_H.WARNRTISP register field. The number of stack blocks used by the RTINT stack (counted by RTISP) is compared to the level configured in RTINT_SP_H.WARNRTISP. If RTISP is greater than or equal to RTINT_SP_H.WARNRTISP, the PIPE changes which interrupts are allowed to be asserted: only interrupts with a priority level higher than the user-configured RTINT_SP_H.WARNRTISP_PPIO_LEVEL are allowed. This can be summarized using the pseudo-code:

```
if(RTISP >= RTINT_SP_H.WARNRTISP){
    Only allow RTINT with INT_CONFIG.PRI_LEVEL < RTINT_SP_H.WARNRTISP_PPIO_LEVEL
}
else{
    Allow all RTINT.
}
```

The status of whether or not RTISP level has reached the user-configured WARNRTISP level is located in the RTISP_STS.WARNRTISP_STS field.

Note

WARNRTISP must not be configured as 0 to avoid immediately firing an error on a register write.

WARNRTISP must not be configured as 1 to avoid firing an error to the ESM on the first RTINT occurrence. However, there is no impact if the user is not utilizing and/or expecting any RTINT.

RTINT MAXRTISP

When RTINT_SP_L.RTISP = RTINT_SP_L.MAXRTISP, all RTINT stack space **except one stack slot** has been exhausted which is used by a NMI to alert the CPU of the overflow. When this condition is true, the PIPE does the following:

- Stops asserting any and all new RTINTs to the CPU.
- Raises a fault to the Error Signaling Module (ESM).
- Sets this max breach status in RTISP_STS.MAXRTISP_STS.

The MAXRTISP puts the CPU in a fault state, and the ESM responds to the PIPE fault assertion by raising an NMI back to the PIPE. However, PIPE does not allow for nesting of NMIs. PIPE only allows further RTINTs to execute once the second-to-last stack slot is available again in the RTINT stack. A system reset is required to recover the device from fault.

Note

The NMI MAXRTISP error occurs when there are **no available slots** in the RTINT stack space. The hardware response is similar to that of RTINT MAXRTISP. This condition should not occur as PIPE does not allow nesting of NMI. It is an additional safety check within the CPU to avoid RTINT stack overflow.

5.5.5 Context

PIPE allows arbitrated interrupts to be grouped into smaller sets to effectively create multiple execution contexts. This feature can be used when executing interrupts across multiple stacks and interrupts on different stacks are operating at different time slots (that is, interrupts in one context at a time). For example, these contexts can be used by a software task manager system or operating system. The Interrupt Controller is configured to only arbitrate interrupts whose context matches the "active context." Two related but distinct fields control this:

Field	Scope	Definition
TASK_CTRL.ACTIVE_CONTEXT_ID	Global	Which context the controller is <i>currently arbitrating for</i> .
INT_CONFIG.CONTEXT_ID	Individual interrupt	Which context a <i>given interrupt</i> belongs to.

Only interrupt lines whose CONTEXT_ID matches the current ACTIVE_CONTEXT_ID participate in arbitration and execute their corresponding ISRs. The stacks, links, and so on, associated with each interrupt need to be configured accordingly depending on the application.

Table 5-5. Context-ID Mapping

ACTIVE_CONTEXT_ID	Context Type
0x00	Context-0 - Default context.
0x01	Context-1
0x10	Context-2
0x11	Interrupts which are context-agnostic and/or participate in arbitration regardless of ACTIVE_CONTEXT_ID.

Example: An OS runs Context-0 tasks on the main stack and Context-1 tasks on a secondary stack, switching ACTIVE_CONTEXT_ID between the two as it schedules work. A timer ISR configured with CONTEXT_ID = 0b11 continues to fire and arbitrate normally no matter which task context is currently active.

Any updates to ACTIVE_CONTEXT_ID and CONTEXT_ID take place on the next arbitration cycle. Changing the active context or context ID does not stop accumulation of interrupt events that are out of context. This only disables interrupt participation in arbitration. Any interrupts that are already in service or nested have no effect on this setting.

Note

GLOBAL_EN.ENABLE must be disabled before changing ACTIVE_CONTEXT_ID. This is done to avoid disrupting the priority arbitration as interrupts can become disabled and out of arbitration and/or enabled and join arbitration.

After ACTIVE_CONTEXT_ID is modified, software must wait at least 6 system clock cycles for arbitration to be completed before re-enabling GLOBAL_EN.ENABLE.

5.5.6 Live Firmware Update (LFU) Vector Mapping

There are two sets of memory mapped vector tables supported by PIPE:

- Default vector table - Used for standard operation in application code.
- LFU PIPE vector table - Used for LFU operation.

When performing an LFU, users can update the interrupt vectors with minimal impact on timing by populating the inactive vector table and then swapping to it by modifying the LFU_INT_VECT_MAPPING field in the INT_VECT_MAPPING register. Unlike with A/B flash bank swap, these vector tables reside at two different memory addresses.

For more information on LFU, refer to the Safety and Security and Flash Module chapters.

5.6 Safety and Security

The PIPE has protection mechanisms to provide safety and security for the interrupt architecture.

5.6.1 Access Control

The C29 pipeline enforces access privileges for vector table and registers as explained in [Table 5-6](#). Link-based protection verifies that only legal code from the assigned interrupt owner can service the interrupt. Device-level protection validates that only legal code sources can update interrupt configuration and vector tables.

Table 5-6. Access Privileges

Access Privilege	Accessing Link	Reason	C29 and PIPE Access Conditions
OWNER_LINK	Configured owner link of interrupt line	Only the OWNER_LINK of the particular interrupt line is allowed to update or read the operational registers such as flag RD/SET/CLR, status RD, etc.	CURRLINK=OWNER_LINK
API_LINK	Configured API link of interrupt line	Common-code link access is permitted when the API_LINK is set because ISR code that updates the PIPE is often shared across different interrupts across different links. Access is permitted only when called by the interrupt's OWNER_LINK.	CURRLINK=API_LINK && API_LINK_EN='1' && CLINK=OWNER_LINK
SROOT_LINK	Secure Root Link (LINK2)	SROOT_LINK is the most trusted, secure link with access to all the PIPE registers to configure interrupts and handle exceptions beyond the regular ISR.	CURRLINK=SROOT_LINK
BOOT_LINK	Boot link (LINK1)	BOOT_LINK configuration is required to configure PIPE and handle peripheral interrupts during the boot process. For a short period, before application code begins, access is granted as long as the BOOT_LINK_LOCK is not set. Once the boot process completes, either the BOOT_LINK or SROOT_LINK shall update the BOOT_LINK_LOCK, disabling access.	CURRLINK=BOOT_LINK && BOOT_LINK_LOCK = '0'

Note

Refer to the *C29x CPU Reference Guide* for more information on how the C29x CPU determines the necessary conditions for proper interrupt execution. In addition to the link-based protections mentioned above, there are checks related to stack association and CPU pipeline conditions to keep in mind.

5.6.2 PIPE Errors

The PIPE module is directly connected to the Error Aggregator that aggregates errors occurred during interrupt related errors such as interrupt service routines (ISRs). PIPE outputs the error, error type, and error address to the Error Aggregator. The errors from the CPUx and associated PIPE instance are combined as CPUx INT.

The errors are propagated to the ESM, PIPE, and CPU to take the appropriate action, typically a NMI. [Table 5-7](#) summarizes the various types of errors that can occur with INT, RTINT, NMI, RESET, and overall PIPE module.

Note

The MAIN state describes when CPU is in a RESET or not in any task, interrupt, or exception.

Table 5-7. CPUx INT Error Aggregator Errors

CPUx INT Interface Errors	Priority	Description
MAIN/INT/RTINT/NMI ISR ENTRY ERROR	HIGH	Error in entering an interrupt service routine for a specific interrupt type. RESET / NMI / RTINT ISRs require that the first instruction packet of every vector address contains the (ISR1.PROT ISR2.PROT) instructions.
MAIN/INT/RTINT/NMI CORRECTABLE VECTOR ERROR	LOW	Reading interrupt vector and/or link register related to a specific interrupt type that results in a single-bit ECC error.
MAIN/INT/RTINT/NMI UNCORRECTABLE VECTOR ERROR	HIGH	Reading interrupt vector address related to a specific interrupt type that results in a double-bit ECC error.
MAIN/INT/RTINT/NMI INTERRUPT RETURN ERROR	HIGH	Error in exiting an interrupt service routine for a specific interrupt type. NMI / RTINT ISRs require that the last instruction packet of every vector address contains the (RET1.RTINT) instruction. INT ISRs require that the last instruction packet of every vector address contains the (RET1.INT) instruction.
RTINT/NMI CONTEXT RESTORE CORRECTABLE ERROR	LOW	CPU data fetched from the RTINT hardware stack results in a single-bit ECC error.
RTINT/NMI CONTEXT RESTORE UNCORRECTABLE ERROR	HIGH	CPU data fetched from the RTINT hardware stack results in a double-bit ECC error.
NMI MAXRTISP ERROR	HIGH	CPU current interrupt stack pointer has reached the RTINT stack limit, including the reserved slot for NMI. When CPU returns from NMI ISR, the CPU can hang as the NMI execution and context save/restore is occurring on the same stack.
PIPE VECTOR INIT CORRECTABLE ERROR	LOW	PIPE reads interrupt vector address that results in a single-bit ECC error.
PIPE VECTOR INIT UNCORRECTABLE ERROR	HIGH	PIPE reads interrupt vector that results in a double-bit ECC error.
PIPE WARNRTISP	LOW	CPU current interrupt stack reaches or exceeds the value of the WARNRTISP Threshold. NOTE: This error is only automatically cleared when the interrupt stack pointer value falls below this threshold.
PIPE RTINT MAXRTISP	HIGH	CPU interrupt stack pointer has reached the RTINT stack limit (NMI reserved slot excluded). Refer to the registers for the device-specific hardcoded value.
PIPE SECURITY VIOLATION	HIGH	Unsecure access is made by illegitimate code during a PIPE register read and/or write.
PIPE REG PARITY ERROR	HIGH	Parity mismatch in a PIPE register and the respective stored parity value.
PIPE REGISTER PARITY DIAG ERROR	LOW	To determine if the parity checkers in the diagnostics registers are working correctly, user injects an error intentionally into this parity checker to see if an error is being generated as expected.
PIPE LOCK KEY ERROR	LOW	Locked register is written to or a wrong key is used for a keyed register.

Note

Refer to the chapters of the error handling modules for the complete list of error sources and guidelines on how to further debug error conditions.

5.6.3 Register Data Integrity and Safety

The PIPE vector table and critical configuration registers have ECC protection. All other PIPE configuration registers have parity protection. The registers with parity-protection are mentioned in the registers section of this chapter.

5.6.4 Self-Test and Diagnostics

For diagnostics of safety mechanisms, ECC logic needs to be checked periodically. However, running test-of-diagnostics in software to check ECC logic is time consuming as many patterns have to be run to get to the required coverage. To enable seamless diagnostics, self-test logic is added.

The self-test controller generates test sequences to detect faults in ECC logic. Any errors found as part of the test sequences is logged into self-test configuration registers that are part of the PIPE module. Different data patterns can be required to get additional coverage. The input data and ECC values to the ECC logic is programmable through self-test registers.

If at any point the software reads the INT_VECT_ADDR registers to perform ECC checks on the read vector address value, any enabled self-test sequences are paused. Software is required to continually poll for the completion status of the self-test sequences to account for such pauses.

The self-test controller can run the following test sequences, see [Figure 5-6](#), to detect an error in ECC logic:

1. Positive check: Input pattern (Data, Address, ECC bits) that is written does not result in ECC errors. No errors are generated by the ECC logic when none are expected.
2. 1-bit error check: Single bit errors are induced sequentially and then checked for the expected correctable error.
3. 2-bit error check: Double bit errors are induced sequentially and then checked for the expected uncorrectable error.

Figure 5-6. ECC Self-Test Sequence

If any of these checks fails, then self-test execution is aborted. The SELFTEST_DIAG_STATUS register can be read to check for these errors.

Refer to the following programming sequence for using the self-test controller:

1. Enable self-test controller (SELFTEST_DIAG_CONTROL. DIAG_TEST_EN = 0x11).
2. Write the input data pattern to be used for self-test
 - a. Write input pattern to SELFTEST_DIAG_DATAx registers with a data width of 52 bits.
3. Write the ECC pattern to SELFTEST_DIAG_ECC.
4. Execute ECCSELFTEST instruction.
5. Check for errors. If errors are found, take corrective action:
 - a. SELFTEST_DIAG_STATUS.DIAG_FAIL_CHECK_TYPE can be read to determine the sequence that was failed (Positive check, Correctable error check, or Uncorrectable error check).
 - b. SELFTEST_DIAG_STATUS.DIAG_FAIL_BIT_INDEX can be read to determine the data bit that was failed with error injection.
6. Clear the self-test status by writing to SELFTEST_DIAG_STATUS_CLR.

Refer to the following programming sequence to inject error in the vector ECC checker:

1. Enable the memory ECC diagnostics by writing to the MEM_ECC_DIAG.MEM_SIC_DIAG_EN register. The user can now intentionally inject an error by altering a vector address without altering the corresponding ECC and check error reporting logic.
2. For generating a single-bit error (Correctable Interrupt Vector Error):
 - a. Write to the Interrupt Vector Address Register (INT_VECT_ADDR_y) or Interrupt Link Ownership Config Register (INT_LINK_OWNER_y) so that only one bit is different from the existing configuration.
 - b. Read the written configuration.
3. For generating a double-bit error (Uncorrectable Interrupt Vector Error):
 - a. Write to the Interrupt Vector Address Register (INT_VECT_ADDR_y) or Interrupt Link Ownership Config Register (INT_LINK_OWNER_y) so that two or more bits are different from the existing configuration.
 - b. Read the written configuration.
4. The error gets notified to the ESM through Error Aggregator accordingly. In addition, the ESM can be configured by the user to generate an interrupt for a correctable error and NMI for an uncorrectable error.

Refer to the following programming sequence to inject error in the MMR parity checker:

1. Write to the REG_PARITY_DIAG_DATA.DIAG_DATA register with the desired data pattern and/or Write to the REG_PARITY_DIAG_PARITY.DIAG_PARITY_DATA register with the corresponding parity data bits. The user can now intentionally inject parity error and check error reporting logic.
2. Write to the REG_PARITY_DIAG_ASSERT.DIAG_ASSERT to assert parity diagnostics.
3. The error gets notified to the ESM through Error Aggregator accordingly. In addition, the ESM can be configured by the user to generate an interrupt for the Register Parity Diagnostic Error and NMI for the Register Parity Error.

Refer to PIPE Self-Test registers for additional details.

5.7.2 INTERRUPT Examples

NOTE: These examples are located in the F29x SDK installation from ti.com at the following location:
f29h85x-sdk_X_XX_XX_XX/examples/driverlib/CORE_IF_MULTICORE/interrupt

Cloud access to these examples is available at the following link: [dev.ti.com F29x SDK Examples](https://dev.ti.com/F29x_SDK_Examples).

5.7.2.1 RTINT vs INT Latency example - SINGLE_CORE

FILE: interrupt_ex1_int_rtint_latency.c

This example demonstrates the interrupt latencies of INT and RTINT. This configures 2 CPU timer interrupts with following priorities.

- RTINT Threshold = 15
- Timer 0 Interrupt priority = 10 -> RTINT
- Timer 1 Interrupt priority = 20 -> INT

User can set the macro `ENABLE_FUNCTION_CALL_IN_ISR` to 1 to configure both the ISRs to invoke a function call, hence multiple core registers needs to be saved and restored. If the macro is set to 0, both ISRs just updates a counter variable, hence requires only 1 register to be saved and restored. In case of RTINT, register saves and restores are done by the hardware. In case of INT, register saves and restores are done by the software.

The ERAD module is configured to measure the cycles taken between the timer interrupt event to the first instruction in the ISR.

Note : Run the example for some duration to get the min and max values. The watch variables are arrays with min and max values [Min, Max]

External Connections

- None

Watch Variables

- timer0_intEvent_to_isr : Min and Max cycles count between the timer event to the ISR entry
- timer0_isr_to_data : Min and Max cycle count between the ISR entry to the first C instruction (data access to cpuTimer0IntCount variable)
- timer1_intEvent_to_isr : Min and Max cycles count between the timer event to the ISR entry
- timer1_isr_to_data : Min and Max cycle count between the ISR entry to the first C instruction (data access to cpuTimer1IntCount variable)

Expected results : (With opt level = 1)

| RTINT | RTINT | INT | INT |

| w/o func | with func | w/o func | with func |

intEvent_to_isr | 23-29 | 23-29 | 21-27 | 21-27 |

isr_to_data | 1 | 1 | 2 | 25-26 |

5.7.2.2 INT and RTINT Nesting Example - SINGLE_CORE

FILE: interrupt_ex2_int_rtint_nesting.c

This example showcases nesting of INTs and RTINTs in groups using software interrupts and increments every time the software asserts an interrupt. The watch variables and print statements can be used to determine entry and exit points of ISR.

The interrupt priorities / group mask are configured as follows :

- RTINT Threshold = 20
- Group Mask = 0xFE
- INT 1 Interrupt priority = 50 -> INT (Group 24)
- INT 2 Interrupt priority = 51 -> INT (Group 24)
- INT 3 Interrupt priority = 49 -> INT (Group 23)
- RTINT 1 Interrupt priority = 10 -> RTINT (Group 4)
- RTINT 2 Interrupt priority = 11 -> RTINT (Group 4)
- RTINT 3 Interrupt priority = 9 -> RTINT (Group 3)

Order of Interrupt Triggers: INT1 -> INT2 -> INT3 -> RTINT1 -> RTINT2 -> RTINT3

Order of Interrupt Execution: INT1 -> INT3 -> RTINT1 -> RTINT3 -> RTINT1 -> RTINT2 -> INT3 -> INT1 -> INT2

Sysconfig inserts the required attributes to the ISR functions to inform the compiler that the function is an interrupt / realtime interrupt.

External Connections

- None

Watch Variables

- SWINT1Count - INT1 count
- SWINT2Count - INT2 count
- SWINT3Count - INT3 count
- SWINT4Count - RTINT1 count
- SWINT5Count - RTINT2 count
- SWINT6Count - RTINT3 count

5.7.2.3 RTINT Nesting limit - SINGLE_CORE

FILE: interrupt_ex3_rtint_nesting_limit.c

This example showcases the nesting limit of RTINTs using software interrupts. The watch variables and print statements can be used to determine entry and exit points of ISR. Note that the interrupts do not nest beyond the set limit.

The interrupt priorities are configured as follows :

- RTINT Threshold = 15
- RTINT Stack Pointer Warning Level = 3
- RTINT 1 Interrupt priority = 10
- RTINT 2 Interrupt priority = 9
- RTINT 3 Interrupt priority = 8
- RTINT 4 Interrupt priority = 7
- RTINT 5 Interrupt priority = 6

Order of Interrupt Triggers: RTINT1 -> RTINT2 -> RTINT3 -> RTINT4 -> RTINT5

Sysconfig inserts the required attributes to the ISR functions to inform the compiler that the function is a realtime interrupt.

External Connections

- None

Watch Variables

- *mySWINTCount.SWINT1* - RTINT1 count
- *mySWINTCount.SWINT2* - RTINT2 count
- *mySWINTCount.SWINT3* - RTINT3 count
- *mySWINTCount.SWINT4* - RTINT4 count
- *mySWINTCount.SWINT5* - RTINT5 count

5.8 PIPE Registers

This section describes the PIPE Registers.

5.8.1 PIPE Base Address Table

Table 5-9. PIPE Base Address Table

Structure	DriverLib Name	Base Address	Frame Applicable	CPU1	CPU2	CPU3	RTDMA1	RTDMA2	HSM	Pipeline Protected
PIPE_REGS	PIPE_BASE	0x3002_0000	-	YES	YES	YES	-	-	-	YES

5.8.2 PIPE_REGS Registers

Table 5-10 lists the memory-mapped registers for the PIPE_REGS registers. All register offset addresses not listed in Table 5-10 should be considered as reserved locations and the register contents should not be modified.

Table 5-10. PIPE_REGS Registers

Offset	Acronym	Register Name	Protection
0h	RTINT_THRESHOLD	Interrupt threshold register	SROOT_LINK_RW, BOOT_LINK_RW: BOOT_LINK_CTRL. BOOT_LINK_LOCK, LOCK: LOCK.GLOBAL_LO CK,, PARITY
4h	INT_GRP_MASK	Interrupt group mask register	SROOT_LINK_RW, BOOT_LINK_RW: BOOT_LINK_CTRL. BOOT_LINK_LOCK, LOCK: LOCK.GLOBAL_LO CK, PARITY

Table 5-10. PIPE_REGS Registers (continued)

Offset	Acronym	Register Name	Protection
802Ch	SELFTEST_DIAG_STATUS	Diagnostic status register	SROOT_LINK_RW, BOOT_LINK_RW: BOOT_LINK_CTRL. BOOT_LINK_LOCK
8030h	SELFTEST_DIAG_STATUS_CLR	Diagnostic status clear register	SROOT_LINK_RW, BOOT_LINK_RW: BOOT_LINK_CTRL. BOOT_LINK_LOCK

Complex bit access types are encoded to fit into small table cells. [Table 5-11](#) shows the codes that are used for access types in this section.

Table 5-11. PIPE_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
WOnce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

5.8.2.1 RTINT_THRESHOLD Register (Offset = 0h) [Reset = 00000000h]

RTINT_THRESHOLD is shown in [Figure 5-7](#) and described in [Table 5-12](#).

Return to the [Summary Table](#).

Interrupt threshold register

RESERVED								INT_GRP_MASK							
R-0h								R/W-FFh							

Table 5-13. INT_GRP_MASK Register Field Descriptions

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	Reserved
7-0	INT_GRP_MASK	R/W	FFh	Interrupt group mask bits. 0xFF: All interrupts can nest in one another. All interrupt levels are in individual groups, so 256 configurable priorities are available with 1 interrupt level in each. 0xFE: 128 priority groups with 2 interrupt levels in each, hence the number of priorities reduce to 128 for preemption. 0xFC: 64 priority groups with 4 interrupt levels in each, hence the number of priorities reduce to 64 for preemption. 0xF8: 32 priority groups with 8 interrupt levels in each, hence the number of priorities reduce to 32 for preemption. 0xF0: 16 priority groups with 16 interrupt levels in each, hence the number of priorities reduce to 16 for preemption. 0xE0: 8 priority groups with 32 interrupt levels in each, hence the number of priorities reduce to 8 for preemption. 0xC0: 4 priority groups with 64 interrupt levels in each, hence the number of priorities reduce to 4 for preemption. 0x80: 2 priority groups with 128 interrupt levels in each, hence the number of priorities reduce to 2 for preemption. 0x00: No interrupts can nest in one another. All interrupt levels are in one group, so configurable priorities are used for the highest priority interrupt. There is no nesting of interrupt levels regardless of INT or RTINT status. All other values: If any other value is used, the mask value defaults to 0xFF which correlates to no group mask. Reset type: SYSRStn

5.8.2.3 GLOBAL_EN Register (Offset = 8h) [Reset = 00000000h]

GLOBAL_EN is shown in [Figure 5-9](#) and described in [Table 5-14](#).

Return to the [Summary Table](#).

Global enable for INT and RTINT

This chapter describes the features and operation of the error aggregator module. The error aggregator is an interface module that aggregates and stores error information needed for critical errors in the device. The aggregated error output is passed on to ESM (Error Signalling Module) to take appropriate/configurable action on the error occurrence.

6.1 Introduction

Error aggregator is an interface module between ESM (Error Signaling Module) and peripherals that generate various errors like C29x, RTDMA, Memory controllers, Peripheral bridges, Read Interfaces. The main purpose of the Error Aggregator is to accumulate various errors from various sources and provide aggregated error output to ESM module. The module also logs the error status, error address, and error type information while segregating high-priority errors and low-priority errors for ESM to generate appropriate action to alert the CPU.

6.2 Error Aggregator Modules

Each Error Source provides the following information for all Error Aggregator Modules:

- Error - Pulse signal is generated on the occurrence of any error sent to ESM for further action.
- Error Address - System Address at which the error occurred used to detect and debug the error origin.
- Error Type - Multibit signal that indicates the type of error used to classify the error into predefined categories outlined later in the chapter.

All CPU Error Aggregator Modules additionally provide a Program Counter (PC) log for first high-priority error occurrence.

Figure 6-1 illustrates the module working and implementation. Each Aggregator module aggregates an error from various sources. Upon error occurrence, the corresponding error address and type are logged into the error address and error type registers, respectively.

The errors are classified as high or low priority based on the list in Section 6.6.

Figure 6-1. Error Aggregator Block Diagram

Error Aggregator modules implemented in the device are:

1. CPUx PR Error Aggregator - Aggregates errors occurred during CPUx program fetch access
2. CPUx DR1 Error Aggregator - Aggregates errors occurred during CPUx Data Read access on DR1 port
3. CPUx DR2 Error Aggregator - Aggregates errors occurred during CPUx Data Read access on DR2 port
4. CPUx DW Error Aggregator - Aggregates errors occurred during CPUx data write access
5. CPUx INT Error Aggregator - Aggregates interrupt related errors from CPUx and associated PIPE module
6. RTDMAx DR Error Aggregator - Aggregates errors occurred during RTDMAx data read access
7. RTDMAx DW Error Aggregator - Aggregates errors occurred during RTDMAx data write access
8. SSU Error Aggregator - Aggregates errors sent out by SSU module

9. EtherCAT Error Aggregator - Aggregates errors occurred during EtherCAT memory access
10. HSM Error Aggregator - Aggregates errors sent out by HSM subsystem

Note

x indicates that each error aggregator is repeated per initiator instance. EtherCAT only provides error and error address information so error type is tied off to uncorrectable error (0x40).

6.3 Error Propagation Path from Source to CPU

Section 6.4 describes the device level error handling and propagation from source to CPU. Error events from the Error Aggregator combined with other device level error events are provided to the ESM (Error Signaling Module). Refer to the ESM Event Map table in Section 7.3.1 for the complete list of error sources. ESM consolidates the responses to the error events and combined with other device level interrupt sources are sent to PIPE. For complete list of interrupts sent to the PIPE module, refer to the *PIPE Channel Mapping* table in Section 5.5.2.2. Optionally, the error events can be configured to signal error pin output, trigger reset to device or respective CPU depending on the application through ESM. Refer to Chapter 7 for more details.

Figure 6-2. Error Propagation Path from Source to CPU

6.4 Error Aggregator Interface

This section provides details on how error information is handled and interfaced to the Error Signaling Module (ESM). The error outputs from multiple error aggregators are ORed and applied as single source to ESM. These includes:

- Low-Priority Errors from CPUx PR, CPUx DR1, CPUx DR2, CPUx DW are combined as CPUx LPERR

- High-Priority Errors from CPUx PR, CPUx DR1, CPUx DR2, CPUx DW are combined as CPUx HPERR
- Low-Priority Errors from RTDMAx DR + RTDMAx DW are combined as RTDMAx LPERR
- High-Priority Errors from RTDMAx DR + RTDMAx DW are combined as RTDMAx HPERR

Figure 6-3 shows a conceptual block diagram of the module functionality and how the output flag from each aggregator is combined as described in points above. The block diagram does not show all error aggregator modules available in the system, refer to the detailed list of supported error aggregators.

Figure 6-3. Error Aggregator Interface

6.4.1 Functional Description

The address at which the first error occurred and the corresponding error type are logged into the error address and error type registers, respectively. The errors are categorized into high- and low-priority errors.

Following actions are taken by the Error Aggregator on the occurrence of any high-priority error:

- Error type bit corresponding to the error occurred is set.
- High-Priority Error output pulse is generated.
- Address at which the first high-priority error occurred is latched to the High-Priority Error Address register. This register is not updated on further error occurrence until the high-priority errors in the error type register are cleared.
- On further occurrence of high-priority errors, the error type register continues to accumulate new errors but the error address register is not updated and no further high-priority error output pulses are generated until all the high-priority errors in the error type register are cleared.
- Additionally the user can also emulate or force an error condition by writing to the corresponding error_type in the ERROR_TYPE_FRC register.

Following actions are taken by the Error Aggregator on the occurrence of any low-priority error:

- Error type bit corresponding to the error occurred is set.
- Low-Priority Error output pulse is generated.
- Address at which the first low-priority error occurred is latched to the Low-Priority Error Address register. This register is not updated on further error occurrence until the low-priority errors in the error type register are cleared.
- On further occurrence of low-priority errors, the error type register continues to accumulate new errors but the error address register is not updated and no further low-priority error output pulses are generated until all the low-priority errors in the error type register are cleared.
- Additionally the user can also emulate or force an error condition by writing to the corresponding error_type in the ERROR_TYPE_FRC register.

The error type register is cleared by writing to the ERROR_TYPE_CLR register.

In addition to the above error aggregator logs, the program counter value at the time of occurrence of the first high-priority error is applicable to all CPUx (PR, DR1, DR2, DW, and INT) Error Aggregators only.

Note

The program counter value logged is not always a precise value. In some cases, the error address value is more precise than the program counter value.

6.5 Error Condition Handling User Guide

User's configure the NMI ISR which are output from ESM to do the following checks for errors passed on from Error Aggregator to the ESM:

1. Check the ESM Raw Status Register - Error Group N Event Raw Status/Set Register to check which events caused the error interrupt to trigger from ESM using the ESM Event Map.
2. If the error trigger is caused due to an error aggregator event mapped to ESM (Group 0 Events), then check the corresponding error aggregator Instance Type register.
 - a. For example: If the Error Event 0 (ErrorAggregator_CPU1_HPERR) is detected from ESM in Step 1, user configures ISR to check error aggregator registers - CPU1_PR_ERROR_TYPE, CPU1_DR1_ERROR_TYPE, CPU1_DR2_ERROR_TYPE and CPU1_DW_ERROR_TYPE to determine what type of error was detected and in which instance of the error aggregator.
3. From Step 2, when user knows the error type, to narrow down the location of error user reads the corresponding error address register and program counter register.
 - a. For example: If user finds out that the ILLEGAL_INSTRUCTION (Bit 10) in CPU1_PR_ERROR_TYPE is set, then user reads the corresponding CPU1_PR_HIGHPRIO_ERROR_ADDRESS register to find out the address at which the first high-priority error occurred on CPU1_PR access.

- b. Also user reads CPU1_PR_PC register that contains the program counter value at the first high-priority error event.
4. While exiting the ISR, if user wants to clear the error when the source of the error is cleared - From Step 2, user stores the value of the error type register then copies the value to the error type clear register. If the source of the error still persists after the error clear, then the error aggregator generates another error pulse trigger to ESM.
 - a. For example: From Step 3, user stores the value from the CPU1_PR_ERROR_TYPE register and copies the same value to the CPU1_PR_ERROR_TYPE_CLR register to clear the CPU1_PR_ERROR_TYPE register.

Note

If user does not do step 4, the error aggregator does not generate another error event input to ESM until corresponding priority error type register is cleared.

When the application is not able to clear the error before a NMIWD (High Priority Watchdog) timeout, then a reset is triggered from ESMCPU1 instance (refer to [Figure 7-4](#)). In this case, after the reset has occurred due to NMIWD timeout, CPU1 starts running BootROM. Since the ESM raw status flags do not get reset (cleared) by XRSn, ESMCPU1 instance triggers another NMI and enters BootROM NMI ISR where errors (Error Aggregator type and ESM raw status registers) are cleared to avoid a back-to-back NMIWD reset loop and stores the error information and status to M0 RAM (refer to [Table 3-36](#)) for further debug.

In above case, BootROM clears the following status:

1. ESM Group0 RAW Status for ESMCPU1 and SYSESM instances of ESM-Subsystem
2. All CPUn error aggregator type registers

Also saves the following in M0 RAM for user to debug the source of error:

1. ESM RAW Status for Group0 only
2. Error Aggregator CPU1 - PR, DR1/2, DW, and INT instances error information including high-priority error address, low-priority error address, error type, and program counter registers

Due to above explained scenario, users are recommended to configure and setup proper NMI ISR as outlined in this section to avoid triggering NMIWD reset. For more information refer to - [Application Note - F29x Error Handling and Debug Guide](#).

6.6 Error Type Information

This section lists the error type information and associated priority for all error aggregators.

Table 6-1. Errors on CPUn PR Interfaces

Error Type	CPUn PR Error	RAM, ROM, FRI – PR Error	Priority
0x01	Instruction fetch security violation. Instruction packet crossed LINK, STACK, ZONE boundary. Linear code crossed LINK, STACK, ZONE boundary. Regular Branch and Calls crossed STACK, ZONE boundary.	Reserved	High

6.7 Error Sources Information

This section lists all the error sources for each of the aggregators.

Table 6-7. Sources to CPUx Program Read (PR) Error Aggregator

Sources to CPUx PR Error Aggregator	Comments
CPUx	From respective CPU
CPUx ROM Controller	From respective ROM controller
FRI	CPU1-FRI1, CPU3-FRI2
LDA SRAM (LDA0-7)	Applicable to CPU1 and CPU2 only
LPA SRAM (LPA0-1)	Applicable to CPU1 and CPU2 only
CPA SRAM (CPA0-1)	Applicable to CPU1 and CPU3 only
CDA SRAM (CDA0-11)	Applicable to CPU1 and CPU3 only

Table 6-8. Sources to CPUx Data Read on Port 1/Port 2 (DR1/DR2) Error Aggregator

Sources to CPUx DR1/DR2 Error Aggregator	Comments
CPUx	From respective CPU
CPUx ROM Controller	From respective ROM Controller
FRI	Applicable to CPU1 and CPU3 only
M0	Applicable to CPU1 and CPU2 only
LDA SRAM (LDA0-7)	Applicable to CPU1 and CPU2 only
LPA SRAM (LPA0-1)	Applicable to CPU1 and CPU2 only
CPA SRAM (CPA0-1)	Applicable to CPU1 and CPU3 only
CDA SRAM (CDA0-11)	Applicable to CPU1 and CPU3 only
GAB1	Applicable to CPU3 only
GAB2	Applicable to CPU2 only
VBUSP_CPUx	From respective VBUSP_CPUx bridge
VBUSP_SSU	Applicable to CPU1-3
VBUSP_PROG	Applicable to CPU1 and CPU3 only
VBUS32_CONFIG	Applicable to CPU1-3
VBUSP_CONFIG	Applicable to CPU1-3
VBUS32_AP_CPUx	From respective VBUS32_AP_CPUx bridge
ADCWRAPPER	Applicable to CPU1-3
SOC_TO_HSM_Bridge	Applicable to CPU1-3
VBUSP_ETHERCAT	Applicable to CPU1-3

Table 6-8. Sources to CPUx Data Read on Port 1/Port 2 (DR1/DR2) Error Aggregator (continued)

Sources to CPUx DR1/DR2 Error Aggregator	Comments
VBUS32_ETHERCAT	Applicable to CPU1-3
PDI_ETHERCAT	Applicable to CPU1-3
VBUSP_frame0	Applicable to CPU1-3
VBUSP_frame1	Applicable to CPU1-3
VBUSP_frame2	Applicable to CPU1-3
VBUSP_frame3	Applicable to CPU1-3
VBUS32_frame0	Applicable to CPU1-3
VBUS32_frame1	Applicable to CPU1-3
VBUS32_frame2	Applicable to CPU1-3
VBUS32_frame3	Applicable to CPU1-3
VBUSP_EMIF	Applicable to CPU1-3
Data line buffer (DLB)	From respective CPU DLB

Table 6-9. Sources to CPUx DW (Data Write) Error Aggregator

Sources to CPUx DW Error Aggregator	Comments
CPUx	From respective CPU
M0	Applicable to CPU1 only
LDA SRAM (LDA0-7)	Applicable to CPU1 and CPU2 only
LPA SRAM (LPA0-1)	Applicable to CPU1 and CPU2 only
CPA SRAM (CPA0-1)	Applicable to CPU1 and CPU3 only
CDA SRAM (CDA0-11)	Applicable to CPU1 and CPU3 only
GAB1	Applicable to CPU3 only
GAB2	Applicable to CPU2 only
VBUSP_CPUx	From respective VBUSP_CPUx bridge
VBUSP_SSU	Applicable to CPU1-3
VBUSP_PROG	Applicable to CPU1 and CPU3 only
VBUS32_CONFIG	Applicable to CPU1-3
VBUSP_CONFIG	Applicable to CPU1-3
VBUS32_AP_CPUx	From respective VBUS32_AP_CPUx bridge
SOC_TO_HSM_Bridge	Applicable to CPU1-3
VBUSP_ETHERCAT	Applicable to CPU1-3
VBUS32_ETHERCAT	Applicable to CPU1-3
PDI_ETHERCAT	Applicable to CPU1-3
VBUSP_frame0	Applicable to CPU1-3
VBUSP_frame1	Applicable to CPU1-3
VBUSP_frame2	Applicable to CPU1-3
VBUSP_frame3	Applicable to CPU1-3
VBUS32_frame0	Applicable to CPU1-3
VBUS32_frame1	Applicable to CPU1-3
VBUS32_frame2	Applicable to CPU1-3
VBUS32_frame3	Applicable to CPU1-3
VBUSP_EMIF	Applicable to CPU1-3

6.9 ERRORAGGREGATOR Registers

This Section describes the ERRORAGGREGATOR Registers.

6.9.1 ERRORAGGREGATOR Base Address Table

Table 6-16. ERRORAGGREGATOR Base Address Table

Structure	DriverLib Name	Base Address	Frame Applicable	CPU1	CPU2	CPU3	RTDMA1	RTDMA2	HSM	Pipeline Protected
HSM_ERROR_AGGREGATOR_CONFIG_REGS	HSMERRORAGGREGATOR_BASE	0x3012_0000	-	-	-	-	-	-	YES	YES
ERROR_AGGREGATOR_CONFIG_REGS	ERRORAGGREGATOR_BASE	0x6008_C000	YES	YES	YES	YES	YES	YES	-	YES

6.9.2 HSM_ERROR_AGGREGATOR_CONFIG_REGS Registers

Table 6-17 lists the memory-mapped registers for the HSM_ERROR_AGGREGATOR_CONFIG_REGS registers. All register offset addresses not listed in Table 6-17 should be considered as reserved locations and the register contents should not be modified.

Table 6-17. HSM_ERROR_AGGREGATOR_CONFIG_REGS Registers

Offset	Acronym	Register Name	Protection
0h	HSM_HIGHPRIO_ERROR_ADDRESS	High Priority Error address register	
4h	HSM_LOWPRIOR_ERROR_ADDRESS	Low Priority Error address register	
8h	HSM_ERROR_TYPE	Error Type Register	
Ch	HSM_ERROR_TYPE_FRC	Error Type Force Register	
10h	HSM_ERROR_TYPE_CLR	Error Type Clear Register	

Complex bit access types are encoded to fit into small table cells. Table 6-18 shows the codes that are used for access types in this section.

Table 6-18. HSM_ERROR_AGGREGATOR_CONFIG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

6.9.2.1 HSM_HIGHPRIO_ERROR_ADDRESS Register (Offset = 0h) [Reset = 00000000h]

HSM_HIGHPRIO_ERROR_ADDRESS is shown in [Figure 6-4](#) and described in [Table 6-19](#).

Return to the [Summary Table](#).

High Priority Error address register

Figure 6-4. HSM_HIGHPRIO_ERROR_ADDRESS Register

6.9.3 ERROR_AGGREGATOR_CONFIG_REGS Registers

Table 6-24 lists the memory-mapped registers for the ERROR_AGGREGATOR_CONFIG_REGS registers. All register offset addresses not listed in Table 6-24 should be considered as reserved locations and the register contents should not be modified.

Table 6-24. ERROR_AGGREGATOR_CONFIG_REGS Registers

Offset	Acronym	Register Name	Protection
0h	CPU1_PR_HIGHPRIO_ERROR_ADDRES S	CPU1 PR Error aggregator High Priority Error address register	
4h	CPU1_PR_LOWPRIO_ERROR_ADDRES S	CPU1 PR Error aggregator Low Priority Error address register	
8h	CPU1_PR_ERROR_TYPE	CPU1 PR Error aggregator Error Type Register	
Ch	CPU1_PR_ERROR_TYPE_FRC	CPU1 PR Error aggregator Error Type Force Register

Complex bit access types are encoded to fit into small table cells. [Table 6-25](#) shows the codes that are used for access types in this section.

Table 6-25. ERROR_AGGREGATOR_CONFIG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		

**Table 6-25. ERROR_AGGREGATOR_CONFIG_REGS Access Type Codes
(continued)**

Access Type	Code	Description
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

6.9.3.1 CPU1_PR_HIGHPRIO_ERROR_ADDRESS Register (Offset = 0h) [Reset = 00000000h]

CPU1_PR_HIGHPRIO_ERROR_ADDRESS is shown in [Figure 6-9](#) and described in [Table 6-26](#).

Chapter 7

Error Signaling Module (ESM_C29)

This chapter describes the features and operation of the error signaling module (ESM_C29) module.

7.1 Introduction.....	1097
7.2 ESM Subsystem.....	1098
7.3 ESM Functional Description.....	1104
7.4 ESM Configuration Guide.....	1128
7.5 Interrupt Condition Control and Handling.....	1130
7.6 Software.....	1133
7.7 ESM Registers.....	1139

7.1 Introduction

The Error Signaling Module (ESM) provides systematic consolidation of responses to error events throughout the device into one location. The ESM can signal programmable priority interrupts to the processor to deal with an event and/or manipulate an I/O error pin to signal an external hardware that an error has occurred. Therefore, an external controller is able to reset the device or keep the system in a safe, known state.

The ESM provides comprehensive error reporting and consolidates error responses for management and mitigation of error events across the device.

Figure 7-1. Error Handling Architecture

7.1.1 Features

The following points highlight the main features of the Error Signaling Module (ESM) Subsystem:

- ESM Subsystem consists of three ESM CPU Instances (one for each CPU), a single System ESM (SYS ESM) for Error Pin Output and Monitoring, and an additional Safety Aggregator (ESM Register Parity Error Aggregator) Instance for Register Parity Error Aggregation for all ESM instances (ESM CPU and System ESM).
- Supports up to 256 error event inputs: Error events from Error Aggregator and System level fault event sources are mapped to ESM subsystem and applied to all ESM instances (Refer to [Section 7.3.1](#) for more details)
 - Divided in groups of 32 error events (Total 8 Groups)
- Selectable Low- and High-Priority Interrupt prioritization of each error event for each ESM CPU instance
- Critical-Priority and High-Priority Watchdog Interrupt outputs for each ESM CPU instance
 - Pulse type output only
- System ESM Instance to signal severe device failure produces an Error Pin Output in addition to set of interrupt outputs
 - Supports of level or PWM modes for error pin output
 - Error Pin Monitoring
- Configurable timebase for error pin signal output
- Error forcing capability
- Parity Detection and Commit/Lock for MMRs

7.1.2 ESM Related Collateral

7.2 ESM Subsystem

The Error Signaling Module Subsystem (ESM-SS) groups error signaling module (ESM) instances as shown in [Figure 7-2](#). ESMSS supports a number of ESM instances that is triggered from common set of error event inputs. Each ESM instance is used to drive interrupts to individual CPU and resets to individual CPU or System. The subsystem combines the ESM instances and output pulse interrupt from each ESM instances are exported at the subsystem boundary for integration at the device level.

ESM subsystem is comprised of the following instances:

- ESM CPU instances one for each CPU
 - **Input's:** The error inputs listed in [Section 7.3.1](#), common to all ESM Subsystem instances
 - **Output's:**
 - Low-Priority Interrupt
 - High-Priority Interrupt
 - High-Priority WD Event (event triggered by a watchdog timeout on a High-Priority Interrupt; hence, also referred to as a High-Priority Watchdog Interrupt in this document). Similar functionality as NMIWD on C28x devices.
 - Critical-Priority Interrupt
- Additional System ESM instance for Error Pin output and monitoring.
 - **Input's:** The error inputs listed in [Section 7.3.1](#), common to all ESM Subsystem instances
 - **Output's:**
 - Low-Priority Interrupt
 - Critical-Priority Interrupt
 - Error Pin Output
 - Error Pin Monitor Event: Error pin monitoring and error detection output
- Register Parity Error Aggregator Instance (Safety Aggregator)
 - **Input's:**
 - Input from EDC (Error Detection and Correction) Control Interfaces of all ESM Instances (ESM CPU and SYS ESM)
 - **Output:**
 - Parity Error Interrupt: Interrupt generated by parity error detected on ESM register configurations

Figure 7-2. ESM-SS Block Diagram

7.2.1 System ESM

Error Pin inputs and outputs are controlled by System ESM instance. The System ESM produces an configurable error pin output (err_o/ERRORSTS) in addition to the set of interrupt outputs. The System ESM generates a critical priority interrupt (ESMRESET) output that causes system reset request (XRSn) by default, if not disabled by the ESMXRSNCTL register. The System ESM additionally has the Error Pin Monitor feature and associated Error Pin Monitor event that is exported at subsystem as a pulse interrupt. Error Pin Monitor event is also applied back to ESM-SS as an error event input so that the ESM can take appropriate action on the mismatch event.

The low-priority interrupt output of System ESM is mapped to the XBARS as an ESMGENEVT signal.

7.2.1.1 Error Pin Monitor Event

The error pin monitor event indicates that the err_i and err_o pins (input and output to the ESM, respectively) have differed for eight or more consecutive cycles. This detects if the error pin connectivity external to the ESM is malfunctioning.

ERR_I is stored, in case previous values of ERR_I are either all 0s or 1s, the previous 8 values of ERR_O is checked for at least one match. If there is no match between the previous 8 values of ERR_I and ERR_O, this indicates that the external connection from ERR_O back to ERR_I is malfunctioning. Error Pin Monitor event/interrupt is triggered only if all values of ERR_I being equal (all 0s or 1s) and stored ERR_O values being the logical inverse (all 0s or 1s). The above mechanism provides immunity against glitches or pin transitions triggering spurious pin monitor interrupt outputs. PWM low and high counters values need to be greater than 8 cycles when using pwm mode for error pin monitoring to detect a malfunctioning ERR_I.

When an error pin monitor interrupt occurs, a processor handling this interrupt logs or alerts the external system associated with error pin monitoring. This interrupt can be enabled/disabled using the Error Pin Monitor Configuration Register and set or cleared using the Error Pin Monitor Interrupt Status/Set Register and the Error Pin Monitor Interrupt Status/Clear Register, respectively.

A software write of the EOI vector to the EOI Interrupt Register also results in a re-evaluation of the error pin monitor interrupt/event.

7.2.2 Safety Aggregator

The Safety Aggregator module is used within the ESM subsystem to aggregate all the error detection and correction (EDC) interfaces from each ESM instance. The ESM instances (including the System ESM instance) each has an EDC Controller to control parity detection logic and injection of errors for testing purposes.

7.2.2.1 EDC Controller Interface Description

Each ESM Instance has a EDC (Error detection and Correction) control interface which works with Safety aggregator for parity error detection of all ESM instance registers.

The safety aggregator module communicates to the individual ESM EDC instance through serial VBUS(svbus) protocol. EDC interface for each ESM instance receives command from safety aggregator through a serial vbus connection, the error status information can be accessed through the registers described in [Section 7.7.5](#). Sections below describe the read and write operation sequence to be followed by user for communication to respective ESM EDC interface using svbus protocol from safety aggregator.

Figure 7-3. Safety Aggregator Block Diagram

7.2.2.2 Read Operation on EDC Controller

User needs to follow the outlined steps for read transaction on serial VBUS initiated from safety aggregator to the respective ESM EDC controller:

1. Write Vector register `ecc_vector` field with the appropriate ID for respective ESM instance, address of EDC Controller register to `rd_svbus_address` field, and set `rd_svbus` field to a 1 to trigger a read on the serial VBUS.
2. Poll Vector register until `rd_svbus_done` (bit 24) is 1.
3. Check for Vector register field `rd_svbus_done` = 1 (if set to one). Once the `rd_svbus_done` is set user can do a read of the `reserved_svbus_y` register (`ESM_SAFETYAGG_REGS + 0x10`) in the safety aggregator address space, this returns the read value of the address entered to `rd_svbus_address` field in step1. The read of the register data is available only at first location of `reserved_svbus_y` register (`ESM_SAFETYAGG_REGS + 0x10`).

7.2.2.3 Write Operation on EDC Controller

User needs to follow the outlined steps for write transaction on serial VBUS initiated from safety aggregator to respective ESM EDC controller instance:

1. Write Vector register with the appropriate ID for the ESM instance selected for write operation to `ecc_vector` field (bits 10-0), make sure `rd_svbus` field is set to zero. Read address is a don't care.
2. After step1, user writes to the `reserved_svbus_y` register space in the safety aggregator address space whose offset is same as the `EDC_REGS` interface for the specific ESM EDC controller instance selected in Step1 with vector register `ecc_vector` field write. `EDC_REGS` interface for selected ESM EDC maps to Safety aggregator `reserved_svbus_y` register space when doing write operation.
 - a. For example, `EDC_REGS.CONTROL` register write address space maps to `ESMSAFETYAGG_BASE + 0x14` address which is the part of `reserved_svbus_y` register space in safety aggregator.

7.2.2.4 Safety Aggregator Error Injection

User needs to follow the outlined steps for parity error injection using serial VBUS:

1. Write Vector register (offset - 0x8) with the index of the EDC controller to vector ID (bits 10-0), make sure `rd_svbus` = 0.
2. Write to Error 1 register (offset - 0x18) of the EDC controller to program following:
 - a. The GRP (group of checker to inject).
 - b. The bit location that is to be flipped.
3. Write Control register (offset - 0x14) of the EDC controller to start the injection with the following:
 - a. Make sure `CHECK` field (bit 1) is enabled.
 - b. Set `force_se` (bit 3) for single-bit error to trigger parity error.
4. When an interrupt from the safety aggregator is detected (assuming interrupts are enabled), software can read the raw interrupt status registers `DED_STATUS_REG0` and check which ESM EDC controller has parity error.
5. To further find out information about the checker that detects the error, follow this sequence:
 - a. Do a read operation from the ESM EDC Controller to read `ERROR STATUS 1` register (offset - 0x20).
 - b. From Error Status 1 register - user can check which specific checker reported the error and how many injected and non-injected errors are pending.
6. User can then do a Write operation to Error Status 1 register to clear injected error while exiting the parity error interrupt ISR and write the EOI register to acknowledge future error interrupts.

7.2.3 ESM Subsystem Integration View

The subsystem interacts with multiple blocks at the device level. The key ones being sources of errors, CPU's, Interrupt modules, System Control modules, and I/O pin interfaces. User can configure the controls and access various states of errors and actions. Subsystem consolidates various error sources and captures them to

determine the right action based on user configurations. [Table 7-1](#) outlines the respective ESM instance output mapping at device level. [Figure 7-4](#) describes how the subsystem integrates at the device level in detail.

Table 7-1. ESM Output Mapping

ESM Interrupt Output	ESM Output Connection to PIPE	ESM Instance	Error Response to the Device
Low-Priority Interrupt	Interrupt Line	ESM CPU1	CPU1 - INT/ RTINT (configurable in PIPE)
		ESM CPU2	CPU2 - INT/ RTINT (configurable in PIPE)
		ESM CPU3	CPU3 - INT/ RTINT (configurable in PIPE)
		System ESM	XBAR Event (See XBAR chapter for ESM_GEN_EVENT input mapping)
High-Priority Interrupt	NMI Line	ESM CPU1	CPU1 NMI
		ESM CPU2	CPU2 NMI
		ESM CPU3	CPU3 NMI
High-Priority Watchdog Event/ High-Priority Watchdog Interrupt	-	ESM CPU1	XRSn (Device Reset)
		ESM CPU2	CPU2RSn or XRSn (only if enabled in ESMXRSNCTL register)
		ESM CPU3	CPU3RSn or XRSn (only if enabled in ESMXRSNCTL register)
Critical-Priority Event	-	ESM CPU1	XRSn (Device Reset)
		ESM CPU2	XRSn (only if enabled in ESMXRSNCTL register)
		ESM CPU3	XRSn (only if enabled in ESMXRSNCTL register)
		System ESM	XRSn (Device Reset)

Figure 7-4. ESM Subsystem Integration View

7.3 ESM Functional Description

Figure 7-5 and Figure 7-6 illustrates the module features and functionality. The Error Signaling Module (ESM) centralizes fault reports and provides mechanisms to classify errors by severity and to provide programmable error response. The error classification in the ESM is determined by programmed configuration for each individual error input. For each individual error input the configuration can be set to assert an output error pin, or generate an interrupt to a CPU, or both. When an individual error input is configured to generate an interrupt, the configuration also selects whether the interrupt that is generated is high priority or low priority.

Figure 7-5. ESM CPU Block Diagram

Figure 7-6. System ESM Block Diagram

By reporting the faults in a central location, the system can determine what caused the fault and what action can be taken. In general the faults can be split into two categories:

- Corrected faults
- Non-corrected faults

The ESM reports errors in two ways:

- An interrupt to a processor in the device. This allows the device to analyze and try to recover from an error.
- An external ERROR pin for System ESM module. This allows the system outside of the device to monitor for potentially fatal errors (errors that the device cannot self-recover from). Moreover, the external I/O (ERROR pin) can operate in level or PWM modes. In level mode, the output remains asserted (active low) for a minimum period of time. After that period of time, if the error has been cleared by an internal processor, the pin goes inactive (high). If signal does not go inactive in that time, then an external agent must intervene, as an unrecoverable error can occur. In PWM mode, the error causes the output pin to maintain the value for a minimum period of time. After that period of time, if the error has been cleared by an internal processor, the pin continues the PWM pattern. If the signal does not go inactive in that time, then an external agent must intervene, as an unrecoverable error can occur.

Both mechanisms can be used at the same time for the same fault, signaling both an interrupt and the external ERROR pin. This allows the device to attempt to recover, but if recovery fails, then the external system is still alerted. If recovery succeeds, then the ERROR pin assertion can be removed so that the external system knows that a potentially unsafe condition was avoided.

Lastly, the ESM does not specify any methods of intervention, only the process of alerting internal CPUs and external monitors of an existing error event.

7.3.1 Error Event Inputs

Single ESM module supports up to 256 error event inputs, configurable by groups of 32. Error event inputs type can be either level or pulse. N (0-31) is the total number of groups, and X is the number of groups that are pulse. For this device, $N=X$ means there are only pulse events and no level events. All events are relative to 0; hence, Event Group 0 Event 0 is global event 0 and sequentially Event Group1 Event 0 is global event 32.

Global event 0 to 31 are part of *Group0* similarly global event 32 to 63 belong to *Group1* and so on.

The pulse error event has a dedicated rising-edge detection circuit for each input.

Input Error Event Mapping to ESM is captured in [Table 7-2](#).

Note

All Error Events that cause CPU to go into fault state must be configured to generate NMI (High-Priority Interrupt) only. Group 0 events (Event Number 0 to 31) are mapped to High-Priority Interrupt by default. CPUx_TMUROM_PAR_ERR also must be configured to generate NMI (high-priority interrupt) in ESM configurations at device initialization.

All error event inputs are Pulse type only for this device.

7.3.2 Error Interrupt Outputs

Each module generates an Interrupt Output so that the processor in the device is signaled to intervene when an Error Event occurs. Each error event input is to be enabled to cause an Error Interrupt to occur (using Error Group *N* Interrupt Enabled Set Register). Additionally, each error event input is configured to be programmed to influence either the low-priority (default) interrupt or the high-priority interrupt (using Error Group *N* Interrupt Priority Register). The low-priority interrupt is intended for events that are of interest, but does not require immediate intervention. For example, an indication that there was a single-bit error that was corrected can be configured to signal a low-priority interrupt, so that information can be collected for statistical purposes. A high-priority interrupt is intended for events that need immediate attention. For example, an indication that there was an uncorrected two-bit error can be configured to signal a high-priority interrupt.

7.3.2.1 High-Priority Watchdog

A High-Priority Watchdog can be enabled to monitor if the process associated with servicing the High-Priority Interrupt has failed to do so. Count down starts from a Pre-Load value and triggers the High-Priority Watchdog Interrupt when the time has expired. As long as at least one enabled error associated with the High-Priority Interrupt is outstanding, the Watchdog continues to count down.

The Watchdog only triggers the High-Priority Watchdog Interrupt a single time until and unless the Interrupt is cleared. The High-Priority Interrupt can be cleared with the High-Priority Watchdog Interrupt Status/Clear Register or by writing the EOI vector to the EOI Interrupt Register.

If the Watchdog value is non-zero and all High-Priority errors are cleared, the Watchdog timer resets to the Pre-Load value and waits until the next High-Priority error to begin counting down again.

An MMR write to the Pre-Load value overwrites the Watchdog counter value if the Watchdog is inactive. If the Watchdog is counting down, a write to the Pre-Load value does not have any effect until the Watchdog is once again inactive.

If the Pre-Load value is zero, a High-Priority Watchdog Interrupt is triggered when an error associated with the High-Priority Interrupt occurs.

Figure 7-7. High-Priority Watchdog Event Flowchart

7.3.2.2 Critical-Priority Interrupt Output

The ESM supports a third interrupt output for events that are deemed even more critical than high-priority events. For example, an error whose desired end result is a warm reset of a domain or the entire device. Unlike Low-/High-Priority Error Events, Critical-Priority Error Events do not require enabling using the Error Group *N* Interrupt Enabled Set Register. Instead, each Critical-Priority Error Event input is configured individually to influence the Critical-Priority Interrupt Output using the Error Group *N* Critical Priority Interrupt Influence Set Register.

The critical priority interrupt output is sensitive to the ESMs warm reset input as well as the Global Soft Reset MMR. The ESMs warm reset input is used synchronously and assertion of the ESM Warm Reset Input disables the ESM Global Enable MMR. When the critical priority interrupt output triggers, the occurrence is logged in the Info Register. The logging status is only reset using POR and the Global Soft Reset MMR.

7.3.3 Error Pin Output (ERR_O/ERRORSTS)

The error pin output (ERR_O/ERRORSTS) is used to signal an external agent to intervene because of an error. Each error event input can be programmed, using software, to influence the error pin output (using the Error Group *N* Error Pin Influence Set Register). The error pin output is active low or PWM based on the Error Pin Control Register[7-4] PWM_EN field. This bit field can only be modified when the ESM is disabled, based on the Global Enable register.

During Power-On Reset (POR), the error pin is active (asserted low) and the device drives this using a weak internal pull-down. The I/O is under the control of the device. When POR is removed from the ESM, error pin is driven by internal pull-down so the device can hand over control to the ESM. The user can also add an external pull-down that is only active when the device is in reset.

During a warm reset the state of the error pin is unchanged, that is the error pin logic is only reset by a POR. The device leaves the I/O active during a warm reset.

[Figure 7-8](#) describes the behavior of the Error Pin. Not shown is that a reset (Power-On-Reset only) immediately transitions the Error pin to the ESM_RESET state and a Global Soft Reset immediately transitions the Error pin to the ESM_IDLE state. A Pending Error Event is any error event with the raw state set and the Error Pin Influence enabled. There are two types of “clear” events associated with servicing the Error Pin. The first is to clear the status of the pending event (see [Section 7.5](#) for how to clear level and pulse pending events). The second is the CLEAR event meant to de-assert the Error Pin.

Figure 7-8. Error Pin State Flowchart

If an error event happens that has been programmed to influence the Error Pin, the Error Pin asserts (active low) for a minimum time as programmed (using the Error Pin Counter Pre-Load Register). For the Error Pin to de-assert, the following 3 things must happen : 1. The Minimum Time Interval must expire 2. The event that caused the Error Pin to assert must be cleared (see section for Interrupt Handling) 3. A CLEAR must be written to the Error Pin Control Register. Note that step 3 can only happen after step 2, but either (or both) of those steps can occur before or after step 1.

Figure 7-9 shows a typical error pin assertion.

Figure 7-9. ESM Error Pin Assertion

If, during the minimum time, CLEAR is written to the error key, then the error pin de-asserts after the minimum time interval, as shown in [Figure 7-10](#).

Figure 7-10. ESM Error Pin Assertion with CLEAR During Minimum Interval

If CLEAR is not written until after the Minimum Interval, the Error Pin de-asserts when CLEAR is written. This is regardless of whether the Error Event is removed before or after the Minimum Interval (as shown by the dotted line in [Figure 7-11](#)).

Figure 7-11. Error Pin Asserting with CLEAR after Minimum Interval

When in the ESM_ERROR state and a CLEAR event happens, if there are still pending Error Events, the ESM stays in the ESM_ERROR state with the Error Pin asserted. Multiple Error Events when in the ESM_ERROR state do not reset the Minimum Interval counter.

Figure 7-12. Error Pin Asserting with Interval Reset by Additional Error Event

A CLEAR event causes a re-evaluation of whether there are any pending Error Events. As such, a single CLEAR can be used to clear the Error Pin after multiple Error Events. Multiple CLEAR events can occur (such as the one with the dotted arrow in [Figure 7-13](#)), but are not necessary. No matter how many Error Events occur nor when (or how many) CLEAR events occur, the Error Pin is always asserted for at least the Minimum Interval.

Figure 7-13. Error Pin Asserting with Single CLEAR for Multiple Events

If all Error Events are cleared and the ESM is in the ESM_WAIT state, waiting for the Minimum Interval to expire, and a new Error Event occurs, the ESM goes back to the ESM_ERROR state. The Minimum Interval does not reset, but a new CLEAR event is required.

Figure 7-14. Error Pin Asserting with New Error During Minimum Time Interval

Table 7-3 shows some common scenarios of how the error pin as well as the two associated registers (Error Pin Control Register and Error Pin Status Register) are set.

Table 7-3. ESM Error Pin Scenarios

Scenario	Error Pin State Value	KEY	Error Pin Register Status	Additional Notes
POR Asserted	0	N/A	N/A	Registers are inaccessible. Device disables the I/O and pulls down internally.
After de-assertion of POR	1	0x0 (Normal Mode)	0x1	-
After de-assertion of Warm Reset (error was not asserted when reset asserted)	1	0x0 (Normal Mode)	0x1	-
After de-assertion of Warm Reset (error was asserted when reset asserted)	0	0x0 (Normal Mode)	0x0	-
Force error pin	0	0xA (Force Error Mode)	0x0	Forcing error on the pin using software.

7.3.3.1 Minimum Time Interval

The Minimum Time Interval is the minimum amount of time that the Error Pin remains asserted (active low) when an enabled Error Event occurs. This value is system dependent, but time interval must be high enough so that the external monitoring agent can always detect the Error Pin asserted, but short enough so that if all of the Error Events are cleared, then the Error Pin can be de-asserted before the external agent decides to intervene. This is highly dependent on the application and the Fault Tolerant Time Interval.

The Minimum Time Interval counter is clock cycle based, therefore the time of the interval is a combination of the value in the Error Pin Counter Pre-Load Register and the clock frequency of the ESM. For Software configuration the value must be calculated accordingly. The Minimum Time Interval default value is set to 0xFF FFFF (for both modes: level and pwm (high and low minimum time interval values)), although this value can be changed according to the needs of the application after start-up.

7.3.3.2 PWM Mode

If the error output pin is in PWM mode and when no error is detected pin toggles according to programmable MMR widths for high and low periods. When an error occurs, the error pin stops toggling and remains constant until the error is cleared. An external Power Management Integrated Circuits (PMIC) that is detecting the PWM toggles can identify the error if the pin stops toggling. The periods must be programmed considering the expectation of the external PMIC.

7.3.4 Reset Type Information for ESM Registers

Table 7-4. Reset Type Information

Register	Reset Domains		
	Module Reset	SFT_RST (Global Soft Reset)	PORESETn
INFO Register Bit 31			Yes
INFO Register Bit 30		Yes	Yes
EN (Global Enable)	Yes	Yes	Yes
LOW_PRI, HI_PRI, LOW, HI	Yes	Yes	Yes
HI_PRI_WD_CFG, HI_PRI_WD_CNTR, HI_PRI_WD_CNTR_PRE, HI_PRI_WD_INTR_SET, HI_PRI_WD_INTR_CLR	Yes	Yes	Yes
GROUP_N_LOCK, GROUP_N_COMMIT, ERR_PIN_INFLUENCE_LOCK, ERR_PIN_INFLUENCE_COMMIT, CRI_PRI_INFLUENCE_LOCK, CRI_PRI_INFLUENCE_COMMIT, MMR_CONFIG_LOCK, MMR_CONFIG_COMMIT	Yes	Yes	Yes
RAW_j, STS_j, INTR_EN_SET_j, INTR_EN_CLR_j, INT_PRIO_j, CRIT_EN_SET_j, CRIT_EN_CLR_j		Yes	Yes

Table 7-4. Reset Type Information (continued)

Register	Reset Domains		
	Module Reset	SFT_RST (Global Soft Reset)	PORESETn
PIN_CTRL, PIN_STS, PIN_CNTR, PIN_CNTR_PRE, PWMH_PIN_CNTR, PWMH_PIN_CNTR_PRE, PWML_PIN_CNTR, PWML_PIN_CNTR_PRE, ERRPIN_MON_CFG, ERRPIN_MON_INTR_SET, ERRPIN_MON_INTR_CLR		Yes	Yes
PIN_EN_SET_j, PIN_EN_CLR_j		Yes	Yes

Table 7-5. Module Reset Domain Information

ESM Subsystem Instance	Module Reset
ESM CPU1	CPU1SYSRSn
ESM CPU2	CPU2SYSRSn
ESM CPU3	CPU3SYSRSn
SYS ESM	XRSn

ESMCPU2 and ESMCPU3 instance only available after the respective CPU2 and CPU3 reset is released. If CPU2 is held in reset ESMCPU2 is not functional and same applies to ESMCPU3. Even when CPU2 is in lockstep with CPU1, ESMCPU2 instance is not available. If user wants to operate CPU2 as standalone core, lockstep needs to be disabled and then CPU2 reset needs to be released for ESMCPU2 instance to be functional. [Table 7-5](#) helps to explain the above.

SYS ESM and Safety Aggregator instances is always available for functional use case irrespective of CPU2 or CPU3 being held in reset.

7.3.5 Clock Stop

The ESM can only be put in to clock stop if all of the internal state machines are idle and the global_enable is cleared (using the Global Enable register).

7.3.6 Commit/Lock for MMRs

Lock/Commit feature allows the configured Enable bits for given errors to be locked to prevent further changes. To prevent changes, the Lock must be written, then the Commit. The Commit prevents the Lock from changing. Both Commit and Lock MMRs are reset by the warm reset (module reset) and by global soft reset.

When Lock is set to 1, the associated MMR values can not be changed. When Commit is set to 1, the Lock value can not be changed. Additionally, once set to 1, the Commit value can not be changed. Both Commit and Lock are reset by the warm reset (mod_g_rst_n) and by global soft reset.

All of the writeable MMRs have Commit/Lock bits except for the following:

- EOI Interrupt Register
- All of Status/Clear Registers
 - Error Group N Event Raw Status/Set Register
 - Error Group N Event Enabled Status/Clear Register

7.3.7 Safety Protection for MMRs

The configuration MMRs are backed by parity checker, with one bit of parity per 8 bits of MMR data.

The parity detection logic is controlled by an EDC Controller instance, which can also be used to inject errors for testing purposes. The EDC Controller from each ESM module works with Safety Aggregator instance as described in [Section 7.2.2.1](#).

7.3.8 Register Configuration Tieoffs

The ESM Modules have MMR tieoffs namely Group 0 High-Priority Tieoffs and High-Priority Watchdog Enable Tieoff set for the ESM Subsystem. Hence, Group 0 events are mapped to High-Priority Interrupt Outputs and the High-Priority Watchdog Counter is enabled by default.

7.3.8.1 Group0 High-Priority Tieoff

All group 0 events are pre-set to be both enabled and high priority. This is the equivalent of a write to both the Error Group 0 Interrupt Enabled Set Register and Error Group 0 Interrupt Priority Register.

This setting defaults all Group 0 events to drive the high-priority interrupt by default after POR or global soft reset. Group 0 events can still be configured. The user can lock and commit by writing bit 0 of the Group *N* Interrupt Lock Register and Group *N* Interrupt Commit Register.

Additionally, pre-setting the error events for Group 0 in this way results in Group 0 by passing global enable. This means that a high-priority interrupt can be triggered before software has written any configuration to the ESM.

7.3.8.2 High-Priority Watchdog Enable Tieoff

The high-priority watchdog enable is set that is equivalent to a write of 0xA to the High Priority Watchdog Config Register.

This defaults the High-Priority Watchdog to be enabled by default after POR or global soft reset although the user can still disable by software. Additionally, the user can lock and commit the watchdog settings by writing to the watchdog lock/commit (bit 0) of the MMR Config Lock Register and MMR Config Commit Register. Pre-setting the High-Priority Watchdog Enable in this way results in the High-Priority Watchdog Interrupt bypassing global enable. This means that a high-priority watchdog interrupt can be triggered before software has written any configuration to the ESM.

Note

As both High-Priority Watchdog Enable Tieoff and the Group0 High-Priority Enable Tieoff are enabled by default, care is taken that the high-priority watchdog counter preload default value (0x0000 FFFF) is sufficiently large such that a Group 0 event that occurs during boot does not trigger a High-Priority Watchdog Interrupt before a CPU can service the Group 0 event; as when the High-Priority Watchdog triggers a CPU reset, this can result in a reset loop if the High-Priority Watchdog triggers before a CPU is awake to handle a Group 0 event. The user can change the preload counter value as required later.

7.4 ESM Configuration Guide

The following steps are to be performed by user depending on the error handling and condition control:

1. Configure the error event to affect either low-priority or high-priority interrupt for respective ESM instance. Error events that cause CPU to go into fault state must be configured to high-priority interrupt to trigger NMI to respective CPU. For System ESM instance, high-priority interrupt priority is not applicable.
2. Enable Interrupt generation for respective error event using Interrupt Enable Set Register. Based on Step1, the enabled interrupt event when active triggers selected priority error event.
3. Configure Global Enable to enable all interrupts, this is interrupt mask for all error events.
4. If the error event needs to affect the critical-priority interrupt, set the respective event in the Critical Priority Interrupt Influence Set Register.
5. In Step 1 if the interrupt priority is set to trigger a high-priority interrupt, watchdog on high-priority interrupt is enabled at start-up with tie-off unless the user wants to disable.
6. Optionally Lock and Commit the configurations.
7. For System ESM only: If error needs to be enabled to influence error pin, enable the event using Error Pin Influence Set Register. Error Pin configurations are only applicable to System ESM instance.
8. For System ESM only: After Step 7, Enable the Error Pin Monitor using Error Pin Monitor Config Register and enable Error Pin Monitor Interrupt using the Error Pin Monitor Interrupt Status/Set Register.

The previous steps can also be visualized with [Figure 7-15](#) and [Figure 7-16](#). These views show how each individual error event represented by Error Event_j (where j is the global error event number from 0 to 255) as an input to the ESM instance can be configured to then output selected error response to the device. Note that for Group0 (error events 0-31), the Global Enable is bypassed due to the Group0 High-Priority Tieoff.

Figure 7-15. ESM CPU Register Configuration View

Figure 7-16. System ESM Register Configuration View

7.5 Interrupt Condition Control and Handling

This section describes in detail about each Interrupt type condition control and handling.

7.5.1 ESM Low-Priority Error Interrupt

Any error event can be mapped to the low-priority error interrupt. A low-priority error interrupt is generated when an event is enabled to cause an interrupt (using the Error Group *N* Interrupt Enable Set Register) and mapped to the low-priority error interrupt (using the Error Group *N* Interrupt Priority Register) and the raw status is set (using the Error Group *N* Event Raw Status/Set Register).

When a low-priority error interrupt is received, the acting processor is recommended to follow the outlined steps:

1. Read the Low-Priority Prioritized Register:
 - If both [31-16] PLS (low_pulse_prio) or [15-0] LVL (low_level_prio) bit fields are equal to 0xFFFF, then Interrupt is no longer asserted/pending.
 - If either [31-16] PLS (low_pulse_prio) or [15-0] LVL (low_level_prio) bit fields are not equal to 0xFFFF, software has two options for determining what event to service:
 - First Option: Record the value in low_pulse_prio and/or low_level_prio. Determine which is higher priority. This is the Global Event Number of the highest priority in Low Priority Error Event.
 - Second Option:
 - Read the Low Priority Interrupt Status Register to determine which Event Groups have pending low-priority interrupts.
 - Read the desired Error Group *N* Interrupt Enabled Status/Clear Register.
 - Identify which low-priority interrupt to service.
2. Based on the global event map for the device, find the error event source.
3. Service the error event based on the individual peripheral specification:
 - a. The system takes several actions including (but not limited to):
 - i. Fixing the error
 - ii. Resetting the errored peripheral
 - iii. Resetting the device
 - iv. Communicating outside the device using the error pin for outside intervention

Rest of the steps assume the error handling is complete and system wants to clear the error event. Clearing of error event is:

Pulse Events

When a low-priority error pulse event has to be cleared, the acting processor must perform the following steps in order:

1. Write 0x1 to the appropriate bit in the Error Group *N* Interrupt Enabled Status/Clear Register. This step clears the raw status and de-asserts the level interrupt.
2. Write the end of interrupt vector to the EOI Interrupt Register. In case there are enabled error events pending, then a new pulse is generated and level interrupt remains asserted; else, no new pulse is generated.
3. Clear the Error Event at the source. The source generates a new pulse that shows up as a new error event at the ESM.
4. Write a CLEAR (0x5) to the Error Pin Control Register. This step is optional if the event is not enabled to influence the error pin (using the Error Pin Influence Set Register), but recommended to be done regardless as an extra CLEAR is not harmful.

7.5.2 ESM High-Priority Error Interrupt

Any error event can be mapped to the high-priority error interrupt. A high-priority error interrupt is generated when an event is enabled to cause an interrupt (using the Error Group *N* Interrupt Enable Set Register) and mapped to the high-priority error interrupt (using the Error Group *N* Interrupt Priority Register) and the raw status is set (using the Error Group *N* Event Raw Status/Set Register).

When a high-priority error interrupt is received, the acting processor is recommended to follow the outlined steps:

1. Read the High Priority Prioritized Register:
 - If both [31-16] PLS (high_pulse_prio) or [15-0] LVL (high_level_prio) bit fields are equal to 0xFFFF, then Interrupt is no longer asserted/pending.
 - If either [31-16] PLS (high_pulse_prio) or [15-0] LVL (high_level_prio) bit fields are not equal to 0xFFFF, software has two options for determining what event to service:
 - First Option: Record the value in high_pulse_prio and/or high_level_prio. Determine which is higher priority. This is the Global Event Number of the highest priority in High-Priority Error Event.
 - Second Option:
 - Read the High-Priority Interrupt Status Register to determine which Event Groups have pending high-priority interrupts.
 - Read the desired Error Group *N* Interrupt Enabled Status/Clear Register.
 - Identify which high-priority interrupt to service.
2. Determine, based on the global event map for the device, find the error event source.
3. Service the error event based on the peripherals specification:
 - a. The system takes several actions including (but not limited to):
 - i. Fixing the error
 - ii. Resetting the errored peripheral
 - iii. Resetting the device
 - iv. Communicating outside the device using the error pin for outside intervention

Rest of the steps assume the error handling is complete and system wants to clear the error event. Clearing of error event is:

Pulse Events

When a high-priority error pulse event has to be cleared, the acting processor must perform the following steps in order:

1. Write 0x1 to the appropriate bit in the Error Group *N* Interrupt Enabled Status/Clear Register. This step clears the raw status and de-asserts the level interrupt.
2. Write the end of interrupt vector to the EOI Interrupt Register. In case there are enabled error events pending, then a new pulse is generated and level interrupt remains asserted; else, no new pulse is generated.
3. Clear the Error Event at the source. The source generates a new pulse that shows up as a new error event at the ESM.
4. Write a CLEAR (0x5) to the Error Pin Control Register. This step is optional if the event is not enabled to influence the error pin (using the Error Pin Influence Set Register), but recommended to be done regardless as an extra CLEAR is not harmful.

7.5.3 Critical-Priority Error Interrupt

Any error event can be mapped to the critical-priority interrupt. A high-priority error interrupt is generated when an event is enabled to cause an interrupt (using the Error Group *N* Critical Priority Interrupt Influence Set Register) and the raw status is set (using the Error Group *N* Event Raw Status/Set Register).

When a critical-priority error interrupt occurs, the following steps must be performed by acting processor:

1. Read the Info Register to confirm that the critical-priority error output triggered.
2. Read the Error Group *N* Critical Priority Interrupt Influence Set Register and the raw status in the Error Group *N* Event Raw Status/Set Register to determine the input error events that triggered the critical-priority error interrupt.
3. Perform Global Soft Reset to clear the Info Register (Base Address + 0x04) critical-priority error interrupt status bit as well as all raw interrupt status.
4. If the critical-priority error interrupt resulted in an ESM Warm Reset, re-enable the Global Enable Register.

7.5.4 High-Priority Watchdog Interrupt

The high-priority watchdog interrupt occurs when the process tasked with servicing the high-priority interrupt has failed to do so for an amount of time set by the pre-loaded timeout value. The device can use the high-priority watchdog interrupt as a reset request.

The following actions must be taken by acting processor for Interrupt handling:

- If the high-priority watchdog interrupt triggers an ESM Warm Reset, the Global Enable Register is reenabled after servicing all outstanding errors that triggered the high-priority watchdog interrupt and servicing the high-priority interrupt.
- Write EOI vector to the EOI Interrupt Register or the Interrupt Clear results in a re-evaluation of the high-priority watchdog interrupt.

7.5.5 Safety Aggregator Interrupt Control and Handling

The safety aggregator generates the non-correctable error interrupt where hardware cannot correct the error in case of parity checker error.

The following is the sequence for servicing interrupts:

- Software enables the interrupts for a each edc_ctrl interface by writing 0x1 to the corresponding bit of the Interrupt Enable Register (DED_ENABLE_SET_REG0).
- On receiving an interrupt, software checks which edc_ctrl interface has caused the error by reading the Interrupt Status Register (using DED_STATUS_SET_REG0).
- Software writes the edc_ctrl interface ID in the ECC vector field bits 10:0 along with the read message that includes setting bit 15 to trigger the serial VBUS read and writing the address to bits 23:16. The address corresponds to the register to read from the EDC controller component. Refer to the EDC Controller Register for more details.
- Software polls the read done bit (bit 24) in the ECC Vector Register.
- To clear the interrupt, software does a write operation to the Error Status 1 Register to clear injected error and writes 0x1 to the End of Interrupt Register to clear the interrupt (using DED_EOI_REG).

7.6.4 ESM Examples

NOTE: These examples are located in the F29x SDK installation from ti.com at the following location:
f29h85x-sdk_X_XX_XX_XX/examples/driverlib/CORE_IF_MULTICORE/esm

Cloud access to these examples is available at the following link: [dev.ti.com F29x SDK Examples](https://dev.ti.com/F29x_SDK_Examples).

7.6.4.1 ESM Multicore Example (CPU1,CPU3) - MULTI_CORE

FILE: esm_cpu1_cpu3_multi_c29x1.c

This example demonstrates how to handle fault conditions using ESM and Error Aggregator in a multi-core example (ESM_cpu1_cpu3_multi_c29x1.c).

When using CCS for debugging this Multi-core example, after launching the debug session,

- Connect to CPU1 and load only the c29x1.out.
- After the program is loaded, run CPU1.
- Once c29x1 configures and releases CPU3 out of reset, the program stops.
- Connect to CPU3 target now. c29x3.out would have started execution as soon as it is released from reset.
- In case of RAM configuration, restart the CPU3 target and load the symbols.

For FLASH configuration, this example is run in FLASH BANKMODE2, where CPU3 has access to FLASH (FRI-2). Refer to the Flash Plugin documentation to know about changing FLASH BANKMODEs and more. Additionally, the CPAX and CDAX RAMs are used for allocating various RAM sections. *External Connections*

- None.

7.6.4.3 ESM - SINGLE_CORE

FILE: esm_ex1_tmuromparity_test.c

Example shows how to generate and check the error response configuration during development phase of software. It highlights the capability to self test the error propagation path providing test for diagnostic (TMU ROM Parity logic) Note - TMU ROM parity error puts CPU in fault state and only NMI can take CPU out of the fault state.

External Connections

- None.

Watch Variables

- error_generated - check if the proper error is generated

7.6.4.4 ESM - SINGLE_CORE

FILE: esm_ex2_safetyaggregator.c

This example shows how to do parity error injection for safety aggregator and generate parity error interrupt using the safety aggregator. For parity error generation, the example injects a single bit error and waits for the code execution to jump to parity error ISR in for loop. The parity error ISR clears the DED_STATUS_REG and sets EOI to acknowledge future Parity interrupts.

External Connections

- None.

Watch Variables

- ISRCount - The number of times entered into the ESM Parity Error ISR
- loopCount - The number of loops performed while not in ISR

7.7 ESM Registers

This Section describes the ESM Registers.

7.7.1 ESM Base Address Table

Table 7-9. ESM Base Address Table

Structure	DriverLib Name	Base Address	Frame Applicable	CPU1	CPU2	CPU3	RTDMA1	RTDMA2	HSM	Pipeline Protected
ESM_CPU_REGS	ESMCPU1_BASE	0x6009_0000	YES	YES	YES	YES	YES	YES	-	YES
ESM_CPU_REGS	ESMCPU2_BASE	0x6009_1000	YES	YES	YES	YES	YES	YES	-	YES
ESM_CPU_REGS	ESMCPU3_BASE	0x6009_2000	YES	YES	YES	YES	YES	YES	-	YES
ESM_SYSTEM_REGS	ESMSYSTEM_BASE	0x6009_F000	YES	YES	YES	YES	YES	YES	-	YES
ESM_SAFETY_AGG_REGS	ESMSAFETYAGG_BASE	0x600A_0000	-	YES	YES	YES	YES	YES	-	YES

7.7.2 ESM_CPU_REGS Registers

Table 7-10 lists the memory-mapped registers for the ESM_CPU_REGS registers. All register offset addresses not listed in Table 7-10 should be considered as reserved locations and the register contents should not be modified.

Table 7-10. ESM_CPU_REGS Registers

Offset	Acronym	Register Name
0h	PID	Revision Register
4h	INFO	Info Register
8h	EN	Global Enable Register
Ch	SFT_RST	Global Soft Reset Register
20h	LOW_PRI	Low Priority Prioritized Register
24h	HI_PRI	High Priority Prioritized Register
28h	LOW	Low Priority Interrupt Status Register
2Ch	HI	High Priority Interrupt Status Register
30h	EOI	EOI Interrupt Register
80h	HI_PRI_WD_CFG	High Priority Watchdog Config Register
84h	HI_PRI_WD_CNTR	High Priority Watchdog Counter Value Register
88h	HI_PRI_WD_CNTR_PRE	High Priority Watchdog Pre-Load Register
8Ch	HI_PRI_WD_INTR_SET	High Priority Watchdog Interrupt Status/Set Register
90h	HI_PRI_WD_INTR_CLR	High Priority Watchdog Interrupt Status/Clear Register
100h	GROUP_N_LOCK	Group N Interrupt Lock Register
104h	GROUP_N_COMMIT	Group N Interrupt Commit Register
118h	CRI_PRI_INFLUENCE_LOCK	Critical Priority Interrupt Influence Lock Register
11Ch	CRI_PRI_INFLUENCE_COMMIT	Critical Priority Interrupt Influence Lock Register
120h	MMR_CONFIG_LOCK	MMR Config Lock Register
124h	MMR_CONFIG_COMMIT	MMR Config Commit Register
400h + formula	RAW_j	Error Group N Event Raw Status/Set Register
404h + formula	STS_j	Error Group N Interrupt Enable Status/Clear Register
408h + formula	INTR_EN_SET_j	Error Group N Interrupt Enable Set Register
40Ch + formula	INTR_EN_CLR_j	Error Group N Interrupt Enabled Clear Register
410h + formula	INT_PRIO_j	Error Group N Interrupt Priority Register
800h + formula	CRIT_EN_SET_j	Error Group N Critical Priority Interrupt Influence Set Register
804h + formula	CRIT_EN_CLR_j	Error Group N Critical Priority Interrupt Influence Clear Register

Complex bit access types are encoded to fit into small table cells. Table 7-11 shows the codes that are used for access types in this section.

Table 7-11. ESM_CPU_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		

Table 7-11. ESM_CPU_REGS Access Type Codes (continued)

Access Type	Code	Description
<i>-n</i>		Value after reset or the default value
Register Array Variables		
<i>i,j,k,l,m,n</i>		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
<i>y</i>		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

7.7.2.1 PID Register (Offset = 0h) [Reset = 6FE03101h]

PID is shown in [Figure 7-17](#) and described in [Table 7-12](#).

Return to the [Summary Table](#).

The Revision Register contains the major and minor revisions for the module.

Figure 7-17. PID Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 7-12. PID Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	scheme	R	1h	PID register scheme
29-28	bu	R	2h	Business Unit: 10 = Processors
27-16	func	R	FE0h	Module ID
15-11	rtl	R	6h	RTL revision. Will vary depending on release.
10-8	major	R	1h	Major revision
7-6	custom	R	0h	Custom
5-0	minor	R	1h	Minor revision

7.7.2.2 INFO Register (Offset = 4h) [Reset = XXXX0808h]

INFO is shown in [Figure 7-18](#) and described in [Table 7-13](#).

Return to the [Summary Table](#).

The Info Register gives the configuration Information of this ESM.

Figure 7-18. INFO Register

31	30	29	28	27	26	25	24
last_reset	crit_intr	RESERVED

7.7.2.5 LOW_PRI Register (Offset = 20h) [Reset = FFFFFFFFh]

LOW_PRI is shown in [Figure 7-21](#) and described in [Table 7-16](#).

Return to the [Summary Table](#).

Shows which is the highest priority outstanding low priority interrupt

Figure 7-21. LOW_PRI Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
pls																lvl															
R-FFFFFFh																R-FFFFFFh															

Table 7-16. LOW_PRI Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	pls	R	FFFFh	This is the highest priority outstanding low priority pulse interrupt The lowest event number has the highest priority. A value of all ones (0xFFFF) indicates that there are no low priority interrupts pending. This field is updated whenever a new, higher priority event occurs
15-0	lvl	R	FFFFh	This is the highest priority outstanding low priority level interrupt The lowest event number has the highest priority. A value of all ones (0xFFFF) indicates that there are no low priority interrupts pending. This field is updated whenever a new, higher priority event occurs

7.7.2.6 HI_PRI Register (Offset = 24h) [Reset = FFFFFFFFh]

HI_PRI is shown in [Figure 7-22](#) and described in [Table 7-17](#).

Return to the [Summary Table](#).

Shows which is the highest priority outstanding high priority interrupt

Figure 7-22. HI_PRI Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

7.7.2.10 HI_PRI_WD_CFG Register (Offset = 80h) [Reset = 000000XAh]

HI_PRI_WD_CFG is shown in [Figure 7-26](#) and described in [Table 7-21](#).

Return to the [Summary Table](#).

The High Priority Watchdog Config Register is used to enable or disable the High Priority Watchdog and its associated interrupt.

Figure 7-26. HI_PRI_WD_CFG Register

Bit	Field	Type	Reset	Description
31-12	RESERVED	R/W	0h	
11-8	emu_free	R/W	0h	Enable free running mode for the High Priority Watchdog to bypass the debug suspend input. 0xA Enable the watchdog counter during debug suspend. For all other values the counter will freeze during emulation when the debug suspend input is high.
7-4	RESERVED	R/W	Xh	
3-0	wd_en	R/W	Ah	Enable field for the High Priority Watchdog. 0xA Enables the watchdog. All other values disable the watchdog

7.7.2.11 HI_PRI_WD_CNTR Register (Offset = 84h) [Reset = 0000FFFFh]

HI_PRI_WD_CNTR is shown in [Figure 7-27](#) and described in [Table 7-22](#).

Return to the [Summary Table](#).

The High Priority Watchdog Counter Register reflects the current value of the High Priority Watchdog Counter. When enabled, this counter will start decrementing (from the High Priority Pre-Load value) as soon as any of the enabled Errors associated with the High Priority Interrupt is active. This counter is reset by the warm reset.

Figure 7-27. HI_PRI_WD_CNTR Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

7.7.2.13 HI_PRI_WD_INTR_SET Register (Offset = 8Ch) [Reset = 00000000h]

HI_PRI_WD_INTR_SET is shown in [Figure 7-29](#) and described in [Table 7-24](#).

Return to the [Summary Table](#).

The High Priority Watchdog Status/Set Register indicates the status of the High Priority Watchdog Interrupt. This register is reset by the Power On Reset. A write to this register may allow software to set the interrupt output.

Figure 7-29. HI_PRI_WD_INTR_SET Register

0	val	R/W1S	0h	Read the current interrupt status. Write 1 to set the interrupt output

7.7.2.14 HI_PRI_WD_INTR_CLR Register (Offset = 90h) [Reset = 00000000h]

HI_PRI_WD_INTR_CLR is shown in [Figure 7-30](#) and described in [Table 7-25](#).

Return to the [Summary Table](#).

The High Priority Watchdog Status/Clear Register indicates the status of the High Priority Watchdog Interrupt. This register is reset by the Power On Reset. A write to this register may allow software to temporarily clear the interrupt.

Figure 7-30. HI_PRI_WD_INTR_CLR Register

31-1	RESERVED	R/W	0h	
0	val	R/W1C	0h	Read the current interrupt status. Write 1 to clear the interrupt output. The interrupt will reassert if the conditions that triggered it persist

7.7.2.15 GROUP_N_LOCK Register (Offset = 100h) [Reset = 00000000h]

GROUP_N_LOCK is shown in [Figure 7-31](#) and described in [Table 7-26](#).

Return to the [Summary Table](#).

The fields of the Group N Interrupt Lock Register lock the configuration for the associated Error Group N Interrupt Enable Set/Clear Registers and the Error Group N Interrupt Priority Register. This locks the associated enable and priority bits for each Group for Low and High Priority Interrupts. Locks may be written until the associated Commit MMR fields are set to 1. Once Lock is 1 and Commit is 1, the associated configuration may not be changed until reset.

Figure 7-31. GROUP_N_LOCK Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 7-26. GROUP_N_LOCK Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	lock	R/W	0h	Each bit lock[N] bit will lock the associated masking MMRs associated with Group N. These are: Error Group N Interrupt Enabled Set Register, Error Group N Interrupt Enabled Clear Register, Error Group N Interrupt Priority Register

7.7.2.16 GROUP_N_COMMIT Register (Offset = 104h) [Reset = 00000000h]

GROUP_N_COMMIT is shown in [Figure 7-32](#) and described in [Table 7-27](#).

Return to the [Summary Table](#).

The fields of the Group N Interrupt Commit Register commit the lock configuration for the associated Group N Interrupt Lock Register. This prevents the Locks in the Group N Interrupt Lock Register from changing. Once Commit is 1, the associated Lock and Commit may not be changed until reset.

Figure 7-32. GROUP_N_COMMIT Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit	Field	Type	Reset	Description
31-0	commit	R/W	0h	Each bit commit[N] bit will commit the lock configuration for the corresponding bit in the Group N Interrupt Lock Register.

7.7.2.17 CRI_PRI_INFLUENCE_LOCK Register (Offset = 118h) [Reset = 00000000h]

CRI_PRI_INFLUENCE_LOCK is shown in [Figure 7-33](#) and described in [Table 7-28](#).

Return to the [Summary Table](#).

The fields of the Critical Priority Interrupt Influence Lock Register lock the Critical Priority Interrupt Influence configuration for the associated Error Groups. Locks may be written until the associated Commit MMR fields are set to 1. Once Lock is 1 and Commit is 1, the associated configuration may not be changed until reset.

Figure 7-33. CRI_PRI_INFLUENCE_LOCK Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

7.7.2.18 CRI_PRI_INFLUENCE_COMMIT Register (Offset = 11Ch) [Reset = 00000000h]

CRI_PRI_INFLUENCE_COMMIT is shown in [Figure 7-34](#) and described in [Table 7-29](#).

Return to the [Summary Table](#).

The fields of the Critical Priority Interrupt Influence Commit Register commit the lock configuration for the associated Error Groups. This prevents the Locks in the Critical Priority Interrupt Influence Lock Register from changing. Once Commit is 1, the associated Lock and Commit may not be changed until reset.

Figure 7-34. CRI_PRI_INFLUENCE_COMMIT Register

7.7.2.19 MMR_CONFIG_LOCK Register (Offset = 120h) [Reset = 000000XXh]

MMR_CONFIG_LOCK is shown in [Figure 7-35](#) and described in [Table 7-30](#).

Return to the [Summary Table](#).

The fields of the MMR Config Lock Register lock the configuration for the associated MMRs. This prevents changes once the lock configuration is committed with the MMR Config Commit Register. Locks may be written until the associated Commit MMR fields are set to 1. Once Lock is 1 and Commit is 1, the associated configuration may not be changed until reset.

0	hi_pri_wd_lock	R/W	0h	Locks the High Priority Watchdog configuration registers. These are: High Priority Watchdog Config Register, High Priority Watchdog Pre-Load Register.

7.7.2.20 MMR_CONFIG_COMMIT Register (Offset = 124h) [Reset = 000000XXh]

MMR_CONFIG_COMMIT is shown in [Figure 7-36](#) and described in [Table 7-31](#).

Return to the [Summary Table](#).

The fields of the MMR Config Commit Register commit the lock configuration for the associated MMR Config Lock MMR bits. This prevents the Locks in the MMR Config Lock Register from changing. Once Commit is 1, the associated Lock and Commit may not be changed until reset.

Figure 7-36. MMR_CONFIG_COMMIT Register

Complex bit access types are encoded to fit into small table cells. Table 7-40 shows the codes that are used for access types in this section.

Table 7-40. ESM_SYSTEM_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

7.7.3.1 PID Register (Offset = 0h) [Reset = 6FE03101h]

PID is shown in [Figure 7-44](#) and described in [Table 7-41](#).

Return to the [Summary Table](#).

The Revision Register contains the major and minor revisions for the module.

Table 7-72. PIN_EN_SET_j Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	msk	R/W1S	0h	This is the error pin influence enable set for errors in Group N. Each bit corresponds to event Q where $Q = N * 32 + \text{Bit}$, e.g. bit 0 is event $N * 32 + 0$, bit 1 is $N * 32 + 1$, etc. If the corresponding bit and the global_enable are set, then the interrupt is unmasked. This field is only reset by a Power-On-Reset, not warm reset. A global soft reset will set this field to 0. Read 0 is Disabled. Read 1 is Enabled. Write 0 has no effect. Write 1 sets the Enable. The corresponding event, when set, will count as a pending error event for the ESM state machine.

7.7.3.33 PIN_EN_CLR_j Register (Offset = 418h + formula) [Reset = 00000000h]

PIN_EN_CLR_j is shown in [Figure 7-76](#) and described in [Table 7-73](#).

Return to the [Summary Table](#).

Error Pin Enabled Clear register

7.7.4 ESM_SAFETYAGG_REGS Registers

Table 7-76 lists the memory-mapped registers for the ESM_SAFETYAGG_REGS registers. All register offset addresses not listed in Table 7-76 should be considered as reserved locations and the register contents should not be modified.

Table 7-76. ESM_SAFETYAGG_REGS Registers

Offset	Acronym	Register Name
0h	rev	Aggregator Revision Register
8h	vector	ECC Vector Register
Ch	stat	Misc Status
10h + formula	reserved_svbus_y	Reserved Area for Serial VBUS Registers
13Ch	ded_eoi_reg	EOI Register
140h	ded_status_reg0	Interrupt Status Register 0
180h	ded_enable_set_reg0	Interrupt Enable Set Register 0
1C0h	ded_enable_clr_reg0	Interrupt Enable Clear Register 0
200h	aggr_enable_set	AGGR interrupt enable set Register
204h	aggr_enable_clr	AGGR interrupt enable clear Register
208h	aggr_status_set	AGGR interrupt status set Register
20Ch	aggr_status_clr	AGGR interrupt status clear Register

Complex bit access types are encoded to fit into small table cells. Table 7-77 shows the codes that are used for access types in this section.

Table 7-77. ESM_SAFETYAGG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Wdecr	W decr	Write
Wincr	W incr	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

7.7.4.1 rev Register (Offset = 0h) [Reset = 66A03A01h]

8.1 Introduction to Flash Memory

Flash is a type of electrically erasable and programmable non-volatile memory. In C2000™ real-time microcontrollers, Flash memory is primarily used to store application code, which executes directly from the internally embedded Flash memory banks. Additionally, Flash can be used to store static data that needs to be preserved between power cycles or device resets.

This chapter describes the structure of Flash memory modules in the device, the proper sequence to initialize and configure Flash, how to improve Flash performance by enabling prefetch and cache mechanisms, and mechanisms for management of firmware updates.

8.1.2 Features

The features of Flash memory include:

- Up to 8 Flash program code banks, 4 of which can optionally be allocated to CPU3 (if available) at boot time for instruction fetches (For the number and size of Flash banks, refer to the device data manual);
- Up to two Flash controller modules, with up to four program banks per module;
- One dedicated data Flash bank housed in Flash Controller 1 (FLC1), optimized for data bus read accesses;
- Enhanced Flash Read Interface module (FRI), with interleaving of program bank pairs for high performance during 128 bit-wide instruction word fetches;
- Each Flash Controller can program or erase a Flash bank or bank pair while simultaneously reading from the other pair of Flash banks;
- Tight integration with the Safety and Security Unit (SSU) for security management and access control for Flash program, erase and read operations;
- 128-bit-wide Flash programming, with configurable programming options;
- Multiple sectors, with the ability to erase individual/specific sectors while leaving others programmed;
- Dedicated SECCFG Flash regions for storing user security policy settings and boot mode options that are loaded at device start-up;
- BANKMGMT sectors for management of Flash firmware updates using FOTA or Live Firmware Update mechanisms, with anti-rollback protection capability;
- Code prefetch, block cache and data cache mechanisms for enhanced read performance for program code and data;
- Configurable wait states to achieve the best performance at a given clock frequency;
- Safety Features:
 - ECC error detection in address bits, with reporting to the Error Signaling Module (ESM);
 - Supports ECC bits for single error correction and double error detection (SECCDED);

- Integrated Flash program and erase state machines in the Flash Controller modules:
 - Simple Flash API algorithms;
 - Fast erase and program times (refer to the device data manual for details);
- Automatic arbitration of data accesses between multiple initiators (C29x CPUs, HSM, RTDMA and debugger accesses).

8.1.3 Flash Tools

Texas Instruments provides the following tools for Flash:

- Code Composer Studio™ (CCS) IDE - development environment with integrated Flash plugin. TI recommends performing a debug reset and restart before programming the code into Flash using CCS.
- Flash API Library - set of software peripheral functions to erase/program Flash.
- UniFlash - standalone tool to erase/program/verify the Flash content through JTAG. No CCS usage is required.

Note

Users must check and install available updates for the CCS On-Chip Flash Plugin and UniFlash tools.

8.1.4 Block Diagram

A top-level block diagram of the Flash subsystem is shown in Figure 8-1.

Figure 8-1. Flash Subsystem Block Diagram

8.2 Flash Subsystem Overview

At the core of the Flash subsystem are one or more Flash Controllers (FLCn), which interface directly with the Flash banks and charge pump. Each Flash controller performs the following primary functions:

- Provides a simple interface for software to program or erase the Flash memory.
- Interfaces with the Flash Bank Access Router (FBAR) for reads of program code and data.
- Provides the capability to block unwanted bank program or erase operations.

Additionally, there are four Flash Read Interfaces (FRI-n), which provide an interface for various initiators in the device to read from Flash memory. The Flash Read Interfaces provide memory address regions for Flash read, and include buffer and cache mechanisms to maximize read performance. The Flash Bank Access Router (FBAR) connects each Flash read port to the associated Flash bank or bank pair, depending on MODE and SWAP configuration. These modules are explained in detail in the following sections. Accesses from all initiators to the Flash Read Interface or Flash Controller registers are filtered through the SSU access permission logic and HSM usurp controls.

8.3 Flash Banks and Pumps

This device includes up to 8 Flash application code banks, and one application data bank. Each Flash bank stores code or data as 128-bit Flash words, plus 16 bits of ECC per Flash word. To meet the performance requirements of the C29x CPU, each group of two code banks is interleaved to form a bank pair, enabling 256-bit instruction fetches. The data bank is a single bank, and does not require interleaving since the C29x data buses are 64-bits wide. The Flash API automatically handles the addressing and interleaving of code banks, enabling user code to perform program and erase operations on interleaved bank pairs with a single command.

For naming purposes, each bank or bank pair is referred to by the Flash controller name and bank numbers. Banks are numbered starting with 0. For example, FLC2.B0/B1 refers to the first interleaved bank pair in Flash Controller 2, and FLC1.B4 refers to the 5th non-interleaved bank in FLC1, which is a data bank.

Each bank is divided into the following regions:

1. **MAIN:** This region is the primary storage region for the Flash bank, and is used to store application code and data.
2. **SECCFG:** This region contains security policy settings (also known as the User Protection Policy (UPP)), and other device configuration parameters. Security policy settings are loaded by the boot ROM into the Safety and Security Unit (SSU). For more information and content mapping for the SECCFG region, see [Section 9.8.2](#).
3. **BANKMGMT:** This region is used to manage firmware updates using Firmware-Over-The-Air (FOTA) or Live Firmware Update (LFU) processes. The BANKMGMT sector also contains code version information for rollback protection. For more information on the BANKMGMT region, see [Section 9.8](#).

Each Flash controller also contains a charge pump. The charge pump generates the special voltages and currents required for Flash program, erase and read operations.

8.4 Flash Read Interfaces

The Flash subsystem includes up to four Flash Read Interface modules (FRI-n). The Flash read interface modules provide a means for the various initiators on the system to perform read operations on Flash memory. These initiators include:

- **C29x CPUs:** Each CPU has one 128-bit instruction fetch bus, and two 64-bit data buses. In the C29x architecture, only primary CPUs (odd-numbered) have access to Flash memory for code fetch and data. Secondary CPUs (even-numbered) do not have access to Flash. Code that runs on an independent secondary CPU must first be copied to RAM and then executed from there.
- **RTDMA1:** The primary Real-Time DMA module can perform 64-bit data reads of Flash memory.
- **HSM:** If present, the Hardware Security Module can perform 32-bit data reads of Flash memory through the HSM_TO_SOC bus.
- **Debug Interface:** A debugger connected to either the C29x CPU or HSM CPU can perform data read accesses to Flash memory locations.

Each Flash read interface is addressable through one or more Flash read ports. Because of bank interleaving, multiple CPU support, and support for bank swapping during firmware updates, Flash code banks do not have a fixed mapping to CPU address space. Rather, each read port has a fixed address range, but can map to a different Flash region depending on the current system configuration. The Flash bank access router performs the background translation, routing read access requests to the intended bank or banks as directed by the Safety and Security Unit (SSU). There are two types of Flash read operations that can be performed: program instruction fetches for CPU execution, and data accesses.

Each of the Flash read interfaces is described in the following sections.

FRI-1: CPU1 Program

FRI-1 interfaces with the instruction fetch bus of the first C29x CPU (CPU1), and is primarily used for executing program code on CPU1. Additionally, FRI-1 is connected to all data read initiators in the system. This read interface has four read ports, numbered RP0 to RP3. These read ports are mapped to code banks depending on the configuration of BANKMODE and BANKMAP.CPU1SWAP registers in the SSU. These settings are described in subsequent sections.

FRI-2: CPU3 Program

On 3- or 4-CPU systems, FRI-2 interfaces with the instruction fetch bus of the third C29x CPU (CPU3). When program Flash memory is allocated to CPU3 by configuring BANKMODE, FRI-2 can be used to execute program code on CPU3, and additionally can be used as a data read interface by all initiators in the system. This read interface has two read ports, numbered RP0 to RP1. These read ports are mapped to code banks depending on the configuration of BANKMODE and BANKMAP.CPU3SWAP. On single-CPU systems, FRI-2 is not present.

FRI-3: Firmware Update Region

FRI-3 provides an address range to be used for programming and verifying an updated firmware image into the second half of Flash memory, while the current application continues to execute from the first half through FRI-1 and FRI-2 (if present). When the firmware update is complete, the Flash memory ranges can then be swapped using BANKMAP.CPUxSWAP, and the newly programmed firmware now executes from FRI-1 and FRI-2 (if present). This supports Firmware-Over-The-Air (FOTA) and Live Firmware Update (LFU) firmware upgrade mechanisms. FRI-3 does not have an instruction fetch interface—only data reads are possible from all system initiators. FRI-3 has two read ports, numbered RP0 to RP1, which are mapped to available Flash code memory.

FRI-4: Data Bank

FRI-4 is exclusively used for the data bank (FLC1.B4), and does not have an instruction fetch interface. Thus, application code cannot be executed from the data bank; only read accesses are possible from all system initiators. FRI-4 has one read port (RP0) which has a fixed mapping to the data Flash bank, and does not change based on the BANKMODE or BANKMAP.CPUxSWAP settings.

8.4.1 Bank Modes and Swapping

The BANKMODE register in the SSU_GEN_REGS register range configures the system Flash bank mode setting. These modes determine the allocation of Flash memory to primary C29x CPUs in the system, and whether the swapping feature is enabled for firmware updates. The BANKMODE register is loaded from the BANKMGMT sector of the active code bank pair in FLC1 during device boot. The active BANKMGMT sector is determined based on the values of the BANK_STATUS and BANK_UPDATE fields; afterward, the winning BANKMGMT sector is used to configure the system BANKMODE.

The available bank mode options are described in [Table 8-1](#).

Table 8-1. C29x CPU Bank Modes

BANKMODE	Flash Mapping	Swap Enabled	1-CPU Devices
0	All program Flash mapped to CPU1	No	Available
1		Yes	Available
2	Program Flash memory is split between CPU1 and CPU3	No	N/A
3		Yes	N/A

The BANKMAP register in SSU_GEN_REGS is used to determine the current active A/B swap setting for firmware updates using FOTA or LFU. This register contains a swap enable bit for each primary CPU (CPUxSWAP).

For specific mappings of Flash address ranges to read port addresses based on BANKMODE and CPUxSWAP settings, refer to the device data sheet.

8.4.2 Flash Wait States

When a CPU performs a read access to a Flash memory address, data is returned after (RWAIT + 1) SYSCLK cycles.

For an access to the SECCFG or BANKMGMT Flash regions, data is returned after 10 SYSCLK cycles.

RWAIT defines the number of random access wait states, and is configured using the RWAIT field in the FRDCNTL register. At reset, RWAIT defaults to a value of 2. RWAIT can be reconfigured to a lower value when the CPU clock frequency is low enough to accommodate the Flash access time. For a table of supported RWAIT values versus CPU clock frequency ranges, refer to the device data sheet.

For a given system clock frequency, configure RWAIT using the following formula:

$$RWAIT = \text{ceiling}\left(\frac{SYSCLK}{FCLK} - 1\right)$$

where SYSCLK is the system operating frequency, and where FCLK is the Flash clock frequency.

FCLK must be $\leq FCLK_{max}$, the allowed maximum Flash clock frequency.

If RWAIT results in a fractional value when calculated using the above formula, round up RWAIT to the nearest integer.

Note

The minimum value that RWAIT can be configured to on this device is 1. Zero wait state reads are not supported.

Note

If code flash is enabled, then the minimum value that RWAIT can be configured to is 2.

8.4.3 Buffer and Cache Mechanisms

Each Flash read interface includes mechanisms designed to maximize performance for read operations. These mechanisms include:

- An instruction prefetch buffer,
- A program code block cache, and
- A line buffer for data read operations.

These mechanisms are disabled by default at device boot, and must be configured to enable them before application execution commences.

8.4.3.1 Prefetch Mechanism and Block Cache

Flash memory is typically used to store application code. During code execution, instructions are fetched from contiguous memory addresses, except when a discontinuity occurs. Usually, the portion of code that resides in contiguous address locations makes up the majority of the application code, and is referred to as linear code. To improve the performance of linear code execution, the Flash read interface includes a code prefetch mechanism and block cache. The prefetch mechanism and block cache are available on FRI-1 (and FRI-2, if present). [Figure 8-2](#) shows a functional block diagram of the Flash prefetch mechanism and block cache.

The prefetch mechanism does a look-ahead prefetch on linear address increments, starting from the address of the last instruction fetch. The Flash prefetch mechanism is disabled by default. To enable prefetch mode, set the PREFETCH_EN bit in the FRIx_INTF_CTRL register to 1, or enable the FLASH_PREFETCH_ENABLE macro and call the Flash_configFRI() driverlib function.

Each instruction fetch from Flash memory reads out 256 bits total—128 bits from each half of an interleaved pair (not counting ECC bits). The starting address of the access from Flash is automatically aligned to a 256-bit boundary, such that the instruction location is within the 256 bits to be fetched. When the prefetch mechanism is enabled, the 256 bits read from the instruction fetch are stored in a 128-bit wide by 4-level deep instruction prefetch buffer. The contents of this prefetch buffer are then sent to the CPU for processing as required.

The C29x CPU receives instruction packets up to 128-bits wide, over a 128-bit program read bus. Each instruction packet can contain a combination of 16-bit, 32-bit, or 48-bit instructions. While the instructions are processing through the CPU, the Flash prefetch mechanism automatically initiates another access to the Flash bank to prefetch the next 256 bits. In this manner, the Flash prefetch mechanism works in the background to keep the instruction prefetch buffer as full as possible. Using this technique, the overall efficiency of sequential code execution from Flash is significantly improved.

In addition to the prefetch buffer, the Flash read interface includes a block cache mechanism, consisting of two 256 bit-wide by 32-deep blocks. The block cache sits between the prefetch buffer and the Flash banks, and is loaded with 256-bit data simultaneously with the prefetch buffer. Whenever there is a discontinuity in execution (such as a branch instruction), the mechanism checks if the requested data is already in the block cache. If so, the instruction data is read from the block cache and fed into the prefetch buffer, which then sends the data to the CPU on the next cycle. This improves the latency for discontinuity instructions to just one wait state, boosting code performance in short-branch loops and other minor discontinuities. To enable the block cache, set the CODE_CACHE_EN bit in the FRIx_INTF_CTRL register to 1, or enable the FLASH_CODECACHE_ENABLE macro and call the Flash_configFRI() driverlib function.

Note

The block cache is designed such that execution loops of 512 bytes or less run with minimum latency once loaded into the cache. Loops that are larger than 512 bytes exceed the size of one cache block, and in these cases, the performance benefit can be reduced.

Because the block cache interfaces between the prefetch buffer and the Flash banks, the prefetch mechanism must be enabled for the block cache to function. If the block cache is enabled without the prefetch buffer, neither mechanism ever gets loaded, and Flash performance is equivalent to both mechanisms being turned off. Always enable the prefetch buffer when enabling the block cache.

Figure 8-2. Flash Prefetch Mechanism and Block Cache

8.4.3.2 Data Line Buffer

To improve the performance of data reads, the Flash read interface includes a data line buffer. The size of the data line buffer is 288 bits for an interleaved bank pair (including 32 ECC bits), and 144 bits for a non-interleaved data bank (including 16 ECC bits). To activate the Flash data line buffer, write 1 to the DATA_CACHE_EN bit of the FRIx_INTF_CTRL register for the target Flash read interface.

When a read request is received from one or more initiators in the system, the upper portion of the address is compared to the buffer tag to determine if the requested data is in the line buffer. If a match is found, and the

valid bit (V) is set, then the Flash read interface returns data directly from the line buffer to the initiator, without making a new access to the Flash bank. The address of the data is also returned to the CPU for ECC checking.

There is a dedicated compare unit for each read initiator (for example, CPU1, RTDMA, debugger), so multiple initiators can read from the data line buffer simultaneously without added wait states. Figure 8-3 shows a functional block diagram of the data line buffer for interleaved bank pairs. Figure 8-4 shows a functional block diagram of the data line buffer for non-interleaved banks.

Figure 8-3. Flash Data Line Buffer for Interleaved Banks

Figure 8-4. Flash Data Line Buffer for Single Bank

If a query does not match the line buffer tag, then a read operation is performed on the associated Flash bank or bank pair. When the data is returned from the Flash, the Flash read interface sends the requested data portion to the CPU, updates the data line buffer, and sets the valid bit. For non-interleaved banks, the line buffer is always 128-bit aligned. For interleaved bank pairs, the line buffer contents are always 256-bit aligned, such that the lower 128 bits come from the first bank and the upper 128 bits come from the second bank. Figure 8-5 illustrates the mapping of interleaved bank pairs to data line buffer bits.

Figure 8-5. Interleaved Bank to Buffer Mapping

Note

Since each Flash Read Interface contains only one buffer, attempts to concurrently read data at different Flash addresses by multiple initiators through the same FRI can potentially lead to a bottleneck. In this situation, the line buffer contents are replaced by each concurrent request without being used. To prevent a slowdown in performance, avoid or limit simultaneous reads by multiple CPUs to the same Flash Read Interface.

The data line buffer valid bit is only cleared automatically on a reset. Always flush the buffer manually after programming or erasing Flash memory, or whenever a CPU fault is detected. To clear the valid bit and flush the buffer, write 1 to the DATA_CACHE_CLR bit of the corresponding FR1x_INTF_CLR register.

The Flash read interface registers can only be written to by CPU1. When programming or erasing Flash memory from another CPU (for example, CPU3), the application must request CPU1 to flush the data line buffer using IPC.

8.4.3.3 Sequential Data Pre-read Mode

Each Flash read interface provides a user-configurable sequential data pre-read mode. In this mode, the data line automatically pre-reads the Flash and refills the line buffer with the next sequential set of addresses after a previous read is completed. When sequential pre-read mode is active and an initiator reads the last 64-bit word in the line buffer (bits [255:192] for interleaved banks, [127:64] for single banks), the pre-read logic reads the next sequential Flash bank address, and replaces the buffer contents with the data read. The line buffer is then ready for the initiator at the next Flash read request. If an initiator requests a part of the data while the Flash read access is in progress, then the data is returned to the initiator as soon as the Flash read operation is complete.

Flash sequential data pre-read mode is turned off by default, and must be explicitly activated by the user. This mode is intended to be used only during sequential data reads for maximum performance. To enable sequential data pre-read mode, write 1 to the DATA_PREREAD_EN bit of the FR1x_INTF_CTRL for the target

read interface. When the sequential read operation is complete, write 0 to the DATA_PREREAD_EN bit to turn off the pre-read mechanism.

Note

The sequential data pre-read logic is part of the data line buffer, and cannot function if the line buffer is turned off. Always enable the line buffer when using sequential pre-read mode.

8.4.4 Flash Read Arbitration

Each Flash read interface contains multiple levels of arbitration to determine in which order concurrent read requests from multiple initiators are serviced.

1. The first level of arbitration is a fixed priority arbiter between C29x CPU buses. Data Read Bus 1 (DRB1) always gets a higher priority than Data Read Bus 2 (DRB2). This arbitration level enables zero-wait-state switching between the two data buses belonging to the same CPU. The actual data read bus used for a specific read request is automatically generated by the compiler.
2. The second level of arbitration is the L1 data read pipeline. This level arbitrates between data read requests generated by multiple initiators in the system. The initiators are selected using a round-robin pointer. The round-robin selection order for FRI-1, FRI-3, and FRI-4 is as follows:
 - a. CPU1
 - b. CPU2 (if present)
 - c. CPU3 (if present)
 - d. CPU4 (if present)
 - e. RTDMA
 - f. HSM (if present)
 - g. Data Pre-read
 - h. Debugger

The round-robin selection order for FRI-2, if present, is as follows:

- a. CPU3
- b. CPU4 (if present)
- c. CPU1
- d. CPU2 (if present)
- e. RTDMA
- f. HSM (if present)
- g. Data Pre-read
- h. Debugger

Switching between initiators incurs a one-cycle pipeline delay, to allow for the round-robin pointer change.

3. For FRI-1 (and FRI-2, when present), there is a third level of arbitration between fetch and data requests (L2). This arbiter is also a round-robin arbiter like the second level, selecting using the following order:
 - a. Instruction fetch (CPU1 for FRI-1, CPU3 for FRI-2)
 - b. L1 data read pipeline output

Changes to the L2 round-robin pointer incur a one-cycle pipeline delay, similar to the L1 arbiter.

8.4.5 Error Correction Code (ECC) Protection

The F29x platform devices feature an end-to-end safety architecture, with ECC logic built into the C29x CPU. When a Flash data read or instruction fetch operation is performed, ECC check bits are sent along with the data bits onto the CPU program or data buses. The CPU automatically checks incoming instructions and data using the ECC bits, correcting single-bit data errors, and generating a fault for double-bit (uncorrectable) errors. These errors generate events to the Error Signaling Module (ESM), which in turn can generate a regular interrupt for a single-bit error, or a non-masking interrupt (NMI) for a double-bit error.

Each 8-bit ECC code is computed based on the requested data address and 64 bits of data. For each 128-bit Flash word, there are two ECC codes (upper 64 bits and lower 64 bits), for a total of 16 ECC bits. ECC bits can be independently read through separate FRI read port memory regions as described in the device data sheet.

For more information on ECC protections, see [Chapter 2](#).

Note

Because the ECC logic is built into the C29x CPU, read accesses from other initiators such as the debugger, RTDMA or HSM CPU do not have ECC protection. Flash reads from these initiators do not have error detection and correction enabled.

8.4.6 Procedure to Change Flash Read Interface Registers

While configuring a Flash Read Interface (FRI), no accesses to any Flash memory that is covered by the Flash Read Interface can be in progress. This includes instructions still in the CPU pipeline, data reads, and instruction prefetch operations. To be sure that no access takes place during the configuration change, follow the procedure shown below for any code that modifies the Flash Read Interface registers.

Note

Flash Read Interface registers can only be modified by code running as CPU1.LINK2, CPU1.LINK1, or the HSM CPU. All other LINKs have read-only access to these registers.

1. Start executing the application code from RAM or Flash.
2. Branch to or call the Flash configuration code (that writes the FRI registers) in RAM. This is required to properly flush the CPU pipeline before the configuration change. Any function that changes the FRI configuration must reside in RAM, and cannot execute from Flash memory using the same FRI.
3. Execute the Flash configuration code to configure the FRI registers (FRDCNTL, FLCLKCTL, FRIx_INTF_CTRL, and so on).
4. At the end of the Flash configuration code execution, wait nine cycles to allow the write instructions to propagate through the CPU pipeline. This must be done before the return-from-function call is made.
5. Return to the calling function residing in Flash or RAM, and continue execution.

Note

Flash read interfaces that do not include instruction fetch capability, such as FRI-3 and FRI-4, can be configured by code executing directly from Flash, provided that no data access to the covered Flash banks is being made. In such cases, verify that no current data access to the target Flash banks is being performed by placing the FRI configuration code in a separate function. Be sure to wait nine cycles to flush the CPU pipeline before branching back to regular application execution.

8.5 Flash Erase and Program

Flash memory can be programmed either by using the CCS Flash plug-in or by using the UniFlash application. If these methods are not feasible in an application, the Flash API can be used. The Flash memory can be programmed, erased, and verified only by using the Flash API library. These functions are written, compiled and validated by Texas Instruments. The Flash module contains a Flash state machine (FSM) to perform program and erase operations.

The recommended flow for programming Flash is:

Erase → Program → Verify

8.5.1 Flash Semaphore and Update Protection

Before program and erase operations can be performed, the currently running application must grab the Flash semaphore. The Flash semaphore is managed by the Safety and Security Unit, and can be grabbed by writing to the FLSEMREQ SSU register. For more information on how to use the Flash semaphore, see [Section 9.9](#).

The device security architecture also provides mechanisms to protect Flash banks and sectors from program and erase operations for safety and security. For more on these protection mechanisms, see [Section 9.9.1](#).

8.5.2 Erase

An erase operation causes all bits in the target Flash memory region to read as 1. A previously programmed Flash word (128 bits) must first be erased before new data can be programmed into the Flash word. The minimum memory size that can be erased in one operation is a Flash sector; single bits or words cannot be erased individually.

Erase operations are performed by the Flash State Machine (FSM) inside the Flash controller. All bits in each target sector are erased together, including data and ECC bits. Erase operations must be initiated using the Flash API, or a GUI front-end such as the Code Composer Studio™ Flash plug-in or UniFlash. The Flash API always erases sectors from both banks of an interleaved pair when an erase command is issued. When using the Flash API, erase is a non-blocking operation, so the application can perform other tasks while waiting for an erase command to complete.

Bank erase operations are also supported on this device. When performing bank erase, special sectors such as SECCFG and BANKMGMT are not included in the erase operation and must be erased separately.

Note

Because of the physical nature of Flash erase operations, the amount of time taken to complete an erase command gradually increases over time as more write-erase cycles are performed. There is also a lifetime limit on the number of write-erase cycles that are possible for each Flash Controller on a single device. For details on erase timing and write-erase cycle limits, see the device data sheet.

8.5.3 Program

A program operation modifies individual bits in a Flash word to read as 0 instead of 1. A program operation can only be performed on a previously erased bit. Flash programming must be aligned to 64-bit address boundaries, and each 64-bit word can only be programmed once per write/erase cycle.

The Flash State Machine provides a command to program the available user Flash regions: main Flash, SECCFG, and BANKMGMT. This command is also used to program the Error Correction Code (ECC) check bits. Program operations must be initiated using the Flash API, or a GUI front-end such as the Code Composer Studio™ Flash plug-in or UniFlash. The API provides the ability to automatically generate and program ECC check bits together with the data being programmed. Programming is a non-blocking operation, so the application can perform other tasks while waiting for programming to complete.

After programming, the user must perform a verify operation on the programmed Flash region using the API function `Fapi_doVerify()`, or using one of the Flash API GUI front-ends. This function verifies the Flash contents against the supplied data.

On this device, any of the primary application CPUs (CPU1, CPU3) or the HSM CPU can program any of the Flash banks on the device after grabbing the Flash semaphore. Secondary CPUs such as CPU2 do not have access to Flash memory. For security, programming access can be restricted to authorized code only by configuring the Flash update owner LINK and CPU in the SSU. Additionally, specific sectors can be completely blocked from program and erase using write/erase protection bits (WEPROT). For more information on these protection mechanisms, see [Section 9.9.1](#).

8.6 Read-While-Write Constraints

Table 8-2 showcases the constraints around performing a program, erase, and or verify operation simultaneously. The following constraints include:

- Possible to read from one bank pair while writing/erasing another bank pair, but not possible to read and write/erase the same bank pair.
- High-voltage operations (program, erase, and verify) using the same pump must be performed sequentially.
- Only one bank can be programmed, erased, and or verified at a time.

For example, an initiator (cpu1/cpu3, and so on) cannot read FLC1.B0/B1 and program/erase/verify the same bank pair simultaneously. However, the initiator can read FLC1.B0/B1 and program/erase/verify another bank pair (FLC1.B2/B3, FLC1.B4, and so on). Additionally, program/erase can only be performed by the initiator that owns the Flash semaphore. For example, if CPU1 holds the Flash semaphore, CPU1 must release the semaphore before CPU3 can perform a Flash program/erase operation.

Table 8-2. Read-While-Write Conditions

Read	Program / Erase / Verify	Supported?
FLC1.B0/B1	FLC1.B0/B1	No
FLC1.B0/B1	FLC1.B2/B3	Yes
FLC1.B0/B1	FLC1.B4	Yes
FLC1.B2/B3	FLC1.B0/B1	Yes
FLC1.B2/B3	FLC1.B2/B3	No
FLC1.B2/B3	FLC1.B4	Yes
FLC1.Bx	FLC2.Bx	Yes
FLC2.B0/B1	FLC2.B0/B1	No
FLC2.B0/B1	FLC2.B2/B3	Yes
FLC2.B2/B3	FLC2.B0/B1	Yes
FLC2.B2/B3	FLC2.B2/B3	No
FLC2.Bx	FLC1.Bx	Yes

8.7 Migrating an Application from RAM to Flash

To migrate an existing application that is configured to run from RAM to a Flash-based linker configuration, follow these steps:

1. Replace the RAM linker command file with a Flash linker command file. For examples of Flash-based linker command files, see the device_support\<device>\common\cmd directory.
2. When modifying the Flash-based linker command file, be sure to map any initialized sections to Flash memory regions.
3. Make sure the boot mode pins are configured for Flash boot. This tells the boot ROM to redirect execution to the application programmed into Flash memory after boot code execution is complete. For more information on boot mode configuration, see *Detailed Description > Device Boot Modes* in the device data sheet.
4. When the device is configured for Flash boot, the boot ROM redirects execution to the Flash entry point location (defined as BEGIN in TI-provided Flash linker command files) at the end of boot code execution. Make sure there is a branch instruction at the Flash entry point to your code initialization (for example, _c_int00) function. In the C2000Ware examples, the entry point code is specified in the codestartbranch.asm file.
5. To achieve best performance for Flash execution, configure the Flash wait states as per the device operating clock frequency, as specified in the device data sheet. In addition, enable prefetch mode and data cache mode. Calling the Flash_initModule() driverlib function achieves these steps. Note that code that initializes the Flash module must execute from a RAM location. This is accomplished by assigning the Flash initialization function to the .TI.ramfunc section. In the linker command file, map this section to Flash for load, and RAM for execution. The example cmd files provided in the [F29x Software Development Kit \(F29-SDK\)](#) show how to do this correctly.
6. For any functions that require 0- or 1-wait state performance, be sure to map to RAM for execution in the linker command file, similar to the Flash initialization function. The .TI.ramfunc section in the TI-provided Flash linker command files accomplishes this purpose.
7. Align all code and data sections to 128-bit address boundaries when mapping to Flash memory, using the ALIGN directive in the linker command file.
8. For EABI executable formats, define all uninitialized sections mapped to RAM as NOINIT sections (using the directive "type=NOINIT") in the linker command file.
9. Be sure to program ECC bits correctly for the Flash application image. Keep the AutoEccGeneration option enabled in the Code Composer Studio Flash Plugin or UniFlash GUI.

8.8 Flash Registers

This section describes the Flash Module Registers.

8.8.1 FLASH Base Address Table

Table 8-3. FLASH Base Address Table

Structure	DriverLib Name	Base Address	Frame Applicable	CPU1	CPU2	CPU3	RTDMA1	RTDMA2	HSM	Pipeline Protected
FLASH_CMD_REGS_FLC1	FLASHCONTROLLER1_BASE	0x3010_0000	-	YES	-	YES	-	-	YES	YES
FLASH_CMD_REGS_FLC2	FLASHCONTROLLER2_BASE	0x3011_0000	-	YES	-	YES	-	-	YES	YES
FRI_CTRL_REGS[†]	FRI1_BASE	0x301D_0000	-	YES	YES	YES	-	-	YES	YES

- (1) Registers writable by CPU1.LINK0, CPU1.LINK1, CPU1.LINK2 only. All CPUs can read all registers in all LINKs. Debug write access only allowed if Zone0 or Zone1 are enabled for full debug by all CPUs. Debug reads always allowed. Register Read/Write access by HSM.

8.8.2 FLASH_CMD_REGS_FLC1 Registers

Table 8-4 lists the memory-mapped registers for the FLASH_CMD_REGS_FLC1 registers. All register offset addresses not listed in Table 8-4 should be considered as reserved locations and the register contents should not be modified.

Table 8-4. FLASH_CMD_REGS_FLC1 Registers

Offset	Acronym	Register Name
1D0h	CMDWEPROTA	Command Write Erase Protect A Register
1D4h	CMDWEPROTB	Command Write Erase Protect B Register
210h	CMDWEPROTNM	Command Write Erase Protect Non-Main Register
3D0h	STATCMD	Command Status Register

Complex bit access types are encoded to fit into small table cells. Table 8-5 shows the codes that are used for access types in this section.

Table 8-5. FLASH_CMD_REGS_FLC1 Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value

8.8.2.1 CMDWEPROTA Register (Offset = 1D0h) [Reset = 00000000h]

CMDWEPROTA is shown in [Figure 8-6](#) and described in [Table 8-6](#).

Return to the [Summary Table](#).

Command WriteErase Protect A Register

This register allows the first 32 sectors of the main region to be protected from program or erase, with 1 bit protecting each sector. If the main region size is smaller than 32 sectors, then this register provides protection for the whole region.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

In addition, this register is used to aggregate masking for sectors that do not require additional erase pulses during bank erase operations, and will be written to all 1 after the completion of all flash wrapper commands.

Bit	Field	Type	Reset	Description
31-0	VAL	R/W	FFFFFFFFh	Each bit protects 1 sector. bit [0]: When 1, sector 0 of the flash memory will be protected from program and erase. bit [1]: When 1, sector 1 of the flash memory will be protected from program and erase. :: bit [31]: When 1, sector 31 of the flash memory will be protected from program and erase. 0h = Minimum value of [VAL] FFFFFFFFh = Maximum value of [VAL]

8.8.2.2 CMDWEPROTB Register (Offset = 1D4h) [Reset = 00000000h]

CMDWEPROTB is shown in [Figure 8-7](#) and described in [Table 8-7](#).

Return to the [Summary Table](#).

Command WriteErase Protect B Register

This register allows main region sectors to be protected from program and erase. Each bit corresponds to a group of 8 sectors.

There are 3 cases for how these protect bits are applied:

1. Single-bank system:

In the case where only a single flash bank is present, the first 32 sectors are protected via the CMDWEPROTA register. Thus, the protection given by the bits in CMDWEPROTB begin with sector 32.

2. Multi-bank system, Bank 0:

When multiple flash banks are present, the first 32 sectors of bank 0 are protected via the CMDWEPROTA register. Thus, only bits 4 and above of CMDWEPROTB would be applicable to bank 0. The protection of bit 4 and above would begin at sector 32. Bits 3:0 of WEPROTB are ignored for bank 0.

3. Multi-bank system, Banks 1-N:

For banks other than bank 0 in a multi-bank system, CMDWEPROTA has no effect, so the bits in CMDWEPROTB will protect these banks starting from sector 0.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

In addition, this register is used to aggregate masking for sectors that do not require additional erase pulses during bank erase operations, and will be written to all 1 after the completion of all flash wrapper commands.

Figure 8-7. CMDWEPROTB Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

8.8.2.3 CMDWEPROTNM Register (Offset = 210h) [Reset = 00000000h]

CMDWEPROTNM is shown in [Figure 8-8](#) and described in [Table 8-8](#).

Return to the [Summary Table](#).

Command WriteErase Protect Non-Main Register

This register allows non-main region region sectors to be protected from program and erase. Each bit corresponds to 1 sector.

This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.

In addition, this register is used to aggregate masking for sectors that do not require additional erase pulses during bank erase operations, and will be written to all 1 after the completion of all flash wrapper commands.

Bit	Field	Type	Reset	Description
31-13	RESERVED	R	0h	Reserved
12	FAILMISC	R	0h	Command failed due to error other than write/erase protect violation or verify error. This is an extra bit in case a new failure mechanism is added which requires a status bit. 0h = No Fail 1h = Fail
11-9	RESERVED	R	0h	Reserved
8	FAILINVDATA	R	0h	Program command failed because an attempt was made to program a stored 0 value to a 1. 0h = No Fail 1h = Fail
7	FAILMODE	R	0h	Command failed because a bank has been set to a mode other than READ. Program and Erase commands cannot be initiated unless all banks are in READ mode. 0h = No Fail 1h = Fail
6	FAILILLADDR	R	0h	Command failed due to the use of an illegal address 0h = No Fail 1h = Fail
5	FAILVERIFY	R	0h	Command failed due to verify error 0h = No Fail 1h = Fail
4	FAILWEPROT	R	0h	Command failed due to Write/Erase Protect Sector Violation 0h = No Fail 1h = Fail
3	RESERVED	R	0h	Reserved
2	CMDINPROGRESS	R	0h	Command In Progress 0h = Complete 1h = In Progress

Table 8-15. STATCMD Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	CMDPASS	R	0h	Command Pass - valid when CMD_DONE field is 1 0h = Fail 1h = Pass
0	CMDDONE	R	0h	Command Done 0h = Not Done 1h = Done

8.8.4 FRI_CTRL_REGS Registers

Table 8-16 lists the memory-mapped registers for the FRI_CTRL_REGS registers. All register offset addresses not listed in Table 8-16 should be considered as reserved locations and the register contents should not be modified.

Table 8-16. FRI_CTRL_REGS Registers

Offset	Acronym	Register Name	Protection
0h	REVISION	IP Revision Register	
10h	FRDCNTL	Flash Read Control Register	PARITY_PROTECTED
14h	FRDCNTL_LOCK	Flash Read Control Lock Register	PARITY_PROTECTED
18h	FRDCNTL_COMMIT	Flash Read Control Commit Register	PARITY_PROTECTED
30h	FRI1_INTF_CTRL	Flash Read Interface 1 Control Register	PARITY_PROTECTED
34h	FRI1_INTF_CTRL_LOCK	Flash Read Interface 1 Control Lock Register	PARITY_PROTECTED
38h	FRI1_INTF_CTRL_COMMIT	Flash Read Interface 1 Control Commit Register	PARITY_PROTECTED
3Ch	FRI1_INTF_CLR	Flash Read Interface 1 Clear Register	PARITY_PROTECTED
40h	FRI2_INTF_CTRL	Flash Read Interface 2 Control Register	PARITY_PROTECTED
44h	FRI2_INTF_CTRL_LOCK	Flash Read Interface 2 Control Lock Register	PARITY_PROTECTED
48h	FRI2_INTF_CTRL_COMMIT	Flash Read Interface 2 Control Commit Register	PARITY_PROTECTED
4Ch	FRI2_INTF_CLR	Flash Read Interface 2 Clear Register	PARITY_PROTECTED
50h	FRI3_INTF_CTRL	Flash Read Interface 3 Control Register	PARITY_PROTECTED
54h	FRI3_INTF_CTRL_LOCK	Flash Read Interface 3 Control Lock Register	PARITY_PROTECTED
58h	FRI3_INTF_CTRL_COMMIT	Flash Read Interface 3 Control Commit Register	PARITY_PROTECTED
5Ch	FRI3_INTF_CLR	Flash Read Interface 3 Clear Register	PARITY_PROTECTED
60h	FRI4_INTF_CTRL	Flash Read Interface 4 Control Register	PARITY_PROTECTED
64h	FRI4_INTF_CTRL_LOCK	Flash Read Interface 4 Control Lock Register	PARITY_PROTECTED
68h	FRI4_INTF_CTRL_COMMIT	Flash Read Interface 4 Control Commit Register	PARITY_PROTECTED
6Ch	FRI4_INTF_CLR	Flash Read Interface 4 Clear Register	PARITY_PROTECTED
70h	PARITY_TEST	Parity Test Enable	
74h	PARITY_TEST_LOCK	Parity Test Lock Register	
78h	PARITY_TEST_COMMIT	Parity Test Commit Register	

Complex bit access types are encoded to fit into small table cells. Table 8-17 shows the codes that are used for access types in this section.

Table 8-17. FRI_CTRL_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1S	W1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

8.8.4.1 REVISION Register (Offset = 0h) [Reset = 00000000h]

REVISION is shown in [Figure 8-14](#) and described in [Table 8-18](#).

Return to the [Summary Table](#).

IP Revision Register

Figure 8-14. REVISION Register

Table 8-19. FRDCNTL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-28	RESERVED	R	0h	Reserved
27-24	TRIMENGRWAIT	R/W	8h	Read waitstates of Trim and ENGR sectors. These bits indicate how many waitstates are added to a flash read/fetch access. The TRIMENGRWAIT value can be set anywhere from 1 to 0xF (zero waitstates is not supported). For a flash access from TRIM or ENGR sectors, data is returned in TRIMENGRWAIT+1 SYSCLK cycles. Note: The required wait states for each SYSCLK frequency can be found in the device data manual. Reset type: XRSn
23-16	RESERVED	R	0h	Reserved
15-12	RESERVED	R	0h	Reserved
11-8	RWAIT	R/W	4h	Read waitstates. These bits indicate how many waitstates are added to a flash read/fetch access. The RWAIT value can be set anywhere from 1 to 0xF (zero waitstates is not supported). For a flash access to any non-TRIM or ENGR section, data is returned in RWAIT+1 SYSCLK cycles. Note: The required wait states for each SYSCLK frequency can be found in the device data manual. Reset type: XRSn
7-0	RESERVED	R	0h	Reserved

8.8.4.3 FRDCNTL_LOCK Register (Offset = 14h) [Reset = 00000000h]

FRDCNTL_LOCK is shown in [Figure 8-16](#) and described in [Table 8-20](#).

Return to the [Summary Table](#).

Chapter 9 Safety and Security Unit (SSU)

This chapter describes the features and operation of the Safety and Security Unit (SSU). The SSU is the central element of the security architecture. The SSU provides run-time safety and security for the application CPU subsystems, and governs debug access to various resources on the chip. The SSU also provides hardware infrastructure for managing Flash firmware update operations, using the Firmware-Over-The-Air (FOTA) or Live Firmware Update (LFU) processes.

9.1 Introduction

At the heart of the architecture is the Safety and Security Unit (SSU). The SSU acts as a firewall between the C29x CPUs and the memory and peripherals. The primary role of the SSU is to enforce user access protection policy every time the C29x CPU performs accesses to peripherals and memory on the chip. In addition, the SSU governs debug access and Flash Controller operations in the C29x application subsystem (note: the SSU has no control over the HSM Flash, or any other HSM resources). While the Hardware Security Module (HSM) provides cryptographic services and governs authentication, secure boot and secure key/code provisioning, the SSU is responsible for run-time safety and security protections in application CPU subsystems. Both the HSM and SSU govern debug access authorization; both must enable access to a specific resource for debug to be authorized. For more information on HSM and SSU complementary features, refer to [Table 39-1](#).

Note

While the SSU acts as a firewall between the C29x CPUs and the memory and peripherals, the SSU access filters do not govern RTDMA operations. RTDMA is an independent bus initiator. For more information on how the SSU interfaces with RTDMA refer to [Section 12.9.2](#)

A simplified view of the real-time security architecture in this device is shown in [Figure 9-1](#).

Figure 9-1. Real-Time Security Architectural Block Diagram

9.1.3 System SSU Configuration Example

The SSU is tightly coupled to the C29x CPUs and the C29x Flash Controllers. Each C29x CPU is designed to support hardware function isolation and protections using memory protection identifiers (LINKs), safety and security isolation contexts (STACKs), and debug access ZONES. An example of a system SSU configuration, showing the relationship between access protection ranges, LINKs, STACKs and ZONES is shown in [Figure 9-2](#). When the CPU requests an instruction fetch, the SSU first decodes the instruction address to a LINK, STACK, and ZONE, and then passes that information back to the CPU along with the fetched data. The CPU retains this security context information together with the instruction throughout the execution pipeline, and passes the context along to the SSU when making a data memory read or write access.

Each LINK consists of one or more regions of executable code, defined by the memory ranges in which the code resides, and is typically associated with a specific task or software module. The Access Protection Ranges, or APRs, are the basic unit of memory protection. Each APR has a start address and an end address, and can be associated with executable code (associating that code with a specific LINK), or can cover data or peripheral memory. Each APR then defines read and write access permissions for every LINK available on the CPU, enabling dynamic memory access permissions that automatically change based on which code is accessing the memory region. Each LINK is associated with one STACK. Each STACK is associated with a physically distinct and separate stack pointer in the CPU for secure code isolation. Finally, every STACK is associated with one device-level ZONE that governs debug and firmware update security.

These concepts are explained in detail in the following sections.

Figure 9-2. System SSU Configuration Example

9.2 Access Protection Ranges

The SSU defines memory protections using Access Protection Ranges (APRs), governing CPU access to on-chip memories, peripherals, and external memories. There are a total of 64 APRs available per CPU. Each APR specifies the following:

- Starting address
- Ending address
- Associated code execution LINK
- Code execution permissions
- Read and write permissions per LINK
- Inherited permissions
- Lock and commit settings

Access protection ranges are defined using the APx registers. The access protection registers are loaded at boot time, but can be modified afterward by code running with security root privileges. Before performing a CPU access to any memory location, the user must make sure to define an access protection range that includes that location. In addition, access protection range definitions must not overlap each other. If a CPU access is performed to a memory location that is covered by zero or more than one access protection range, the SSU generates a fault signal to the CPU, which then forwards the error to the Error Aggregator module.

Each standard APR has a start address, defined in the APx_START register, and an end address, defined in the APx_END register. Every AP range is aligned to a 4KB memory boundary, so the lower 12 bits of each APx_START register are hardcoded to 0, and the lower 12 bits of each APx_END register are hardcoded to 0xFFF. The regular AP ranges can address the first 2GB of the device address space, covering on-chip memories or peripheral memory-mapped registers. Each AP range has a maximum size of 16MB. The MEMTYPE field in the start address indicates what type of memory is covered by the AP range. Note that the MEMTYPE bits are the same as the CPU address bits per the device memory-map; there is no special handling of these bits in the SSU. Simply writing the range's start address to APx_START is sufficient.

Access permissions for an APR are configured using the APx_ACCESS register. This register defines, for each LINK, whether to grant no access permission, read-only permission, or read/write permission.

APRs also include the following configuration options:

- Access Protection Disable, by writing to the APx_CFG.APD bit.
- Execute Enable/Disable, by writing to the APx_CFG.XE bit. This setting defines the APR as a code/program memory region, and any code instruction that is fetched from the memory range is associated with the LINK defined in the APx_CFG.LINKID field.

The first two AP ranges (AP0 and AP1) are extended AP ranges. These special ranges have address ranges spanning the full 4GB address space available, and as such can cover extended memory ranges such as external memories connected using the EMIF interface. The start and end addresses of these extended AP ranges are defined in the APx_START_EXT and APx_END_EXT registers. Like standard AP ranges, the extended AP ranges must also be aligned to 4KB address boundaries.

Note

Not all memory regions can be configured for protection by an APR. Certain peripherals, memory regions and bridges are governed by system-level hardcoded protections. For a detailed memory map showing which memory regions can be APR-protected, see the device data sheet.

9.2.1 Access Protection Inheritance

An AP range can be configured to inherit protection settings from a specific LINK's caller. The APx_CFG.APILINK register field specifies the LINKID which inherits permissions for access to Access Protection Range APx. The C29x CPU sets DSTS.CLINK to the current LINK's caller LINKID whenever a protected call is performed. Whenever code belonging to the LINKn specified in APx_CFG.APILINK performs an access to memory within APx, the access permissions granted to LINKn match the access permissions for LINKn's caller.

(as identified by CLINK on the data access request). The access protection inheritance feature is enabled by setting APx_CFG.APILINKE to 1.

Access protection inheritance is useful for maintaining memory protection when using common or utility functions such as *memcpy*. Without inheritance, an unauthorized LINK can access data memory covered by APx by simply calling a shared memory function with direct read or write access to APx. However, when APx_CFG.APILINKE is set to 1 and APx_CFG.APILINK is defined to be the LINK associated with the common code functions, then the shared function is imputed the same permissions as the LINK that called the shared function. An illustration of how access protection inheritance enables the sharing of common code functions between different LINKs is shown in Figure 9-3.

Figure 9-3. Access Protection Inheritance Example

Note

In the C29x CPU, DSTS.CLINK is only updated by a protected function call, and is not updated during a regular function call or branch. For LINKs within the same STACK, branches and function calls must be executed using protected call instructions for the access protection inheritance feature to work correctly.

9.3 LINKs

LINKs form the basis for context-sensitive memory protection. Each LINK represents one or more regions of executable code, and determines what data memory ranges (APRs) can be accessed by that code. Every code instruction that executes on the CPU has an associated LINK ID, which is assigned based on the memory region the instruction was fetched from. Thus, memory protections across the entire SoC can be automatically configured for each instruction at execution time, eliminating the need for software-based MPU reconfiguration.

The APx_CFG.LINKID register defines the execution LINK for all code that the CPU fetches from the APx memory address range. In addition, to enable code execution from an AP range, the user must configure the APx_CFG.XE (execution enable) bit. For data-only LINKs, make sure to set the XE bit to zero to preserve

code safety. The SSU inputs the LINKID to the CPU when an instruction is fetched, and the CPU outputs the LINKID to the SSU whenever the CPU performs a data access to a memory location. The SSU compares the requesting LINKID to the access permissions for the APR containing the target memory address by examining the corresponding APx_ACCESS.LINKy register. If the permissions defined in the APx_ACCESS.LINKy do not authorize the requesting LINKID, then the SSU generates a fault to the CPU. If the memory region containing the address is governed by hardcoded protections (for example, writable by LINK0, LINK1 or LINK2 only), the SSU checks the requested operation against the hardcoded protection, and generates a fault to the CPU if unauthorized. See [Figure 9-4](#) for an illustration of how the SSU filters data access requests from the CPU using associated LINKIDs.

There are 16 LINKs per CPU. The SSU predefines and reserves the following special roles for the first three links:

- LINK0 is reserved for internal use and cannot be configured by the user.
- LINK1 is primarily used for TI and user boot loaders, but can also be used for user run-time code.
- LINK2 is the primary user LINK. CPU1.LINK2 is the Security Root LINK (SROOT).

All other LINKs are secondary user LINKs, and can be defined by the user application as required. LINK0, LINK1 and LINK2 have special hard-coded permissions. For more info, see [Section 9.13](#).

Note

LINK2 has privileges to change the protection policy during runtime, unless LINK2 is locked and committed. During software development, LINK2 must be treated as secure code with appropriate analysis and testing of LINK2 code to harden the code against attacks.

Figure 9-4. SSU-CPU Tightly Coupled Interface

9.4 STACKS

STACKs isolate code execution contexts from each other. Each STACK has a dedicated stack pointer in the CPU, and a dedicated set of CPU registers, and provides hardware safety and security isolation of code from other STACKs. Every LINK belongs to one and only one STACK, but a STACK can contain multiple LINKs. For CPU execution to cross from a LINK associated with one STACK to a LINK associated with another STACK, the code must execute special instructions that preserve data safety during context switching.

To specify which STACK a LINK belongs to, configure the LINKx_CFG field/register in the SSU configuration.

Like LINKs, the SSU passes the STACKID to the CPU during instruction fetch, and the CPU outputs the instruction STACKID to the SSU when performing data accesses.

Each CPU has a total of 8 STACKs. The SSU predefines and reserves the first three stacks as follows:

- STACK0 is reserved for internal use, and is always associated with LINK0 only.
- STACK1 is primarily used for boot loaders, but can also be used for user application code. STACK1 is always associated with LINK1 only.
- STACK2 is the primary user stack. STACK2 is associated with LINK2, and can be associated with other secondary user LINKs depending on the configured user protection policy.

STACK3 and above are secondary user STACKs, and can be defined by the user application as required.

9.5 ZONES

Each ZONE governs debugger access to the system, and as well as firmware update permissions. ZONES determine what permissions an external user or programmer has to download or program code, perform firmware updates, and debug the system. While AP ranges, LINKs and STACKs are independently defined per CPU, ZONES span the entire device, excluding the HSM (which is not governed by the SSU).

Each device has a total of 4 available ZONES. ZONE0 is reserved for TI internal use, and is always associated with STACK0/LINK0. The primary user ZONE is ZONE1. ZONE1 is always associated with STACK1 and STACK2, but can include other STACKs depending on user configuration. ZONE2 and ZONE3 are secondary user ZONES, and can be associated with STACK3 and other secondary user STACKs.

To configure which ZONE a STACK is associated with, write to the STACKx_CFG field/register in the SECCFG sector.

Each user ZONE has three possible operating permission levels:

- **Debug not allowed**
- **Partial debug allowed:** This mode permits the user to debug CPU execution (halt, resume, view registers), but prevents read/write access to memories.

Note

Flash Plugin will not be able to run when partial debug is enabled for ZONE1.

- **Full debug allowed:** This mode enables full debug capability.

In partial debug mode, the SSU blocks debugger access to various registers, as described in [Section 9.14](#). For information on how to enable debug for user ZONES, see [Section 9.12](#). The SSU_GEN_REGS.DEBUG_STAT register indicates the current active debug permission level for each user ZONE.

A debug ZONE inherits memory access permissions from the sum total of all LINKs that are associated with the ZONE. This means that if a ZONE is enabled for full debug, then the debugger's ability to read or write any memory address depends on whether the access protection range covering that address gives permission to any LINK belonging to the ZONE.

Note

If an AP range has the APx_CFG.XE bit set (that is, defined as a code region), and the LINKID of the AP region belongs to a ZONE that is enabled for full debug, then the debugger is given read and write access to the AP range—even if no associated LINKs have read/write access to the AP range.

9.6 SSU-CPU Interface

The SSU is tightly coupled with each CPU during different phases of execution. When the CPU requests an instruction fetch, the SSU first decodes the instruction address to a LINK, STACK, and ZONE, and passes that information back to the CPU along with the fetched data. The CPU retains this security context information together with the instruction throughout the execution pipeline, and passes the context along to the SSU when making a data memory read or write access. Within the SSU, the data access filter logic uses the LINKID and CLINK associated with the instruction to qualify each memory access request and determine whether to permit the access.

The SSU provides a CPUID register, can be read by the application to determine which CPU the application is executing on. Additionally, the decoder logic can be used to determine which LINK, STACK and ZONE a particular code instruction belongs to, by writing the instruction's address to the DECODER_ADDR_IN register and reading the DECODER_OUT register.

Figure 9-4 illustrates the tightly-coupled interface between the SSU and the C29x CPU.

While debugging, the CURRLINK and CURRSP fields of the ISTS, CPU Core Register, can also be monitored to determine the current LINK and STACK POINTER of execution. More information on these fields is provided in the [C29x CPU Reference Guide](#).

Note

If a peripheral is protected from access by the CPU, the protection does not prevent access to reach the peripheral. Access is blocked by the return path, and SSU generates an error to the CPU at that time. Since a read request still reaches the peripheral, this changes the status of the peripheral in cases where there is a FIFO pointer or a read clear flag status. Affected peripherals include I2C, SPI, CAN, PMBUS, SENT, FSI, and UART. Extra software considerations need to be implemented to check for possible peripheral reads when utilizing the SSU such that application usage of the peripheral is not impacted.

9.6.1 SSU Operation in Lockstep Mode

When lockstep mode is enabled on a CPU pair (for example, CPU1 and CPU2), the SSU enforces protections based on the security policy for CPU1. Security sideband signals for LINK, STACK, ZONE and protection fault status are forwarded to both CPUs in lockstep. For a description of functional safety requirement compliance in this mode, see the device safety manual.

Note

Flash programming and erase operations cannot be performed in lockstep. To implement a functional safety strategy for Flash programming, incorporate verify reads of the programmed Flash content after programming. For more information, see the device safety manual.

9.7 SSU Operation Modes

The SSU has three modes of operation: SSUMODE1, SSUMODE2, and SSUMODE3. Devices ship from the TI factory in SSUMODE1 mode. Once safety and security has been integrated into the development project, configure the SSU to SSUMODE2 to enable safety/code isolation features, and then configure to SSUMODE3 when development is finalized for production programming to enable full security. If safety and security features are not desired in the target application, the device can be left in SSUMODE1; and if safety features are desired but not security, the device can be left in SSUMODE2.

In SSUMODE3:

1. All safety and security features of the SSU are active and enforced.
2. All user ZONES (ZONE1, ZONE2, and ZONE3) are disabled for debug by default. Each ZONE must be authorized as configured to enable partial or full debug access.
3. JTAG and debug access are governed by debug authorization settings.
4. Debugger accesses to LINK1 RAM and LINK1 Flash are only permitted when ZONE1 is enabled for full debug.

In SSUMODE2:

1. JTAG is enabled;
2. All user ZONES (ZONE1, ZONE2, and ZONE3) are enabled for full debug;
3. CPU1.LINK1 and/or any C29x CPU debug access is allowed to:
 - a. Write to the RAMOPENFRC and RAMOPENCLR registers
 - b. Write to the SSU APx registers
 - c. Update all Flash SECCFG sectors
 - d. Update all Flash MAIN sectors

In SSUMODE1:

1. All characteristics of SSUMODE2 are present;
2. User access protection (AP) regions are disabled for all CPUs;
3. The entire memory map of the device, excluding ROM, RAMOPENed RAM and hard-coded RAM and Flash memory regions, is mapped to run as LINK2;
4. The entire memory map of the device, excluding ROM, RAMOPENed RAM and hardcoded RAM and Flash memory regions, is accessible by all LINKs.

Both SSUMODE1 and SSUMODE2 permit generic programmers to program Flash memory. However, in SSUMODE3, the user must explicitly give LINK1 Flash memory write permissions to enable any kind of bootloader/Flash kernel to program the Flash.

SSUMODE must be configured by programming SSU_MODE location in [Section 9.8.2](#). The value of SSUMODE is loaded from SECCFG into the SSUMODE register during boot. The value of SSUMODE cannot be changed during run time.

Note

SSUMODE is a 32-bit register. All 32 bits must be programmed into the SECCFG field, including leading zeroes, for the device to boot successfully.

Although all user ZONES are enabled for full debug in SSUMODE2, this does not automatically give the debugger full access to device memory. Every debug ZONE inherits permissions from the LINKs belonging to that ZONE, and these permissions are configured in the AP ranges. If there is no AP range covering a memory address, debugger accesses to that memory address are blocked in SSUMODE2. To enable debugger access to a memory region in SSUMODE2, make sure to configure an AP range covering the region, and grant at least one LINK the access level required for the debugger to access the memory region.

9.8 Security Configuration and Flash Management

Each Flash bank in the C29x application subsystem has two regions that contain information which configures the SSU: SECCFG and BANKMGMT. These regions are separate from the main Flash sectors, and do not count against the stated available Flash memory for application use. SECCFG is used for storing the SSU configuration, also known as the User Protection Policy (UPP). BANKMGMT is used for managing Flash updates using the Firmware-Over-The-Air (FOTA) or Live Firmware Update (LFU) mechanisms.

The configuration settings stored in these Flash regions are loaded into the SSU registers at device startup. Most UPP settings cannot be modified by the application during run time. To modify the UPP, the application or connected debugger must erase and re-program SECCFG with the desired settings. See [Section 9.9](#) for details on protection mechanisms to prevent unauthorized updates to these sectors. [Section 9.14](#) contains details on run-time access permissions for individual SSU registers.

Texas Instruments recommends using the SysConfig tool, included as part of the device [F29x-SDK](#), to configure the SSU and generate user security settings. This tool provides an easy-to-use graphical user interface to create application security partitions and protection definitions, and automatically generates linker command files, a SECCFG image, and header files to be included in the user application. For more information on the SSU Tool within SysConfig refer to the app note, [Implementing Run-Time Safety and Security with the C29x Safety and Security Unit](#).

Note

An accurate SECCFG CRC value is required for the device to boot successfully. To avoid device boot problems due to inaccurate CRC computation, use the SysConfig tool to build the SECCFG image and auto-compute the associated CRC.

Note

If SysConfig Tool is only used to configure the SSU then only the following SysConfig generated files need to be incorporated into user project: linker.cmd, ssu_config.c, ssu_config.h, and seccfg.c

9.8.1 BANKMGMT Sectors

The BANKMGMT region of each bank pair contains three fields that are used to manage bank status and firmware updates:

1. **BANK_STATUS[63:0]** (Offset 0x00): This field specifies whether the bank contents are currently valid or invalid. A valid bank pair has a status value of 0x55555555_55555555. If both banks are inactive, the device is unable to execute Flash code and can fail to boot. If both banks have valid active statuses, then the current active bank is determined by BANK_UPDATE_CTR.
2. **BANK_UPDATE_CTR[63:0]** (Offset 0x08): This is a 64-bit *decrementing* counter value that is used to determine the most recent firmware revision. The counter has a value of 0xFFFFFFFF_FFFFFFFF when shipped from the TI factory. When both bank pairs have valid status values, the BANK_UPDATE_CTR for each bank pair is compared against the other to determine the most recent firmware revision. The bank pair with the lower counter value is determined to be the most recent revision.
3. **BANKMODE[63:0]** (Offset 0x10): This field only exists in FLC1 BANKMGMT regions (for CPU1). The BANKMODE field configures the device bankmode and is loaded into the SSU_GEN_REGS.BANKMODE register at device boot. After BANKMODE is configured, the boot ROM then reads the value of each bank pair's BANK_UPDATE_CTR to determine whether CPUxSWAP is enabled.

The BANKMGMT region is best programmed and configured using the Flash API and TI Flash tools, such as the CCS Flash Plugin or UniFlash. To avoid misconfiguration resulting in an unbootable device, do not allocate data directly into the BANKMGMT region in the application image/.out file.

The following security restrictions apply to updates of the BANKMGMT region:

- In SSUMODE1, all code running from any LINK has permission to update the BANKMGMT sectors, since ZONE1 is enabled for full debug. This enables ease of code development.

- In SSUMODE2, all code running from any LINK has permission to update the BANKMGMT sectors, since ZONE1 is enabled for full debug.
- In SSUMODE3, only the SECCFG update owner defined in SECCFG_UPDATE_CFG has permission to update BANKMGMT sectors. In addition, SECCFG_UPDATE_CFG.UPDATE_EN must be set to 0xC to enable updates to BANKMGMT when operating in SSUMODE3.

9.8.2 SECCFG Sectors

SECCFG sectors are a portion of Flash memory designated for storing the SSU user configuration, or User Protection Policy (UPP). The following rules apply to SECCFG sectors:

- Each SECCFG sector is 2KB in size.
- Each CPU pair (for example, CPU1/CPU2) has an associated active SECCFG sector, and a reserve SECCFG sector.
- All code banks are interleaved in pairs to enable 256-bit instruction fetches. As a result, the effective SECCFG sector size is 4KB, due to the interleaving of the two banks. However, the SECCFG image size is 2KB; the remaining half is unused.

[Table 9-1](#) shows the mapping of SECCFG sectors to CPU addresses. Each CPU has an active SECCFG start address, and an alternate (reserve) SECCFG start address. Reserve SECCFG sectors are used for Flash updates, and are swapped with the active sector (together with all other bank sectors) when the firmware update process is complete. The locations of these addresses in the CPU memory map depend on the active settings in the BANKMODE and BANKMAP registers. The SECVALID register, in combination with the BANKMODE register, defines which address holds the valid SECCFG information for a CPU pair. The CPUxSWAP fields in the BANKMAP register specify which bank contains this information; however, the address range does not change even if CPUxSWAP changes.

The values of BANKMODE and BANKMAP in the Flash BANKMGMT sectors are automatically loaded into the SSU registers at boot time. After determining the active SECCFG sector, the device then loads the User Protection Policy from the active SECCFG sector into the SSU registers.

[Table 9-2](#) shows a map of the SECCFG sector contents as mapped to SSU registers.

9.8.3 SECCFG Sector Address Mapping

Table 9-1 shows the mapping of physical bank SECCFG sectors to CPU addresses, depending on the Flash bank mode and swap configuration.

Table 9-1. SECCFG Address Mapping

Bank Mode	CPUxSWAP	Region	CPU1/CPU2 Bank	CPU1 Address	CPU2 Address	CPU3 Bank	CPU3 Address
MODE 0		Active	FLC1.B0/B1	0x10D8 1000	0x10D8 1800	FLC2.B0/B1	0x10D8 9000
		Update	FLC1.B2/B3	0x10D8 5000	0x10D8 5800	FLC2.B2/B3	0x10D8 D000
MODE 1	SWAP = 0	Active	FLC1.B0/B1	0x10D8 1000	0x10D8 1800	FLC2.B0/B1	0x10D8 5000
		Update	FLC1.B2/B3	0x10D9 9000	0x10D9 9800	FLC2.B2/B3	0x10D9 D000
	SWAP = 1	Active	FLC1.B2/B3	0x10D8 1000	0x10D8 1800	FLC2.B2/B3	0x10D8 5000
		Update	FLC1.B0/B1	0x10D9 9000	0x10D9 9800	FLC2.B0/B1	0x10D9 D000
MODE 2		Active	FLC1.B0/B1	0x10D8 1000	0x10D8 1800	FLC2.B0/B1	0x10D9 1000
		Update	FLC1.B2/B3	0x10D8 5000	0x10D8 5800	FLC2.B2/B3	0x10D9 5000
MODE 3	SWAP = 0	Active	FLC1.B0/B1	0x10D8 1000	0x10D8 1800	FLC2.B0/B1	0x10D9 1000
		Update	FLC1.B2/B3	0x10D9 9000	0x10D9 9800	FLC2.B2/B3	0x10D9 D000
	SWAP = 1	Active	FLC1.B2/B3	0x10D8 1000	0x10D8 1800	FLC2.B2/B3	0x10D9 1000
		Update	FLC1.B0/B1	0x10D9 9000	0x10D9 9800	FLC2.B0/B1	0x10D9 D000

9.8.4 SECCFG Sector Memory Map

Table 9-2 shows the mapping of various SSU registers and configuration values to SECCFG sector address locations. The 'CPUs' column indicates which files of corresponding CPU's SECCFG Sectors are analyzed by TI ROM and copied into respective SSU Registers.

Table 9-2. SECCFG Sector Memory Map

⁽¹⁾The update counter in SECCFG Flash Sector is not used by Flash APIs or TI BootROM, user should leave as-is. Instead, a single SECCFG Counter value for CPU pair (ex. CPU1 and CPU2) is used and located at offset 0xFF0 (outside of CRC range). This counter at offset 0xFF0 is automatically handled by Flash API/Flash Plugin when SECCFG is programmed and ROM uses this value to determine the active SECCFG sector.

⁽²⁾ The value of this field will not be stored in a register. ROM will interpret value in SECCFG and if enabled, execute LPOST at indicated PLL frequency.

⁽³⁾The value of this field will not be stored in a register. ROM will interpret value in SECCFG and if enabled, use XTAL during boot process.

⁽⁴⁾The value of this field will not be stored in a register. ROM will interpret value in SECCFG and setup the designated GPIO as the Error Status pin (setup qual mode as ASYNC, pad config as standard type, and multiplex option to route internal ERRORSTS signal from output of ESM to physical GPIO).

⁽⁵⁾The value of this field will not be stored in a register. This field is used to indicate the validity of SECCFG Flash Sector. It is always set to 0x5555555555555555 and should be kept as-is. The value is a pattern which represents alternating 1s and 0s in binary. This is used to represent the condition of the Flash Sector to check for invalid programming such as this field being all 0xFF or 0x00.

⁽⁶⁾The value of this field will not be stored in a register. This value is fixed to 0 (does not dynamically change) and should be kept as-is. It is used by TI to indicate the version of SECCFG format.

9.8.5 SECCFG CRC

As an added security measure, the device boot ROM verifies the contents of the active CPU1 SECCFG sector using a CRC32 algorithm before loading the settings stored in the SECCFG sector into SSU registers. The SECCFG CRC is computed using the following parameters:

- **CRC Polynomial:** 0x04C1 1DB7 (CRC-32/ISO-HDLC)
- **Initial Value:** 0xFFFF FFFF
- **Final XOR Value:** 0xFFFF FFFF
- **Address Ranges:**

1. 0x000 to 0x6BF
2. 0x7A0 to 0x7F3
3. 0x7F8 to 0x7FF

Note

If the CRC check fails, bootROM remains in LINK0 and device fails to boot without ability for user to connect back to the device.

9.9 Flash Write/Erase Access Control

In addition to LINK, STACK and ZONE IDs, the SSU includes a Flash semaphore (FLSEM) to grant exclusive access to the Flash controller for programming, program verify, erase, and erase verify operations by a given initiator at any point in time. The Flash semaphore locks all data accesses to the Flash controller registers to a specific CPU and LINK. Upon receiving a command, the Flash Controller sends a permission request out through the Flash Crossbar port (FXB) to the SSU. The SSU then determines, based on the current security context and the FLSEM owner, whether to grant permission to execute the Flash command. Flash Controller operations are not permitted when the FLSEM has no owner.

The LINK, ZONE and CPU fields in the FLSEMSTAT register specify the current owner of the Flash semaphore. In addition, code running from any LINK can confirm ownership of the semaphore by reading the FLSEMSTAT.MATCH bit. This bit returns 1 only if the LINKID and CUID of the code performing the read match the current owner of the Flash semaphore. The FLSEMSTAT.ASSIGNED bit indicates whether the Flash semaphore is currently owned.

To grab the Flash semaphore:

1. Write 1 to the FLSEMREQ register.
2. Confirm ownership of the Flash semaphore by checking that FLSEMSTAT.MATCH = 1.

To release the Flash semaphore:

1. Write 1 to the FLSEMCLR register.
2. Confirm the Flash semaphore has been released by checking that FLSEMSTAT.MATCH = 0.

Note

With the Flash semaphore mechanism, configuring an access protection range to cover the Flash Controller registers is not necessary. Once the Flash semaphore has been assigned to a specific CPU ID and LINK ID, all accesses to the Flash Controller registers are restricted to that LINK, until the semaphore owner LINK releases the FLSEM by writing 1 to the FLSEMCLR register. In this way, the designated LINK can lock the Flash controller for exclusive self use, enabling code security and preventing access by other LINKs.

9.9.1 Permanent Flash Lock (Write/Erase Protection)

The SSU provides a mechanism to globally block program and erase operations to any Flash bank. To block all program and erase operations on code Flash banks throughout the device, write 1 to the WEPROT_CODE_BANKS.PROT register. To block program and erase operations to data Flash banks, write 1 to the WEPROT_DATA_BANKS.PROT register.

These protections can be hardened for safety or security purposes with the SSU's LOCK/COMMIT scheme using the following registers: WEPROT_CODE_BANKS_LOCK, WEPROT_CODE_BANKS_COMMIT, WEPROT_DATA_BANKS_LOCK, and WEPROT_DATA_BANKS_COMMIT.

Additionally, individual Flash sectors can be protected from write and erase operations using the WEPROT_FLCx_By_* registers. For each bank, there are two registers. The first, WEPROT_FLCx_By_A, contains individual protection bits for the first 32 sectors in bank y of Flash Controller x. The other, WEPROT_FLCx_By_B, defines protections for the remaining Flash sectors in the bank, in groups of 8 contiguous sectors. These registers also have LOCK and COMMIT mechanisms, similar to WEPROT_CODE_BANKS and WEPROT_DATA_BANKS.

All the Flash protection registers are mapped to the SECCFG sector, so that Flash protections defined in SECCFG are automatically loaded by the boot ROM at device start-up. Boot ROM does a bitwise interversion of the WEPROT values defined in SECCFG when loading from SECCFG to the SSU Registers. Using this mechanism, Flash bank or sector protections can be locked and committed before the application starts, and critical Flash contents remain unmodifiable throughout the current power-on cycle.

The Command Write Erase Protect (CMDWEPROT) registers, as part of FLASH_CMD_REGS_FLC1 and FLASH_CMD_REGS_FLC2, are OR'd with the SSU WEPROT registers. If either the WEPROT or CMDWEPROT registers indicate a sector/bank is protected then the protection takes place.

The BEPROT registers are flash erase status registers. For BEPROTA/BEPROTB, bank erase of a sector will occur if any of the below conditions is true:

- Device is in SSUMODE1
- In SSUMODE2, there exists APRs covering the region of Flash that is intended to be programmed
- In SSUMODE3, the corresponding ZONE has been given permission to be updated by the current CPU/LINK (Refer to Updating Flash Main Sectors section) and there exists APRs covering the region of Flash that is intended to be programmed.
- In SSUMODE3, ZONE is enabled for full debug, and there exists APRs covering the region of Flash that is intended to be programmed.

9.9.2 Updating Flash MAIN Sectors

For each ZONE, the user can configure a firmware update owner CPU and LINK using the FWU_CPU and FWU_LINK fields in the ZONEx_CFG register. The following restrictions apply when updating code in the Flash MAIN sectors:

- When in SSUMODE3, the firmware update owner CPU and LINK defined in the ZONEx_CFG register is the only LINK and CPU allowed to program and erase the Flash MAIN sectors. In addition, ZONEx_CFG.UPDATE_EN must be set to 0xC to enable updates.
 - While connected to the debugger, if a ZONE is enabled for full debug, then any LINK belonging to that ZONE can update the Flash MAIN sectors that correspond to an APR mapping to that ZONE.
 - While connected to the debugger, if ZONE1 is enabled for full debug then SECCFG/BANKMGMT Sectors can be programmed/erased by any LINK belonging to ZONE1.
- In SSUMODE1 and SSUMODE2, Flash write/erase protections are inactive as all ZONES are enabled for full debug.
 - **NOTE:** The Flash sectors/banks can be programmed or erased, as long as there is an APR covering the region of Flash that is being erased or programmed.

Flash Plugin Considerations

- The FlashPlugin requires the use of ERRORAREGATOR_BASE, ESMCPU1_BASE, CPUPERCFG_BASE, LPAX, LDA2-LDA0, and full Flash range. To be able to use the Flash Plugin (via CCS or Uniflash), ensure that ZONE1 is enabled for full debug (automatic under SSUMODE1/2) or give the LINK that will run the plugin read/write access to the APRs mentioned.
- **NOTE:** If SECCFG Update Owner CPU/LINK is not the same CPU/LINK update owner that is intended for the Flash Plugin while in SSUMODE3 then Flash Plugin can not update SECCFG Sectors. Please refer to the Hardcoded Protections section for a list of what can read the Flash SECCFG Sector while in SSUMODE3.
- **NOTE:** If APR registers are COMMITTED then the Flash Plugin will not be able to be used to program unless the required APRs for the Flash Plugin have R/W access given to the LINK that is intended for the Flash Plugin. The Flash Plugin re-writes the APRs required momentarily, while it executes, then resets the APRs back to user-defined APRs. However, if the APRs are committed then the Flash Plugin cannot reset the APRs.

9.9.3 Firmware-Over-The-Air Updates (FOTA)

This device supports Firmware-Over-The-Air (FOTA) updates using a Flash bank-swapping mechanism. The FOTA process is managed and controlled using the Flash Controller BANKMAP register and the BANKMGMT sector in each bank. Figure 9-5 shows an example of how banks are swapped.

When bank swap is active, all sectors of a Flash bank are swapped, including the SECCFG and BANKMGMT sectors.

Figure 9-5. Bank Swap Mapping Example

The FOTA concept is designed to enable programming of inactive Flash banks while the application continues to run from the active banks without interruption. The update process is comprised of the following steps:

1. **Image Creation and Deployment:** The user creates an application update image. This image can be transferred into the device using a Flash kernel, over a communications interface such as CAN or UART. The update image is typically delivered in chunks, since the RAM available is not large enough to hold an entire Flash image. For security, the update image can be authenticated using cryptographic methods such as a digital signature algorithm.
2. **Installation Phase:** The Flash kernel downloads Flash chunks, authenticates them, and programs them into the Flash update region (FRI-3). This phase consists of three steps:
 - a. Erase the inactive banks by addressing the update region with a Flash erase command.
 - b. Download, authenticate/decrypt and program updated firmware into the Flash update region.
 - c. Issue Flash API command to update BANKMGMT sector of inactive banks to be active and newer than the currently active banks. The Flash API commands are executed in the following order:
 - i. (CPU1 only) Program inactive bank's BANKMODE to the expected/new BANKMODE value. Note that changing the BANKMODE during a firmware update is possible.
 - ii. Program the inactive bank's BANK_UPDATE_CTR to be one less than the active bank's BANK_UPDATE_CTR.
 - iii. Program the inactive bank's BANK_STATUS to 0x55555555_55555555.
3. **Activation Phase:** The update manager waits for the application to reach a safe state (or brings the application to a safe state), then issues a full device reset (XRSn). A reset can be issued by software running in LINK2 by writing to the DEV_CFG_REGS.SIMRESET register. During device startup, the boot ROM reevaluates the BANKMGMT sectors, and configures BANKMAP to reflect the new update. After a timeout period, the FOTA manager requests the active firmware revision from the device. If the expected new version is not returned, the FOTA manager re-issues the update command, since the update has not completed successfully.

4. (Optional) **Rollback:** If desired, the user can return to the most recent (currently inactive) application firmware version. The rollback service erases and reprograms the current inactive BANKMGMT sector to be active and have a newer update counter value than the current active sector. This allows a rollback to the previous firmware version without having to re-download from an external interface. The rollback steps are executed in the following order:
 - a. Authenticate the code in the inactive bank to confirm the code's validity and integrity.
 - b. Erase the inactive bank's BANKMGMT sector.
 - c. (CPU1 only) Program inactive bank's BANKMODE to the correct BANKMODE value.
 - d. Program the inactive bank's BANK_UPDATE_CTR to one less than the active bank's BANK_UPDATE_CTR.
 - e. Program the inactive bank's BANK_STATUS to 0x55555555_55555555.
 - f. After bringing the application to a safe state, issue a device XRSn reset to activate the old firmware image.
5. (Optional) **Anti-Rollback:** To prevent any possibility of a rollback to the previous firmware version, invalidate the old firmware image completely by erasing the inactive bank's MAIN sectors.

9.9.4 Updating Flash SECCFG Sectors

The following security restrictions apply to updates of the SECCFG sectors:

- In SSUMODE1, all code running from any LINK has permission to update the SECCFG sectors, since ZONE1 is enabled for full debug. This enables ease of code development.
- In SSUMODE2, all code running from any LINK has permission to update SECCFG sectors, since ZONE1 is enabled for full debug.
- In SSUMODE3, only the SECCFG update owner defined in SECCFG_UPDATE_CFG has permission to update SECCFG sectors. In addition, SECCFG_UPDATE_CFG.UPDATE_EN must be set to 0xC to enable updates to SECCFG when operating in SSUMODE3.

Each CPU has two SECCFG sectors for storing User Protection Policy (UPP). One sector holds the active policy, while the other is available for updating. The SECVALID register specifies which of the two SECCFG sectors is active for each CPU subsystem.

When updating the SSU configuration, always program the SECCFG image to the reserve (B2/B3) SECCFG sector address, regardless of which sector is currently active. The SSU automatically routes the reserve address to the current inactive sector when a Flash program or erase command is performed. The SECCFG image base addresses are defined in [Table 9-3](#). However, CPU read operations must be addressed to the correct Flash read port address, as defined in [Section 9.8.3](#).

Table 9-3. CPU1 SECCFG Update Address Table

	CPU1/CPU2	CPU3	CPU1/CPU2 (FOTA/LFU)	CPU3 (FOTA/LFU)
Erase/Program	0x10D8 5000	0x10D9 5000	0x10D9 9000	0x10D9 D000
Read	Refer to Section 9.8.3			

9.9.5 Reading Flash SECCFG Sectors

As a countermeasure against overclocking attacks, all reads to Flash SECCFG sectors are hard-coded to 10 cycles (9 wait states), regardless of the current Flash wait state configuration.

9.10 RAMOPEN Feature

The RAMOPEN mode provides a means for bootloader applications to exclusively access RAM for the purpose of storing code or data downloaded from an external source. RAMOPEN can only be initiated by two sources:

1. Direct JTAG writes to the RAMOPENFRC register. This gives the debugger the ability to open RAM access for writing before downloading code to the RAM. Debugger writes to LINK1 RAM are only allowed in SSUMODE1, in SSUMODE2, or when ZONE1 is enabled for full debug.
2. Boot loader code running in LINK1.

RAMOPEN cannot be initiated by code running from any of the user LINKs (2 and above).

When RAMOPEN is opened, the following sequence occurs:

1. The hardware erases the RAMs using RAMINIT.
2. Any write to RAM that was initiated prior to or during RAMINIT is aborted. Write accesses can only update RAM after RAMINIT completes and RAMOPEN status becomes active.
3. LINK1 gains read, write and execute permissions for RAMOPENed memories. All other LINKs have no access to any of the RAMs.
4. The SSU sets RAMOPENSTAT.LINK1_RAMOPENS to 1 to indicate RAMOPEN is now active.

After the intended use for RAMOPEN completes, return the RAM back to the user application by writing 1 to the RAMOPENCLR.CLEAR_LINK1 register. Once the bit has been written, if the RAMOPENFRC.WIPE_ON_LINK1_CLR bit is set, the device erases the RAM content for all RAMOPENed memories using the RAMINIT feature, and then clears the RAMOPENSTAT.LINK1_RAMOPENS bit. If the RAMOPENFRC.WIPE_ON_LINK1_CLR bit was not set, then the RAM contents are preserved when RAM is returned to the user application. This feature gives user bootloaders (for example, firmware updaters) the ability to automatically wipe sensitive data or code from the RAM after the bootloader operation completes.

The following sequence occurs when RAMOPENCLR.CLEAR_LINK1 is written:

1. If RAMOPENFRC.WIPE_ON_LINK1_CLR is set, then the RAMs are erased using RAMINIT.
2. Any write to RAM that was initiated prior to or during RAMINIT is aborted. Only writes initiated after RAMINIT completes and RAMOPEN status is set to inactive update the RAM.
3. RAM access permissions are allocated according to the configured user protection policy (UPP).
4. The SSU sets RAMOPENSTAT.LINK1_RAMOPENS to 0 to indicate RAMOPEN is now inactive.

Note

In RAMOPEN mode, unauthorized code can be loaded into memory as LINK1 code. Any ZONEs that permit firmware updates from the LINK1 can be updated without user code control. The most secure way to perform a firmware update is to lock boot loaders down and use a secure firmware update algorithm.

	Enabled	Start Address	End Address	Comment
CPU1.LINK1	Yes	0x200E 0000	0x2010 FFFF	RAM used by bootloaders. Includes all LDAX and LPAX RAMs.
All other LINKs	No	N/A	N/A	N/A

9.11 Booting of CPU2 and CPU3

The SSU_CPU2_CFG_REGS and SSU_CPU3_CFG_REGS, respectively, hold the reset and boot settings for CPU2 and CPU3. As part of the boot process, CPU1's reset vector is hardcoded to LINK0 ROM. A detailed description of the Boot ROM sequence is explained in the [Device Boot Sequence](#) section. The application code for CPU1 needs to initialize the other core's reset vector and reset LINK register (RST_VECT and RST_LINK) before releasing reset to those cores (CPU_RST_CTRL). These instructions in CPU1 application code need to

be ran in the context of CPU1.LINK2. An example of this configuration is show in the F29 SDK SSU multi-core examples.

9.12 Debug Authorization

There are two levels of debug authorization provided by the SSU:

- Global JTAG authorization (C29DBGEN)
- ZONE debug authorization

Debug access control features are active in SSUMODE3. In SSUMODE1 and SSUMODE2, JTAG is automatically enabled, and all user ZONES are enabled for full debug.

9.12.1 Global CPU Debug Enable

The global debug enable control gates debug access to all C29x CPU test access ports (TAPs). When C29DBGEN is inactive (set to 0), none of the CPU cores are accessible directly using JTAG; only communication with the device Security Access Port (SEC-AP) handler is permitted. SEC-AP provides an available secure communication port through which the user can perform authentication requests. The registers associated with SEC-AP are described in the C29DEBUGSS Registers.

When present, the HSM can also control debug access to the C29x CPUs by writing to the C29DBGEN or ZONE_DBGEN registers in the SSU.

Note

C29DBGEN only controls debug access to the C29x CPUs, and has no effect on HSM debug access. C29DBGEN is different from the HSM global JTAG disable control (JTAG_DIS) which blocks access to all device debug ports permanently, including both HSM and C29x CPU subsystems.

9.12.2 ZONE Debug

In addition to the global C29x debug enable control, each ZONE has a separate enable setting, for more granular debug access control. ZONES can span one or more CPUs, and are orthogonal to individual CPU TAP enables. ZONES can be used to separate debug authorization across different parts of the device between different users, with different authentication credentials established for each user. When a user performs a debug access to a memory region, the SSU checks to see if at least one LINK with the requested access to the region belongs a ZONE that has been enabled for full debug. If no LINKs match this condition, then the SSU blocks the debug access, and notifies the C29x SEC-AP handler that a debug read or write error occurred, depending on the type of access attempted.

9.12.3 Authentication for Debug Access

The DEBUG_CFG register controls the authentication method used to control debug access at the C29DBGEN level and each of the user ZONE debug levels. For each debug access control, there are two valid configuration options:

- Password-based authentication
- Debug disabled

The DEBUG_CFG register has LOCK/COMMIT protections to prevent unintended or unauthorized changes to the debug authentication scheme. To lock or commit these settings, write to the DEBUG_CFG_LOCK and DEBUG_CFG_COMMIT registers as required.

The current debug status for C29DBGEN and each of the user debug ZONES can be determined by connecting to the SEC-AP interface and reading the DEBUG_ENABLE_STATUS register. For more details, see the SEC-AP gel file, which contains a script to read the DEBUG_ENABLE_STATUS register. GEL files are located in the following CCS installation directory: C:\ti\ccs_version\ccs\ccs_base\emulation\gel.

Devices shipped from the TI factory have password-based authentication active at boot-up by default. The passwords are all setup for a default of all 0x5's (128 bit passwords). The SSU Tool in SysConfig and SEC-AP GEL File also have all 0x5s as the default passwords. To change the startup debug authentication mode, update the DEBUG_CFG field in the SECCFG sector accordingly.

9.12.3.1 Password-based Authentication

When password-based authorization is enabled for C29DBGEN or a user ZONE, the associated register bit field (C29DBGEN.ENA, ZONE_DBG.ZONEx) is ignored by the SSU. Instead, the user scans a 128-bit password into the appropriate internal key register using the SEC-AP, and the SSU hardware compares the scanned-in password to a predefined password that is preloaded from the SECCFG sector during device boot. If the password matches, then the SSU opens debug access to the requested resource.

There are two levels of ZONE debug authorization that can be enabled by password authentication: full debug, and partial debug. These are controlled using the full debug password and partial debug password respectively. When a user scans in a password for debug authorization, the SSU performs the following sequence:

1. Compare scanned-in password to full debug password. If matching, then open the ZONE for full debug.
2. If the previous compare resulted in a mismatch, then compare the scanned-in password to the partial debug password. If matching, then open the ZONE for partial debug.
3. If the previous compare resulted in a mismatch, then the ZONE remains closed.

To enable C29DBGEN or open debug access to a zone when using password-based authentication, scan the appropriate command as defined in [Table 9-4](#) into the SEC-AP PASSWORD_ID register, and then scan in the 128-bit password into the SEC-AP password registers (PASSWORD1 [31:0], PASSWORD2 [63:32], PASSWORD3 [95:64], PASSWORD4 [127:96]). Refer to the SEC-AP gel file for an example of how to scan in the scan command and 128-bit password through the SEC-AP interface using these registers. Note that there is a single password scan required for both full and partial ZONE debug. The SSU first compares the scanned in password to the full debug password. If there is a match, then full debug is enabled for the ZONE. If there is a mismatch, then the SSU compares the scanned in password to the partial debug password to determine whether to enable partial debug for the ZONE.

The debug sub-system registers contain more information on the password registers in SEC-AP. For details on how to utilize the System Security Tool in SysConfig to enable password-based Authentication refer to the Debug Authorization chapter of the [Implementing Run-Time Safety and Security With the C29x Safety and Security Unit](#) application note.

Table 9-4. Password Scan Commands

Value	Command
0x0	Reserved for internal use
0x1	ZONE1 Debug Password Scan
0x2	ZONE2 Debug Password Scan
0x3	ZONE3 Debug Password Scan
0x4	C29DBGEN Unlock Password Scan
Others	Reserved for future use

For C29DBGEN, there is only one password that controls debug access. When the user scans in a password matching the C29DBGEN password, the SSU unlocks the Test Access Ports (TAPs) for all application CPUs in the device. The HSM also has control over the application CPU TAPs. When the HSM is present, both C29DBGEN and the corresponding HSM debug enable control must be active for debug access to the C29x CPU TAP to be opened. If either C29DBGEN or the HSM denies access, then the C29x CPU TAP remains closed.

Note

The SSU has no control over HSM resources. C29DBGGEN only controls debug access to C29x CPUs. For information on how to enable debug access to the HSM, see the [F29x Security Hardware User Guide](#).

C29DBGGEN does not override ZONE debug authorization. Even with C29DBGGEN active, a password-protection ZONE must still be unlocked for the debugger to access any memory-mapped resources in that ZONE. C29DBGGEN only controls access to the CPU TAPs.

9.13 Hardcoded Protections

The user has the ability to configure all LINKs, STACKs and ZONEs that are owned by the user. However, certain system resources have protections that are fixed in hardware and cannot be altered:

- LINK0 belongs to STACK0, and STACK0 belongs to ZONE0. These are TI internal resources and cannot be accessed by user code. User code cannot assign any user LINKs to STACK0, or user STACKs to ZONE0.
- LINK1 for each CPU always belongs to STACK1.
- STACK1 for each CPU always belongs to ZONE1.
- LINK2 for each CPU always belongs to STACK2.
- STACK2 for each CPU always belongs to ZONE1.
- In SSUMODE3, the Flash SECCFG sector can only be read by:
 - The SECCFG update owner defined in SECCFG_UPDATE_CFG, or
 - The HSM, if present and enabled.
- Code instruction fetches to M0 memory always generate a fault.
- Data reads of M0 RAM are allowed for all CPUs and all LINKs.
- Data writes to M0 RAM are only allowed for CPU1.LINK2.
- Certain memory and peripheral regions are restricted to one or more of the special-purpose LINKs (LINK0, LINK1 and LINK2). For details on these non-APR-based memory protections, refer to the memory-map in the device data sheet.

9.14 SSU Register Access Permissions

SSU register permissions vary depending on category and function. CPU1 is the primary owner of all SSU registers, including those for all other CPUs. Most registers are automatically loaded at device startup; however, some are designated for run-time operation, for example, FLSEM. The tables in this section describe the access permissions for each register, organized by register groups. For register access permission tables that do not include a column for the HSM, there is no HSM access permitted to these registers.

Accesses to SSU registers that are denied generate a fault to the ESM.

Note

When lockstep mode is enabled, the register access permissions for the secondary CPU are always identical to the access permissions for the primary CPU. For instance, if CPU2 is present and in lockstep with CPU1, then CPU2's access permissions are the same as CPU1's. The CPU2 permission tables do not apply. For more information on SSU operation in lockstep mode, see [Section 9.6.1](#).

In SSUMODE1, CPU register read access is granted if any LINK is enabled for hardcoded read permissions. Similarly, in SSUMODE1 CPU register write access is granted if any LINK is enabled for hardcoded write permissions. This rule does not supersede Flash semaphore ownership rules.

9.14.1 Permissions for SSU General Control Registers

[Table 9-5](#) describes access permissions for the SSU_GEN_REGS group of registers.

Table 9-5. Access Permissions for SSU General Control Registers

Register	Register Load Method	Boot	CPU1				CPU2+			HSM
			CPU1 LINK1	CPU1 LINK2	CPU1 LINK3+	CPU1 Debug	CPU2+ LINK0,1, and 3+	CPU2+ LINK2	CPU2+ Debug

(1) If any ZONE is enabled for partial or full debug (note that this occurs automatically when SSUMODE = 1 or 2); otherwise, no access.

(2) If ZONE1 is enabled for full debug (note that this occurs automatically when SSUMODE = 1 or 2); otherwise, R-only (with note 1 applied).

(3) Only writable if FLSEMSTAT.ASSIGNED is set and FLSEMSTAT.CPU and FLSEMSTAT.LINK match the transaction's CPUID/LINKID sideband signals.

(4) BANKMAP registers are R/W by CPU1.LINK2 when HSM is in HS-FS state. This allows C29x FW to control updates on non-HSM (or not-secured-yet HSM devices).

(5) FLSEMCLR is only writable if FLSEMSTAT.ASSIGNED is set and FLSEMSTAT.CPU and FLSEMSTAT.LINK match the transaction's CPUID/LINKID, or if the transaction's CPUID.LINKID is CPU1.LINK2.

9.14.2 Permissions for SSU CPU1 Configuration Registers

Table 9-6 describes access permissions to the SSU_CPU1_CFG_REGS register group. This group of registers is not accessible by the HSM.

Table 9-6. Access Permissions for SSU CPU1 Configuration Registers

Register	Register Load Method	Boot	CPU1				CPU2+	
			CPU1 LINK1	CPU1 LINK2	CPU1 LINK3+	CPU1 Debug	CPU2+ LINK0+	CPU2+ Debug
EMU_BOOTDEF_LOW	None	R-only	R-only	R-only	R-only	R/W ⁽¹⁾	No	No
EMU_BOOTDEF_HIGH	None	R-only	R-only	R-only	R-only	R/W ⁽¹⁾	No	No
LINKx_CFG	Boot	R/W	R-only	R-only	R-only	R-only ⁽¹⁾	No	No
STACKy_CFG	Boot	R/W	R-only	R-only	R-only	R-only ⁽¹⁾	No	No
RAMOPENSTAT	None	R-only	R-only	R-only	R-only	R-only ⁽¹⁾	No	No
RAMOPENFRC	Boot	R/W	R/W	R-only	R-only	R/W ⁽¹⁾	No	No
RAMOPENCLR	Boot	R/W	R/W	R-only	R-only	R/W ⁽¹⁾	No	No
DECODER_ADDR_IN	None	R/W	No	R/W	No	No	No	No
DECODER_OUT	None	R-only	No	R-only	No	No	No	No
EMU_DECODER_ADDR_IN	None	No	No	No	No	R/W ⁽¹⁾	No	No
EMU_DECODER_OUT	None	No	No	No	No	R-only ⁽¹⁾	No	No

(1) If ZONE1 is enabled for full debug (note that this occurs automatically when SSUMODE=1 or 2); otherwise, no access.

9.14.3 Permissions for SSU CPU2+ Configuration Registers

Table 9-7 describes the access permissions for the SSU_CPUx_CFG_REGS register groups. This register group exists for each additional CPU present in the device, beginning with CPU2.

Table 9-7. Access Permissions for SSU CPU2/CPU3 Configuration Registers

Register	Boot Load Method	Boot	CPU1			CPU _n					Other CPUs
			CPU1 LINK1	CPU1 LINK2+	CPU1 Debug	CPU _n LINK0	CPU _n LINK1	CPU _n LINK2	CPU _n LINK3+	CPU _n Debug	
RST_VECT	Boot	R/W	R-only	R-only	R-only ⁽¹⁾	R-only	R-only	R-only	R-only	R-only ⁽¹⁾	No
RST_LINK	Boot	R/W	R-only	R-only	R-only ⁽¹⁾	R-only	R-only	R-only	R-only	R-only ⁽¹⁾	No
CPU_RST_CTRL	None	R-only	R-only	R/W	R-only ⁽¹⁾	R-only	R-only	R-only	R-only	R-only ⁽¹⁾	No ⁽³⁾

(1) If any ZONE is enabled for partial or full debug (note that this occurs automatically when SSUMODE=1 or 2); otherwise, no access.

(2) f ZONE1 is enabled for full debug (note that this occurs automatically when SSUMODE=1 or 2); otherwise, no access.

(3) With exception: the primary CPU's LINK2 has access to modify (R/W) the secondary CPU's CPU_RST_CTRL register. For instance, CPU3.LINK2 has R/W access to CPU_RST_CTRL for CPU4, if present.

9.14.4 Permissions for CPU1 Access Protection Registers

Table 9-8 describes access permissions for the SSU_CPU1_AP_REGS register group. The HSM has no access to these registers.

Table 9-8. Access Permissions for CPU1 Access Protection Registers

Register	Boot Load Method	Boot	CPU1				CPU2+	
			CPU1 LINK1	CPU1 LINK2	CPU1 LINK3+	CPU1 Debug	CPU2+ LINK0+	CPU2+ Debug
APn_CFG	Boot	R/W	R/W ⁽¹⁾	R/W	R-only	R/W ⁽²⁾	No	No
APn_START[_EXT]	Boot	R/W	R/W ⁽¹⁾	R/W	R-only	R/W ⁽²⁾	No	No
APn_END[_EXT]	Boot	R/W	R/W ⁽¹⁾	R/W	R-only	R/W ⁽²⁾	No	No
APn_LOCK	Boot	R/W	R/W ⁽¹⁾	R/W	R-only	R/W ⁽²⁾	No	No
APn_COMMIT	Boot	R/W	R/W ⁽¹⁾	R/W	R-only	R/W ⁽²⁾	No	No
APn_ACCESS	Boot	R/W	R/W ⁽¹⁾	R/W	R-only	R/W ⁽²⁾	No	No

(1) If in SSUMODE1 or SSUMODE2; otherwise, no access.

(2) If ZONE1 is enabled for full debug (note that this occurs automatically when SSUMODE=1 or 2); otherwise, no access.

9.14.5 Permissions for CPU2+ Access Protection Registers

Table 9-9 describes access permissions for the SSU_CPUn_AP_REGS register group or groups, starting with CPU2, for each additional CPU present in a multicore device. The HSM does not have access to these registers.

Table 9-9. Access Permissions for CPU2+ Access Protection Registers

Register	Boot Load Method	Boot	CPU1				CPUn				Other CPUs
			CPU1 LINK1	CPU1 LINK2	CPU1 LINK3+	CPU1 Debug	CPUn LINK0/1	CPUn LINK2	CPUn LINKs	CPUn Debug	
APn_CFG	Boot	R/W	R/W ⁽¹⁾	R/W	No	R/W ⁽²⁾	R-only	R/W	R-only	R/W ⁽²⁾	No
APn_START[_EXT]	Boot	R/W	R/W ⁽¹⁾	R/W	No	R/W ⁽²⁾	R-only	R/W	R-only	R/W ⁽²⁾	No
APn_END[_EXT]	Boot	R/W	R/W ⁽¹⁾	R/W	No	R/W ⁽²⁾	R-only	R/W	R-only	R/W ⁽²⁾	No
APn_LOCK	Boot	R/W	R/W ⁽¹⁾	R/W	No	R/W ⁽²⁾	R-only	R/W	R-only	R/W ⁽²⁾	No
APn_COMMIT	Boot	R/W	R/W ⁽¹⁾	R/W	No	R/W ⁽²⁾	R-only	R/W	R-only	R/W ⁽²⁾	No
APn_ACCESS	Boot	R/W	R/W ⁽¹⁾	R/W	No	R/W ⁽²⁾	R-only	R/W	R-only	R/W ⁽²⁾	No

(1) If in SSUMODE1 or SSUMODE2; otherwise, no access.

(2) If ZONE1 is enabled for full debug (note that this occurs automatically when SSUMODE=1 or 2); otherwise, no access.

9.15 SSU Fault Signals

The Safety and Security Unit can generate faults to two different interfaces: the C29x CPU interface, and the Error Aggregator interface that forwards error signals to the Error Signaling Module (ESM). In general, errors that occur as a result of an unauthorized CPU access to a protected memory region generate a fault signal to the CPU, while other types of errors generate a fault signal to the Error Aggregator. The following tables describe the various faults that are generated by the SSU to the CPU and Error Aggregator interfaces. Because the SSU interfaces between the CPU and Flash Controllers for performing program and erase operations, the SSU also reports errors generated by the Flash Controllers to the Error Aggregator. These errors are described in Table 9-11 and Table 9-12.

Table 9-10. SSU to C29x CPU Fault Signals

Security Fault	Error Type	Bus	Error Description
CPUx_PR_HIGHPRIO_ERROR	0x01	Program Bus	This error is generated when a program read occurs, and the address is not covered by a hardcoded protection or a currently active RAMOPEN region, and one of the following is true: - Zero or more than one AP regions respond, or - The responding AP region's XE bit is set to 0, or - The responding AP region's LINKID field is set to 0, or - The responding AP region's LINKID decodes to STACK0 or ZONE0
CPUx_DR1_HIGHPRIO_ERROR	0x01	Data Read Bus 1	This error is generated when a CPU data read occurs on DRB1, and zero or more than one AP region responds with valid read access permissions for the instruction's LINK.
CPUx_DR2_HIGHPRIO_ERROR	0x01	Data Read Bus 2	This error is generated when a CPU data read occurs on DRB2, and zero or more than one AP region responds with valid read access permissions for the instruction's LINK.
CPUx_DW_HIGHPRIO_ERROR	0x01	Data Write Bus	This error is generated when a CPU data write occurs, and zero or more than one AP region responds with valid write access permissions for the instruction's LINK.

Table 9-11. SSU to Error Aggregator Fault Signals

Error Signal	Description	Error Address	Priority
SSU_ERROR_TYPE[0]	HSM SSU Register Access Error	SSU register address	High
SSU_ERROR_TYPE[1]	CPU1 SSU Register Access Error	SSU register address	High
SSU_ERROR_TYPE[2]	CPU2 SSU Register Access Error	SSU register address	High
SSU_ERROR_TYPE[3]	CPU3 SSU Register Access Error	SSU register address	High
SSU_ERROR_TYPE[4]	Reserved	-	-
SSU_ERROR_TYPE[6:5]	Reserved	-	-
SSU_ERROR_TYPE[7]	Invalid BANKMAP, SECVALID, BANKMODE or SSUMODE	N/A	High
SSU_ERROR_TYPE[8]	Error on Flash Controller 1	See Table 9-12	High
SSU_ERROR_TYPE[11:9]	FLC1 Error Type		High
SSU_ERROR_TYPE[12]	FLC1 Register Access Error	FLC1 register address	High
SSU_ERROR_TYPE[13]	Error on Flash Controller 2	See Table 9-12	High
SSU_ERROR_TYPE[16:14]	FLC2 Error Type		High
SSU_ERROR_TYPE[17]	FLC2 Register Access Error	FLC2 register address	High

Table 9-12. Flash Controller Error Codes

Error Code	Error Name	Description	Error Address
0x0	ILLADDR	Controller reported an out of range/illegal Flash address, or a security violation.	Flash address
0x1	ILLPROG	An error occurred while trying to execute a programming command.	
0x2	ILLERASE	An error occurred while trying to execute an erase command.	
0x3	ILLRDVER	The Flash Controller failed to completely program or erase all target bits in the Flash within the maximum number of pulses.	
0x4	ILLMODECH	An attempt was made to execute a program or erase command while the Flash was not in READ mode. The erase/program command was aborted.	
0x5	ILLCMD	An illegal command was issued to the Flash Controller.	Command type
0x6	ILLSIZE	An illegal size value was provided for the Flash Controller command.	Command size
0x7	ILLBANKERASE	An error occurred while trying to execute a bank erase command.	Flash address

9.17 SSU Registers

This section describes the SSU Registers.

9.17.1 SSU Base Address Table

Table 9-14. SSU Base Address Table

Structure	DriverLib Name	Base Address	Frame Applicable	CPU1	CPU2	CPU3	RTDMA1	RTDMA2	HSM	Pipeline Protected
SSU_GEN_REGS	SSUGEN_BASE	0x3008_0000	-	YES	YES	YES	-	-	YES	YES
SSU_CPU1_CFG_REGS	SSUCPU1CFG_BASE	0x3008_1000	-	YES	-	-	-	-	-	YES
SSU_CPU2_CFG_REGS	SSUCPU2CFG_BASE	0x3008_2000	-	YES	YES	-	-	-	-	YES
SSU_CPU3_CFG_REGS	SSUCPU3CFG_BASE	0x3008_3000	-	YES	-	YES	-	-	-	YES
SSU_CPU1_AP_REGS	SSUCPU1AP_BASE	0x3008_7000	-	YES	-	-	-	-	-	YES
SSU_CPU2_AP_REGS	SSUCPU2AP_BASE	0x3008_8000	-	YES	YES	-	-	-	-	YES
SSU_CPU3_AP_REGS	SSUCPU3AP_BASE	0x3008_9000	-	YES	-	YES	-	-	-	YES

9.17.2 SSU_GEN_REGS Registers

Table 9-15 lists the memory-mapped registers for the SSU_GEN_REGS registers. All register offset addresses not listed in Table 9-15 should be considered as reserved locations and the register contents should not be modified.

Table 9-15. SSU_GEN_REGS Registers

Offset	Acronym	Register Name	Protection
0h	REVISION	Module Revision Register	
4h	UPP_REVISION	User Protection Policy Revision	
8h	SSUMODE	Safety and Security Operational Mode	
Ch	LINK2_AP_OVERRIDE	LINK2 Access Protection Override Register	
30h	EMU_BOOTPIN_CONFIG	User Emulation Boot Pin Configuration	
3Ch	EMU_BOOTEN	User Emulation Boot Enable	
40h	RAMOPEN_LOCK	RAMOPEN Feature Lock Register	
44h	RAMOPEN_COMMIT	RAMOPEN Feature Commit Register	
4Ch	CPUID	CPUID Register	
50h	BANKMAP	Valid Banks	
54h	BANKMAP_LOCK	Bank Map Lock Register

3B4h	WEPROT_FLC2_B0_COMMIT	Flash Controller 2 B0 WEPROTA Commit	
3E0h	WEPROT_FLC2_B2_A	Flash Controller 2 B2 Write Erase Protection A	
3E4h	WEPROT_FLC2_B2_B	Flash Controller 2 B2 Write Erase Protection B	
3F0h	WEPROT_FLC2_B2_LOCK	Flash Controller 2 B2 WEPROTA Lock	
3F4h	WEPROT_FLC2_B2_COMMIT	Flash Controller 2 B2 WEPROTA Commit	

Complex bit access types are encoded to fit into small table cells. [Table 9-16](#) shows the codes that are used for access types in this section.

Table 9-16. SSU_GEN_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
WOnce	W Once	Write Write once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

9.17.2.1 REVISION Register (Offset = 0h) [Reset = 00000000h]

REVISION is shown in [Figure 9-6](#) and described in [Table 9-17](#).

Return to the [Summary Table](#).

Module Revision Register

Table 9-17. REVISION Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	RESERVED	R	0h	Reserved
23-16	RESERVED	R	0h	Reserved
15-8	MAJREV	R	0h	This hardcoded field defines the major revision of the IP. Reset type: XRSn
7-0	MINREV	R	0h	This hardcoded field defines the minor revision of the IP. Reset type: XRSn

9.17.2.2 UPP_REVISION Register (Offset = 4h) [Reset = 00000000h]

UPP_REVISION is shown in [Figure 9-7](#) and described in [Table 9-18](#).

Return to the [Summary Table](#).

User Protection Policy Revision

Figure 9-7. UPP_REVISION Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																REV															
R-0h																R/W-0h															

Table 9-18. UPP_REVISION Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	Reserved
15-0	REV	R/W	0h	Defines the User Protection Policy revision number stored in the SECCFG sectors. Reset type: XRSn

9.17.2.3 SSUMODE Register (Offset = 8h) [Reset = 00000003h]

SSUMODE is shown in [Figure 9-8](#) and described in [Table 9-19](#).

Return to the [Summary Table](#).

Safety and Security Operational Mode

Figure 9-8. SSUMODE Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																RESERVED										OPMODE					
R-0h																R-0h										R/WOnce-3h					

Table 9-19. SSUMODE Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	Reserved
15-6	RESERVED	R	0h	Reserved
5-0	OPMODE	R/WOnce	3h	Defines the operational mode of the SSU. 0x03 : SSUMODE3 mode (recommended) 0x0C : SSUMODE2 mode 0x30 : SSUMODE1 mode Others : Invalid and generates a fault. Reset type: XRSn

9.17.2.4 LINK2_AP_OVERRIDE Register (Offset = Ch) [Reset = 00000000h]

LINK2_AP_OVERRIDE is shown in [Figure 9-9](#) and described in [Table 9-20](#).

Return to the [Summary Table](#).

LINK2 Access Protection Override Register
